FortiOS 7.4.1 Administration Guide

01-741-902083-20230831

TABLE OF CONTENTS

Change Log	24
Getting started	25
Differences between models	25
Low encryption models	25
Using the GUI	25
Connecting using a web browser	26
Menus	26
Tables	27
Entering values	31
GUI-based global search	33
Loading artifacts from a CDN	34
Accessing additional support resources	34
Command palette	35
Recovering missing graphical components	37
Using the CLI	39
Connecting to the CLI	39
CLI basics	42
Command syntax	48
Subcommands	50
Permissions	53
FortiExplorer management	53
Getting started with FortiExplorer	54
Connecting FortiExplorer to a FortiGate with WiFi	57
Configure FortiGate with FortiExplorer using BLE	58
Running a security rating	61
Upgrading to FortiExplorer Pro	62
Basic administration	62
Basic configuration	63
Registration	65
FortiCare and FortiGate Cloud login	67
Transfer a device to another FortiCloud account	70
Configuration backups	72
Deregistering a FortiGate	81
Migrating a configuration with FortiConverter	82
Fortinet Developer Network access	88
One-time upgrade prompt when a critical vulnerability is detected upon login NEW	92
LEDs	93
Alarm levels	98
Troubleshooting your installation	98
Dashboards and Monitors	101
Using dashboards	101
Using widgets	103
Widgets	104
Viewing device dashboards in the Security Fabric	107

Creating a fabric system and license dashboard	108
Example	108
Dashboards	109
Resetting the default dashboard template	109
Status dashboard	110
Security dashboard	113
Network dashboard	115
Assets & Identities	122
WiFi dashboard	127
Monitors	133
Non-FortiView monitors	133
FortiView monitors	133
FortiView monitors	134
Adding FortiView monitors	135
Using the FortiView interface	138
Enabling FortiView from devices	141
FortiView sources	144
FortiView Sessions	145
FortiView Top Source and Top Destination Firewall Objects monitors	147
Viewing top websites and sources by category	148
Cloud application view	151
Network	161
Interfaces	161
Interface settings	163
Physical interface	188
VLAN	189
Aggregation and redundancy	205
Loopback interface	213
Software switch	214
Hardware switch	216
Zone	220
Virtual wire pair	222
Enhanced MAC VLAN	229
VXLAN	232
DNS	268
Important DNS CLI commands	269
DNS domain list	272
FortiGate DNS server	274
DDNS	276
DNS latency information	280
DNS over TLS and HTTPS	282
Transparent conditional DNS forwarder NEW	286
DNS troubleshooting	290
Explicit and transparent proxies	292
Explicit web proxy	292
FTP proxy	296
Transparent proxy	300
Proxy policy addresses	302

Proxy policy security profiles	309
Explicit proxy authentication	313
Transparent web proxy forwarding	320
Upstream proxy authentication in transparent proxy mode	323
Multiple dynamic header count	325
Restricted SaaS access	327
Explicit proxy and FortiGate Cloud Sandbox	336
Proxy chaining	338
WAN optimization SSL proxy chaining	343
Agentless NTLM authentication for web proxy	351
Multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers	354
Learn client IP addresses	355
Explicit proxy authentication over HTTPS	356
mTLS client certificate authentication	358
CORS protocol in explicit web proxy when using session-based, cookie-enabled, and captive portal-enabled SAML authentication	363
Display CORS content in an explicit proxy environment NEW	367
HTTP connection coalescing and concurrent multiplexing for explicit proxy	369
Secure explicit proxy	371
Explicit proxy logging	374
Configuring fast fallback for explicit proxy NEW	379
Forward HTTPS requests to a web server without the need for an HTTP CONNECT message NEW	382
DHCP servers and relays	384
Default DHCP server for low-end FortiGates	384
Basic configuration	385
DHCP options	388
DHCP addressing mode on an interface	395
VCI pattern matching for DHCP assignment	398
DHCP shared subnet	400
DHCP smart relay on interfaces with a secondary IP	401
FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses	403
Static routing	403
Routing concepts	404
Policy routes	418
Equal cost multi-path	421
Dual internet connections	425
Dynamic routing	430
RIP	432
OSPF	451
BGP	468
BFD	516
Routing objects	526
Multicast	535
Multicast routing and PIM support	535
Configuring multicast forwarding	536
FortiExtender	540
WAN extension mode	540

LAN extension mode	540
Adding a FortiExtender	541
Direct IP support for LTE/4G	543
Sample LTE interface	544
Limitations	545
Active SIM card switching	546
Example 1	547
Example 2	548
LLDP reception	550
Virtual routing and forwarding	553
Implementing VRF	553
VRF routing support	554
Route leaking between VRFs with BGP	560
Route leaking between multiple VRFs	562
VRF with IPv6	573
IBGP and EBGP support in VRF	576
Support cross-VRF local-in and local-out traffic for local services	579
NetFlow	581
Verification and troubleshooting	582
NetFlow templates	583
NetFlow on FortiExtender and tunnel interfaces	595
sFlow	599
Configuring sFlow	599
Link monitor	602
Link monitor with route updates	602
Enable or disable updating policy routes when link health monitor fails	604
Add weight setting on each link health monitor server	606
SLA link monitoring for dynamic IPsec and SSL VPN tunnels	609
IPv6	612
IPv6 overview	612
IPv6 quick start	613
Neighbor discovery proxy	617
IPv6 address assignment	618
NAT66, NAT46, NAT64, and DNS 64	630
DHCPv6 relay	640
IPv6 tunneling	641
IPv6 configuration examples	652
FortiGate LAN extension	684
Diagnostics	690
Using the packet capture tool	690
Using the debug flow tool	696
SD-WAN	700
SD-WAN overview	700
SD-WAN components and design principles	700
SD-WAN designs and architectures	703
SD-WAN quick start	704
Configuring the SD-WAN interface	704

Adding a static route	706
Selecting the implicit SD-WAN algorithm	706
Configuring firewall policies for SD-WAN	707
Link monitoring and failover	707
Results	708
Configuring SD-WAN in the CLI	711
SD-WAN members and zones	713
Topology	714
Configuring SD-WAN member interfaces	714
Configuring SD-WAN zones	716
Using SD-WAN zones	717
Specify an SD-WAN zone in static routes and SD-WAN rules	719
Defining a preferred source IP for local-out egress interfaces on SD-WAN members	724
Performance SLA	725
Performance SLA overview	726
Link health monitor	731
Monitoring performance SLA	733
Passive WAN health measurement	737
Passive health-check measurement by internet service and application	743
Mean opinion score calculation and logging in performance SLA health checks	746
Embedded SD-WAN SLA information in ICMP probes	749
SD-WAN application monitor using FortiMonitor	757
Classifying SLA probes for traffic prioritization	761
SD-WAN rules	766
SD-WAN rules overview	767
Implicit rule	775
Automatic strategy	779
Manual strategy	780
Best quality strategy	783
Lowest cost (SLA) strategy	787
Load balancing strategy NEW	793
Manual interface speedtest	794
Scheduled interface speedtest	795
SD-WAN traffic shaping and QoS	796
SDN dynamic connector addresses in SD-WAN rules	801
Application steering using SD-WAN rules	804
DSCP tag-based traffic steering in SD-WAN	817
ECMP support for the longest match in SD-WAN rule matching	824
Override quality comparisons in SD-WAN longest match rule matching	826
Internet service and application control steering	829
Use maximize bandwidth to load balance traffic between ADVPN shortcuts	838
Use SD-WAN rules to steer multicast traffic	845
Advanced routing	858
Local out traffic	858
Using BGP tags with SD-WAN rules	864
BGP multiple path support	868
Controlling traffic with BGP route mapping and service rules	870
Applying BGP route-map to multiple BGP neighbors	877
Using multiple members per SD-WAN neighbor configuration	883

VPN overlay	889
ADVPN and shortcut paths	889
Active dynamic BGP neighbor triggered by ADVPN shortcut NEW	902
SD-WAN monitor on ADVPN shortcuts	912
Hold down time to support SD-WAN service strategies	913
Adaptive Forward Error Correction	915
Dual VPN tunnel wizard	919
Duplicate packets on other zone members	920
Duplicate packets based on SD-WAN rules	923
Speed tests run from the hub to the spokes in dial-up IPsec tunnels	925
Interface based QoS on individual child tunnels based on speed test results	932
SD-WAN in large scale deployments	935
Keeping sessions in established ADVPN shortcuts while they remain in SLA	946
SD-WAN multi-PoP multi-hub large scale design and failover NEW	952
Using a single IKE elector in ADVPN to match all SD-WAN control plane traffic	971
SD-WAN Overlay-as-a-Service NEW	978
Advanced configuration	980
SD-WAN with FGCP HA	981
Configuring SD-WAN in an HA cluster using internal hardware switches	987
SD-WAN configuration portability	991
SD-WAN segmentation over a single overlay	997
Matching BGP extended community route targets in route maps	1012
Copying the DSCP value from the session original direction to its reply direction	1017
SD-WAN cloud on-ramp	1020
Configuring the VPN overlay between the HQ FortiGate and cloud FortiGate-VM	1021
Configuring the VPN overlay between the HQ FortiGate and AWS native VPN gateway	1026
Configuring the VIP to access the remote servers	1029
Configuring the SD-WAN to steer traffic between the overlays	1032
Verifying the traffic	1036
Troubleshooting SD-WAN	1042
Tracking SD-WAN sessions	1043
Understanding SD-WAN related logs	1043
SD-WAN related diagnose commands	1046
SD-WAN bandwidth monitoring service	1050
Using SNMP to monitor health check	1053
Zero Trust Network Access	1057
Zero Trust Network Access introduction	1057
ZTNA application gateway and IP/MAC based access control	1057
ZTNA telemetry, tags, and policy enforcement	1058
Application gateway	1058
Basic ZTNA configuration components	1059
Basic ZTNA configuration	1059
Establish device identity and trust context with FortiClient EMS	1071
ZTNA scalability support for concurrent endpoints	1076
SSL certificate based authentication	1078
Full versus simple ZTNA policies	1080
ZTNA advanced configurations	1087

Access control of unmanageable and unknown devices	1087
HTTP2 connection coalescing and concurrent multiplexing for ZTNA	1094
Mapping ZTNA virtual host and TCP forwarding domains to the DNS database	1096
ZTNA configuration examples	1101
ZTNA HTTPS access proxy example	1102
ZTNA HTTPS access proxy with basic authentication example	1112
ZTNA TCP forwarding access proxy example	1119
ZTNA SSH access proxy example	1125
ZTNA application gateway with SAML authentication example	1132
ZTNA application gateway with SAML and MFA using FortiAuthenticator example ..	1136
ZTNA IP MAC based access control example	1152
ZTNA IPv6 examples	1159
ZTNA Zero Trust application gateway example	1165
ZTNA troubleshooting and debugging commands	1166
Troubleshooting usage and output	1167
ZTNA troubleshooting scenarios	1171
ZTNA access control	1171
IP/MAC based access control	1172
Other useful CLI commands	1175
Policy and Objects	1176
Policies	1176
Firewall policy	1177
NGFW policy	1192
Local-in policy	1208
DoS policy	1212
Access control lists	1219
Interface policies	1220
Source NAT	1221
Destination NAT	1239
Examples and policy actions	1263
Address objects	1302
Address Types	1303
Address Group	1304
Subnet	1305
Dynamic policy — Fabric devices	1306
IP range	1308
FQDN addresses	1308
Using wildcard FQDN addresses in firewall policies	1309
Geography based addresses	1311
IPv6 geography-based addresses	1314
Wildcard addressing	1316
Interface subnet	1317
Address group	1319
Address folders	1319
Allow empty address groups	1321
Address group exclusions	1321
FSSO dynamic address subtype	1322
ClearPass integration for dynamic address objects	1326

FortiNAC tag dynamic address	1329
FortiVoice tag dynamic address NEW	1332
MAC addressed-based policies	1333
ISDB well-known MAC address list	1335
IPv6 MAC addresses and usage in firewall policies	1337
Protocol options	1339
Log oversized files	1339
RPC over HTTP	1339
Protocol port mapping	1339
Common options	1339
Web options	1340
Email options	1341
Traffic shaping	1341
Configuration methods	1342
Traffic shaping policy	1343
Traffic shaping policies	1344
Traffic shaping profiles	1353
Traffic shapers	1363
Global traffic prioritization	1378
DSCP matching and DSCP marking	1381
Examples	1385
Internet Services	1402
Using Internet Service in a policy	1403
Using custom Internet Service in policy	1407
Using extension Internet Service in policy	1408
Global IP address information database	1411
IP reputation filtering	1413
Internet service groups in policies	1414
Allow creation of ISDB objects with regional information	1418
Internet service customization	1420
Look up IP address information from the Internet Service Database page	1421
Internet Service Database on-demand mode	1422
Security Profiles	1425
Inspection modes	1425
Flow mode inspection (default mode)	1426
Proxy mode inspection	1426
Inspection mode feature comparison	1428
Antivirus	1432
Protocol comparison between antivirus inspection modes	1433
Other antivirus differences between inspection modes	1433
AI-based malware detection	1434
Configuring an antivirus profile	1434
Proxy mode stream-based scanning	1437
Databases	1441
Content disarm and reconstruction	1442
FortiGuard outbreak prevention	1444
External malware block list	1446
Malware threat feed from EMS	1449

Checking flow antivirus statistics	1451
CIFS support	1453
Using FortiSandbox post-transfer scanning with antivirus	1459
Using FortiSandbox inline scanning with antivirus	1461
Using FortiNDR inline scanning with antivirus	1471
Exempt list for files based on individual hash	1474
Downloading quarantined files in archive format NEW	1475
Web filter	1476
URL filter	1477
FortiGuard filter	1482
Credential phishing prevention	1490
Additional antiphishing settings	1492
Usage quota	1495
Web content filter	1498
Advanced filters 1	1501
Advanced filters 2	1504
Web filter statistics	1508
URL certificate blocklist	1509
Websense Integrated Services Protocol	1509
Inspecting HTTP3 traffic	1510
Configuring web filter profiles with Hebrew domain names	1512
Video filter	1517
Configuring a video filter profile	1517
Filtering based on FortiGuard categories	1517
Filtering based on YouTube channel	1522
Replacement messages displayed in blocked videos	1527
DNS filter	1529
DNS filter behavior in proxy mode	1530
FortiGuard DNS rating service	1530
Configuring a DNS filter profile	1531
FortiGuard category-based DNS domain filtering	1535
Botnet C&C domain blocking	1538
DNS safe search	1541
Local domain filter	1543
DNS translation	1548
Applying DNS filter to FortiGate DNS server	1551
DNS inspection with DoT and DoH	1552
Troubleshooting for DNS filter	1555
Application control	1558
Configuring an application sensor	1559
Basic category filters and overrides	1560
Excluding signatures in application control profiles	1563
Port enforcement check	1565
Protocol enforcement	1565
SSL-based application detection over decrypted traffic in a sandwich topology	1567
Matching multiple parameters on application control signatures	1568
Application signature dissector for DNP3	1571
Blocking QUIC manually	1571
Inline CASB NEW	1573

Example 1: privilege control	1574
Example 2: safe search	1577
Example 3: tenant control	1579
Example 4: UTM bypass	1582
Example 5: customized SaaS application and user activity	1585
Intrusion prevention	1589
Signature-based defense	1591
Configuring an IPS sensor	1594
IPS configuration options	1597
IPS signature filter options	1602
IPS with botnet C&C IP blocking	1606
IPS signatures for the operational technology security service	1610
IPS sensor for IEC 61850 MMS protocol	1611
SCTP filtering capabilities	1613
File filter	1615
Configuring a file filter profile	1617
Supported file types	1621
Email filter	1623
Protocol comparison between email filter inspection modes	1624
Configuring an email filter profile	1624
Local-based filters	1625
FortiGuard-based filters	1632
Third-party-based filters	1634
Filtering order	1635
Protocols and actions	1636
Configuring webmail filtering	1638
VoIP solutions	1638
General use cases	1639
NAT46 and NAT64 for SIP ALG	1643
SIP message inspection and filtering	1651
SIP ALG and SIP session helper	1656
SIP pinholes	1661
SIP over TLS	1663
Voice VLAN auto-assignment	1665
Scanning MSRP traffic	1666
ICAP	1670
ICAP configuration example	1671
ICAP response filtering	1673
Secure ICAP clients	1675
ICAP scanning with SCP and FTP	1676
Web application firewall	1679
Protecting a server running web applications	1680
Data leak prevention	1681
Protocol comparison between DLP inspection modes	1682
Archiving	1682
Logging and blocking files by file name	1683
Basic DLP settings	1683
Advanced DLP configurations	1686

DLP examples	1688
DLP fingerprinting	1702
FortiGuard DLP service	1706
Virtual patching NEW	1710
Example 1: basic configuration	1711
Example 2: NAC policy	1715
OT and IoT virtual patching on NAC policies	1717
SSL & SSH Inspection	1720
Configuring an SSL/SSH inspection profile	1720
Certificate inspection	1723
Deep inspection	1724
Protecting an SSL server	1727
Handling SSL offloaded traffic from an external decryption device	1728
SSH traffic file scanning	1730
Redirect to WAD after handshake completion	1732
HTTP/2 support in proxy mode SSL inspection	1733
Define multiple certificates in an SSL profile in replace mode	1734
Disabling the FortiGuard IP address rating	1736
Custom signatures	1737
Configuring custom signatures	1737
Blocking applications with custom signatures	1739
Filters for application control groups	1741
Application groups in traffic shaping policies	1744
Overrides	1748
Web rating override	1748
Using local and remote categories	1756
Web profile override	1758
Profile groups	1762
VPN	1765
IPsec VPNs	1765
General IPsec VPN configuration	1765
Site-to-site VPN	1794
Remote access	1847
Aggregate and redundant VPN	1890
ADVPN	1933
Fabric Overlay Orchestrator	1967
Other VPN topics	1987
VPN IPsec troubleshooting	2036
SSL VPN	2044
SSL VPN best practices	2044
SSL VPN quick start	2047
SSL VPN tunnel mode	2054
SSL VPN web mode	2064
SSL VPN authentication	2084
SSL VPN to IPsec VPN	2169
SSL VPN protocols	2175
Configuring OS and host check	2180
FortiGate as SSL VPN Client	2186

Dual stack IPv4 and IPv6 support for SSL VPN	2195
Disable the clipboard in SSL VPN web mode RDP connections	2206
SSL VPN IP address assignments	2211
Using SSL VPN interfaces in zones	2213
SSL VPN troubleshooting	2216
User & Authentication	2220
Endpoint control and compliance	2221
Per-policy disclaimer messages	2221
Compliance	2223
FortiGuard distribution of updated Apple certificates	2225
Integrate user information from EMS and Exchange connectors in the user store	2226
User definition and groups	2229
Users	2229
User groups	2231
Retail environment guest access	2238
User and user group timeouts	2241
LDAP servers	2242
Configuring an LDAP server	2242
Enabling Active Directory recursive search	2245
Configuring LDAP dial-in using a member attribute	2246
Configuring wildcard admin accounts	2247
Configuring least privileges for LDAP admin account authentication in Active Directory	2249
Tracking users in each Active Directory LDAP group	2250
Tracking rolling historical records of LDAP user logins	2253
Configuring client certificate authentication on the LDAP server	2256
RADIUS servers	2258
Configuring a RADIUS server	2259
Using multiple RADIUS servers	2261
RADIUS AVPs and VSAs	2264
Restricting RADIUS user groups to match selective users on the RADIUS server	2266
Configuring RADIUS SSO authentication	2267
RSA ACE (SecurID) servers	2273
Support for Okta RADIUS attributes filter-Id and class	2277
Sending multiple RADIUS attribute values in a single RADIUS Access-Request	2279
Traffic shaping based on dynamic RADIUS VSAs	2280
RADIUS Termination-Action AVP in wired and wireless scenarios	2287
Configuring a RADSEC client	2291
TACACS+ servers	2295
SAML	2296
Outbound firewall authentication for a SAML user	2297
SSL VPN with FortiAuthenticator as a SAML IdP	2298
Using a browser as an external user-agent for SAML authentication in an SSL VPN connection	2299
SAML authentication in a proxy policy	2303
Configuring SAML SSO in the GUI	2306
Outbound firewall authentication with Azure AD as a SAML IdP	2312
Authentication settings	2323

FortiTokens	2325
FortiToken Mobile quick start	2326
FortiToken Cloud	2334
Registering hard tokens	2334
Managing FortiTokens	2336
FortiToken Mobile Push	2338
Synchronizing LDAP Active Directory users to FortiToken Cloud using the two- factor filter	2340
Enable the FortiToken Cloud free trial directly from the FortiGate	2343
Troubleshooting and diagnosis	2348
Configuring the maximum log in attempts and lockout period	2352
PKI	2352
Configuring a PKI user	2352
Using the SAN field for LDAP-integrated certificate authentication	2356
Configuring firewall authentication	2360
Creating a locally authenticated user account	2360
Creating a RADIUS-authenticated user account	2361
Creating an FSSO user group	2362
Creating a firewall user group	2364
Defining policy addresses	2364
Creating security policies	2365
FSSO	2366
FSSO polling connector agent installation	2369
FSSO using Syslog as source	2372
Configuring the FSSO timeout when the collector agent connection fails	2374
Authentication policy extensions	2376
Configuring the FortiGate to act as an 802.1X supplicant	2377
Example	2378
Include usernames in logs	2379
Install and configure FSSO Agent	2380
Configure the FortiGate	2382
Log, monitor, and report examples	2384
Wireless configuration	2388
Switch Controller	2389
System	2390
Basic system settings	2390
Advanced system settings	2390
Operating modes	2391
Administrators	2393
Local authentication	2393
Remote authentication for administrators	2394
Administrator account options	2397
REST API administrator	2399
SSO administrators	2401
FortiCloud SSO	2401
Allowing the FortiGate to override FortiCloud SSO administrator user permissions ..	2402
Password policy	2407

Public key SSH access	2409
Restricting SSH and Telnet jump host capabilities	2410
Remote administrators with TACACS VSA attributes	2411
Administrator profiles	2416
super_admin profile	2416
Creating customized profiles	2416
Displaying execute commands for custom system permissions	2417
Editing profiles	2418
Deleting profiles	2418
Firmware & Registration	2418
About firmware installations	2420
Firmware maturity levels	2420
Upgrading individual device firmware	2423
Upgrading individual device firmware by following the upgrade path (federated update)	2424
Upgrading all device firmware	2426
Upgrading all device firmware by following the upgrade path (federated update)	2428
Enabling automatic firmware updates	2431
Authorizing devices	2434
Firmware upgrade notifications	2435
Downloading a firmware image	2436
Testing a firmware version	2437
Installing firmware from system reboot	2438
Restoring from a USB drive	2440
Using controlled upgrades	2441
Downgrading individual device firmware	2441
Downloading the EOS support package for supported Fabric devices	2443
Preventing FortiGates with an expired support contract from upgrading to a major or minor firmware release	2447
Settings	2449
Default administrator password	2450
Changing the host name	2451
Setting the system time	2451
Configuring ports	2455
Setting the idle timeout time	2456
Setting the password policy	2456
Changing the view settings	2457
Setting the administrator password retries and lockout time	2457
TLS configuration	2458
Controlling return path with auxiliary session	2459
Email alerts	2463
Using configuration save mode	2467
Trusted platform module support	2468
Configuring the persistency for a banned IP list	2470
Using the default certificate for HTTPS administrative access	2471
Virtual Domains	2475
VDOM overview	2475
General configurations	2480
Backing up and restoring configurations in multi VDOM mode	2488

Inter-VDOM routing configuration example: Internet access	2491
Inter-VDOM routing configuration example: Partial-mesh VDOMs	2500
High Availability	2514
FortiGate Clustering Protocol (FGCP)	2514
FortiGate Session Life Support Protocol (FGSP)	2514
VRRP	2515

Change Log

Date	Change Description
2023-08-31	Initial release.

Getting started

This section explains how to get started with a FortiGate.

Differences between models

Not all FortiGates have the same features, particularly entry-level models (models 30 to 90). A number of features on these models are only available in the CLI.

Consult your model's QuickStart Guide, [hardware manual](#), or the [Feature / Platform Matrix](#) for further information about features that vary by model.

FortiGate models differ principally by the names used and the features available:

- Naming conventions may vary between FortiGate models. For example, on some models the hardware switch interface used for the local area network is called *lan*, while on other units it is called *internal*.
- Certain features are not available on all models. Additionally, a particular feature may be available only through the CLI on some models, while that same feature may be viewed in the GUI on other models.

If you believe your FortiGate model supports a feature that does not appear in the GUI, go to *System > Feature Visibility* and confirm that the feature is enabled. For more information, see [Feature visibility on page 2702](#).

Low encryption models

Some FortiGate models support a low encryption (LENC) license. With an LENC license, FortiGate devices are considered low encryption models and are identified by *LENC*, for example FG-100E-LENC.

LENC models cannot use or inspect high encryption protocols, such as 3DES and AES. LENC models only use 56-bit DES encryption to work with SSL VPN and IPsec VPN, and they are unable to perform SSL inspection.

For a list of FortiGate models that support an LENC license, see [FortiGate LENC Models](#).

Using the GUI

This section presents an introduction to the graphical user interface (GUI) on your FortiGate.

The following topics are included in this section:

- [Connecting using a web browser](#)
- [Menus](#)
- [Tables](#)

- [Entering values](#)
- [GUI-based global search](#)
- [Loading artifacts from a CDN on page 34](#)
- [Accessing additional support resources on page 34](#)
- [Command palette on page 35](#)
- [Recovering missing graphical components on page 37](#)

For information about using the dashboards, see [Dashboards and Monitors on page 101](#).

Connecting using a web browser

In order to connect to the GUI using a web browser, an interface must be configured to allow administrative access over HTTPS or over both HTTPS and HTTP. By default, an interface has already been set up that allows HTTPS access with the IP address 192.168.1.99.

Browse to <https://192.168.1.99> and enter your username and password. If you have not changed the admin account's password, use the default user name, `admin`, and leave the password field blank.

The GUI will now display in your browser, and you will be required to provide a password for the administrator account.

To use a different interface to access the GUI:

1. Go to *Network > Interfaces* and edit the interface you wish to use for access. Take note of its assigned IP address.
2. In *Administrative Access*, select *HTTPS*, and any other protocol you require. You can also select *HTTP*, although this is not recommended as the connection will be less secure.
3. Click *OK*.
4. Browse to the IP address using your chosen protocol.
The GUI will now be displayed in your browser.

Menus

If you believe your FortiGate model supports a menu that does not appear in the GUI, go to *System > Feature Visibility* and ensure the feature is enabled. For more information, see [Feature visibility on page 2702](#).

The GUI contains the following main menus, which provide access to configuration options for most FortiOS features:

Dashboard	The dashboard displays various widgets and monitors that display important system information and allow you to configure some system options. For more information, see Dashboards and Monitors on page 101 .
Network	Options for networking, including configuring system interfaces and routing options. For more information, see Network on page 161 .
Policy & Objects	Configure firewall policies, protocol options, and supporting content for policies, including schedules, firewall addresses, and traffic shapers. For more information, see Policy and Objects on page 1176 .

Security Profiles	Configure your FortiGate's security features, including Antivirus, Web Filter, and Application Control. For more information, see Security Profiles on page 1425 .
VPN	Configure options for IPsec and SSL virtual private networks (VPNs). For more information, see IPsec VPNs on page 1765 and SSL VPN on page 2044 .
User & Authentication	Configure user accounts, groups, and authentication methods, including external authentication and single sign-on (SSO).
WiFi & Switch Controller	Configure the unit to act as a wireless network controller, managing the wireless Access Point (AP) functionality of FortiWiFi and FortiAP units. On certain FortiGate models, this menu has additional features allowing for FortiSwitch units to be managed by the FortiGate. For more information, see Wireless configuration on page 2388 and Switch Controller on page 2389 .
System	Configure system settings, such as administrators, HA, FortiGuard, and certificates. For more information, see System on page 2390 .
Security Fabric	Access the physical topology, logical topology, automation, and settings of the Fortinet Security Fabric. For more information, see Fortinet Security Fabric on page 2765 .
Log & Report	Configure logging and alert email as well as reports. For more information, see Log and Report on page 3149 .

Tables

Many GUI pages contain tables of information that can be filtered and customized to display specific information in a specific way. Some tables allow content to be edited directly on that table, or rows to be copied and pasted.

Filters

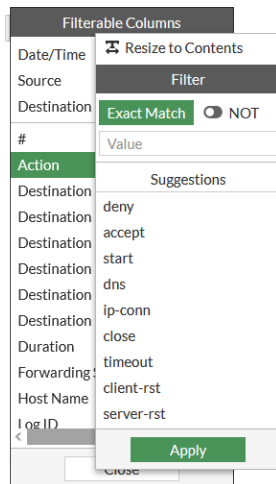

Filters are used to locate a specific set of information or content in a table. They can be particularly useful for locating specific log entries. The filtering options vary, depending on the type of information in the log.

Depending on the table content, filters can be applied using the filter bar, using a column filter, or based on a cell's content. Some tables allow filtering based on regular expressions.

Administrators with read and write access can define filters. Multiple filters can be applied at one time.

To manually create a filter:

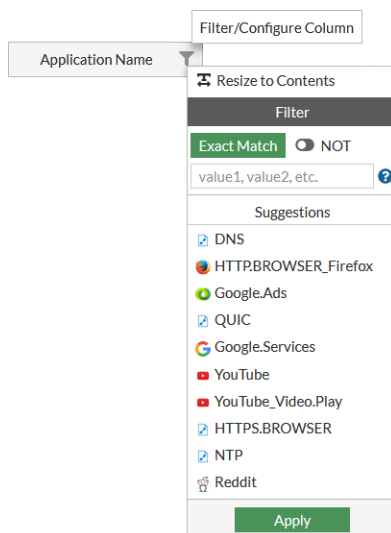

1. Click the add filter button, , in the table search bar. A list of the fields available for filtering is shown.
2. Select the field to filter by.
3. Enter the value to filter by, adding modifiers as needed.

4. Click *Apply*.

To create a column filter:

1. Click the filter icon on the right side of the column header.

2. Choose a filter type from the available options.
3. Enter the filter text, or select from the available values.
4. Click *Apply*.

To create a filter based on a cell's content:

1. Right click on a cell in the table.
2. Select *Filter by [column name]* and configure a filtering option from the menu.

Application Name		Source
HTTP.BROWSER_Firefox		1.1.1.2
HTTP.BROWSER_Firefox	1.1.1.2	
DNS		1.1.1.2
DNS		1.1.1.2

Filter by Application Name

Contains

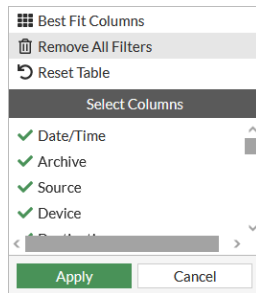

HTTP.BROWSER_Firefox

Does not contain

HTTP.BROWSER_Firefox

To remove all filters:

1. Right a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Select *Remove All Filters*.

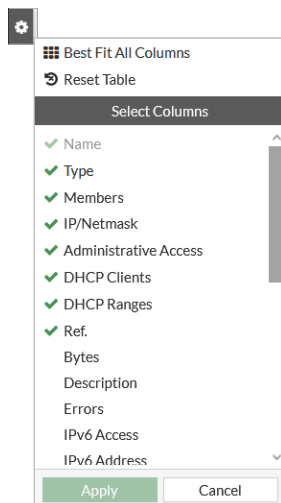

Column settings

Columns can be rearranged, resized, and added or removed from tables.

To add or remove columns:

1. Right a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.

2. Select columns to add or remove.
3. Click *Apply*.

To rearrange the columns in a table:

1. Click and drag the column header.

To resize a column:

1. Click and drag the right border of the column header.

To resize a column to fit its contents:

1. Click the dots or filter icon on the right side of the column header and select *Resize to Contents*.

**To resize all of the columns in a table to fit their content:**

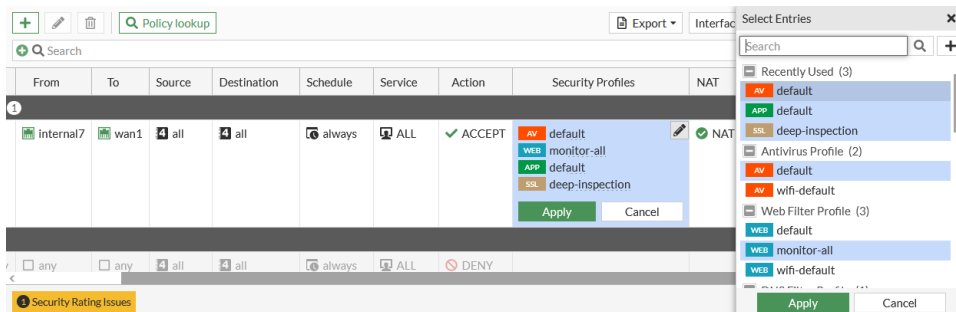

1. Right a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Click *Best Fit All Columns*.

To reset a table to its default view:

1. Right a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Click *Reset Table*.

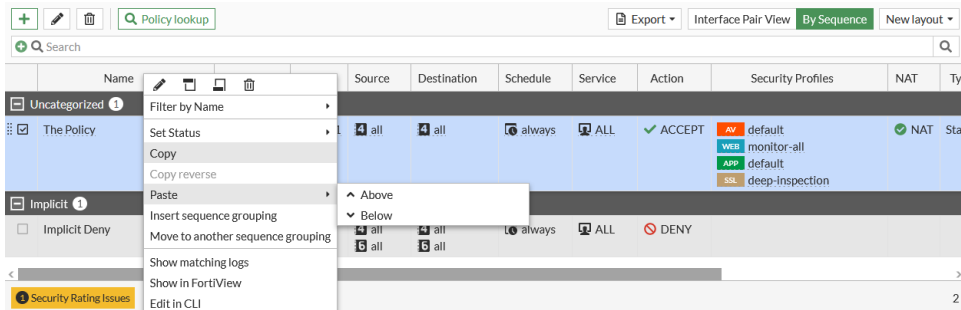

Editing objects

In some tables, parts of a configuration can be edited directly in the table. For example, security profiles can be added to an existing firewall policy by clicking the edit icon in a cell in the *Security Profiles* column.

Copying rows

In some tables, rows can be copied and pasted using the right-click menu. For example, a policy can be duplicated by copying and pasting it.

Entering values

Numerous fields in the GUI and CLI require text strings or numbers to be entered when configuring the FortiGate. When entering values in the GUI, you will be prevented from entering invalid characters, and a warning message will be shown explaining what values are not allowed. If invalid values are entered in a CLI command, the setting will be rejected when you apply it.

- [Text strings on page 31](#)
- [Numbers on page 32](#)

Text strings

Text strings are used to name entities in the FortiGate configuration. For example, the name of a firewall address, administrator, or interface are all text strings.

The following characters cannot be used in text strings, as they present cross-site scripting (XSS) vulnerabilities:

- " - double quotes
- ' - single quote
- > - greater than
- < - less than

Most GUI text fields prevent XSS vulnerable characters from being added.

VDOM names and hostnames can only use numbers (0-9), letters (a-z and A-Z), dashes, and underscores.

The `tree` CLI command can be used to view the number of characters allowed in a name field. For example, entering the following commands show that a firewall address name can contain up to 79 characters, while its FQDN can contain 255 characters:

```
# tree firewall address
-- [address] --*name      (79)
    |- uuid
    |- subnet
    |- type
    |- route-tag          (0,4294967295)
    |- sub-type
    |- clearpass-spt
```

```

|- [macaddr] --*macaddr      (127)
|- start-ip
|- end-ip
|- fqdn      (255)
|- country   (2)
|- wildcard-fqdn (255)
|- cache-ttl  (0,86400)
|- wildcard
|- sdn        (35)
|- [fsso-group] --*name      (511)
|- interface  (35)
|- tenant     (35)
|- organization (35)
|- epd-name    (255)
|- subnet-name (255)
|- sdn-tag     (15)
|- policy-group (15)
|- obj-tag     (255)
|- obj-type
|- tag-detection-level (15)
|- tag-type    (63)
|- dirty
|- hw-vendor   (35)
|- hw-model    (35)
|- os          (35)
|- sw-version  (35)
|- comment
|- associated-interface (35)
|- color      (0,32)
|- filter
|- sdn-addr-type
|- node-ip-only
|- obj-id
|- [list] --*ip      (35)
      |- obj-id      (127)
      +- net-id      (127)
|- [tagging] --*name  (63)
      |- category    (63)
      +- [tags] --*name (79)
|- allow-routing
+- fabric-object

```

Numbers

Numbers are used to set sizes, rates, addresses, port numbers, priorities, and other such numeric values. They can be entered as a series of digits (without commas or spaces), in a dotted decimal format (such as IP addresses), or separated by colons (such as MAC addresses). Most numeric values use base 10 numbers, while some use hexadecimal values.

Most GUI and CLI fields prevent invalid numbers from being entered. The CLI help text includes information about the range of values allowed for applicable settings.

GUI-based global search

The global search option in the GUI allows users to search for keywords appearing in objects and navigation menus to quickly access the object and configuration page. Click the magnifying glass icon in the top-left corner of the banner to access the global search.

The global search includes the following features:

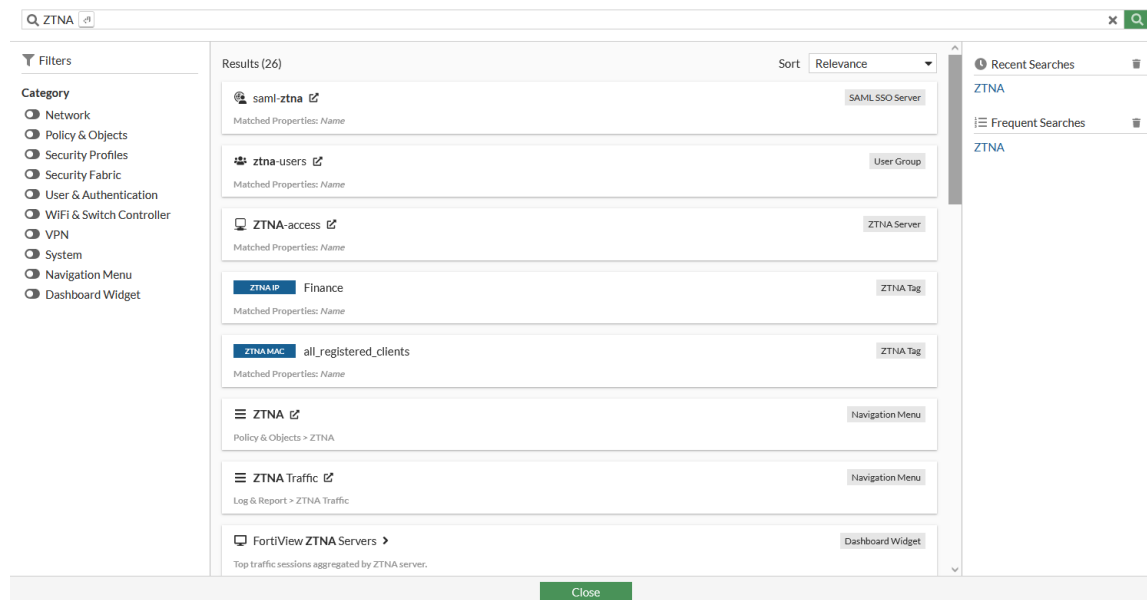

- Keep a history of frequent and recent searches
- Sort results by relevance (by search weight), or alphabetically in increasing or decreasing order
- Search by category
- Search in Security Fabric members (accessed by the Security Fabric members dropdown menu in the banner)
- Search for dashboard widgets and monitors, and preview the widget or go directly to the monitor dashboard if it exists.

Examples

In this example, searching for the word *ZTNA* yields the following results:

- A ZTNA server, user group, and SAML SSO server that have the *ZTNA* in the *Name* field.
- Various ZTNA tag.
- ZTNA navigation tree items: *Policy & Objects > ZTNA* and *Log & Report > ZTNA Traffic*.
- The FortiView ZTNA Servers dashboard widget.

CMDB objects have a higher search weight (50) than navigation objects (20), so the navigation menus and widgets appears at the bottom of the results when sorting by relevance.

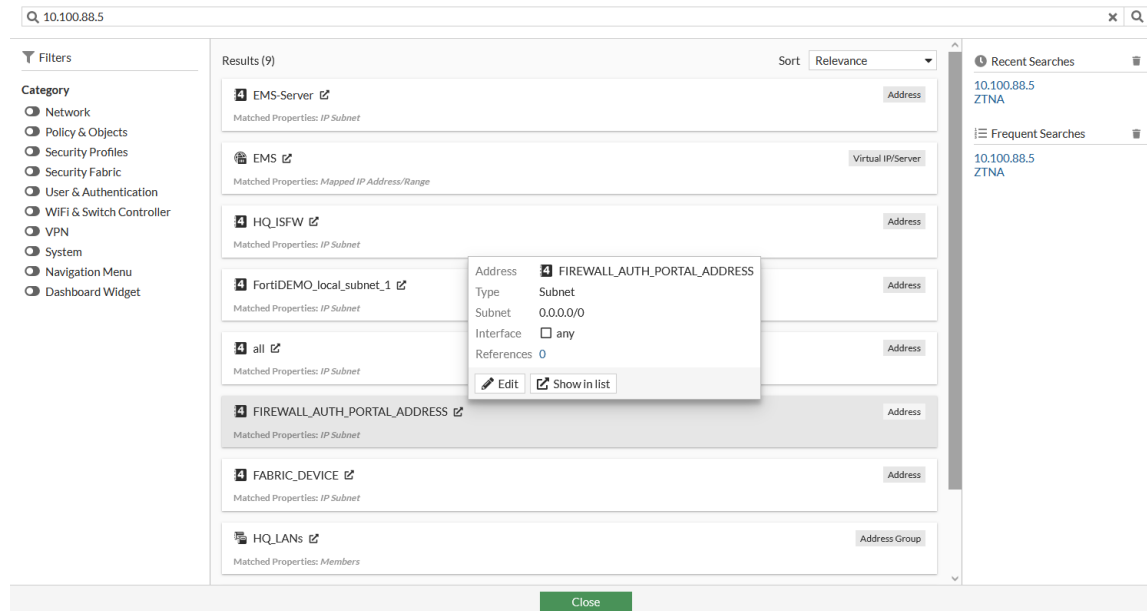

In this example, searching for the address *10.100.88.5* yields the following results:

- Various address objects that have a subnet of 10.100.88.5.
- A Virtual IP/Server object, *EMS*, that has a mapped IP address/range with 10.100.88.5.

- Address objects that have IP subnets of 0.0.0.0/0, which the search term falls into.
- Address group objects that contains members addresses that have IP subnets of 0.0.0.0/0.

Sorting by *Relevance* displays address objects that are more closely matched at the top (10.100.88.5), and more loosely matched at the bottom (0.0.0.0).

Loading artifacts from a CDN

To improve GUI performance, loading static GUI artifacts cached in CDN (content delivery network) servers closer to the user instead of the FortiGate can be enabled. This allows the GUI to load more quickly with less latency for administrators who are accessing the FortiGate remotely. Upon failure, the files fall back to loading from the FortiGate. The CDN is only used after successful administrator logins.

To configure loading static GUI files from a CDN:

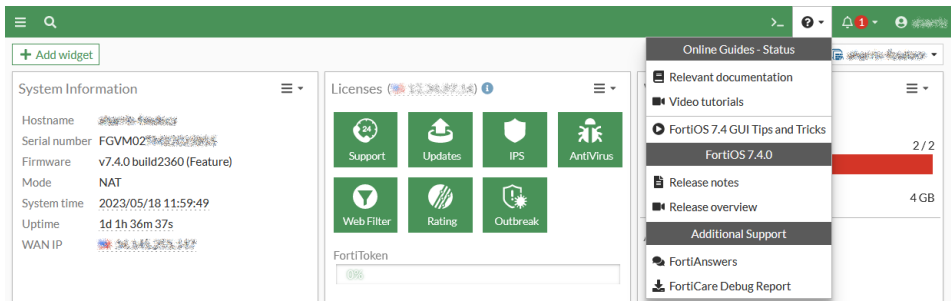

```
config system global
    set gui-cdn-usage {enable | disable}
end
```

Accessing additional support resources

Additional support resources can be accessed from the GUI to troubleshoot issues and get the most out of FortiOS. Online guides, FortiOS documentation, and additional support can now be accessed straight from the help menu.

To access support resources:

1. Click *Help* in the top menu. A dropdown menu is displayed.

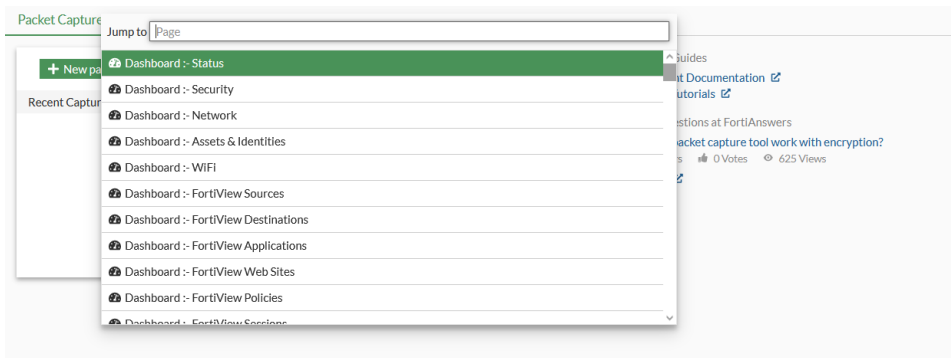

2. Select the support resource you are looking for:
 - *Online Guides* lists resources for help documentation and videos.
 - *FortiOS <version>* contains release information.
 - *Additional Support* contains a link to download the *FortiCare Debug Report*.

Command palette

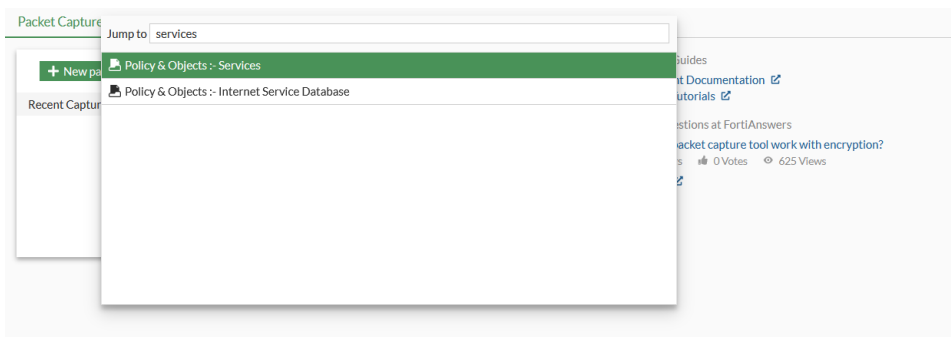

The command palette is a keyboard shortcut menu that can be used to quickly navigate to GUI pages or run specific actions, such as opening the CLI console or restoring a system configuration.

To navigate to a new GUI page using the command palette:

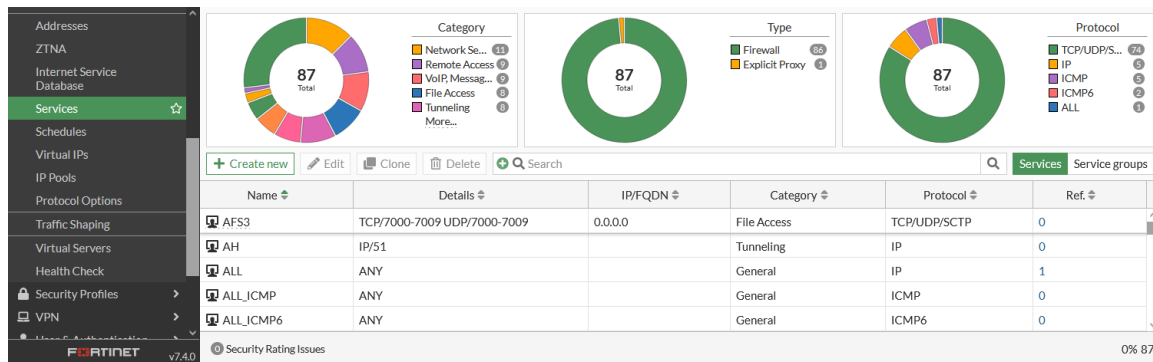

1. Press `ctrl+p` (or `cmd+p` for Mac). The command palette is displayed with available navigation links.

2. Enter the required destination.

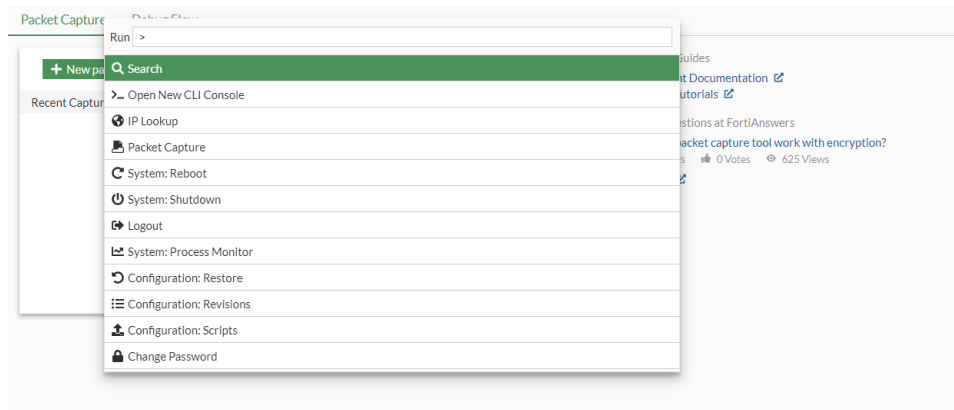

3. Press *Enter* to jump to the select GUI page.

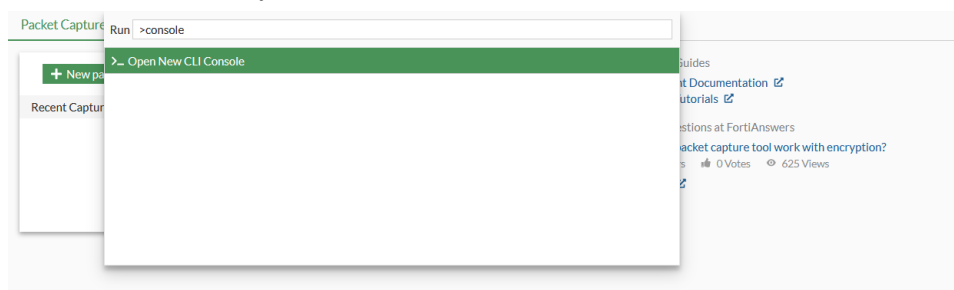

To activate an action using the command palette:

1. Press `ctrl+p` (or `cmd+p` for Mac) and then enter `a >`. On supported browsers, `ctrl+shift+p` (or `cmd+shift+p` for Mac) can be used.

The command palette is displayed with a runnable command list.

2. Enter the command key word.

3. Press `Enter` to run the action.

Recovering missing graphical components

Errors can sometimes cause the application icons, or other minor graphical components, to no longer show up in the GUI.

For example, in the *FortiView Applications* monitor, the icons could be missing from the *Application* column.

FortiView Applications by Bytes

FortiGate Cloud 7 days

Drill down Search filterable columns

Application	Category	Risk	Bytes	Sessions

Using the CLI

The Command Line Interface (CLI) can be used in lieu of the GUI to configure the FortiGate. Some settings are not available in the GUI, and can only be accessed using the CLI.

This section briefly explains basic CLI usage. For information about the CLI config commands, see the [FortiOS CLI Reference](#).

- [Connecting to the CLI on page 39](#)
- [CLI basics on page 42](#)
- [Command syntax on page 48](#)
- [Subcommands on page 50](#)
- [Permissions on page 53](#)

Connecting to the CLI

You can connect to the CLI using a direct console connection, SSH, the FortiExplorer app, or the CLI console in the GUI.

You can access the CLI outside of the GUI in three ways:

- **Console connection:** Connect your computer directly to the console port of your FortiGate.
- **SSH access:** Connect your computer through any network interface attached to one of the network ports on your FortiGate.
- **FortiExplorer:** Connect your device to the FortiExplorer app on your device to configure, manage, and monitor your FortiGate. See [FortiExplorer management on page 53](#) for details.

To open a CLI console, click the `_>` icon in the top right corner of the GUI. The console opens on top of the GUI. It can be minimized and multiple consoles can be opened. On many GUI pages, the CLI console can be opened with that pages specific commands already shown by clicking *Edit in CLI* in the right-side gutter.

To edit policies and objects directly in the CLI, right-click on the element and select *Edit in CLI*.

Console connection

A direct console connection to the CLI is created by directly connecting your management computer or console to the FortiGate using its DB-9 or RJ-45 console port.

Direct console access to the FortiGate may be required if:

- You are installing the FortiGate for the first time and it is not configured to connect to your network.
- You are restoring the firmware using a boot interrupt. Network access to the CLI will not be available until after the boot process has completed, making direct console access the only option.

To connect to the FortiGate console, you need:

- A console cable to connect the console port on the FortiGate to a communications port on the computer. Depending on your device, this is one of:
 - null modem cable (DB-9 to DB-9)
 - DB-9 to RJ-45 cable (a DB-9-to-USB adapter can be used)
 - USB to RJ-45 cable
- A computer with an available communications port
- Terminal emulation software

To connect to the CLI using a direct console connection:

1. Using the console cable, connect the FortiGate unit's console port to the serial communications (COM) port on your management computer.
2. Start a terminal emulation program on the management computer, select the COM port, and use the following settings:

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

3. Press *Enter* on the keyboard to connect to the CLI.
4. Log in to the CLI using your username and password (default: *admin* and no password).
You can now enter CLI commands, including configuring access to the CLI through SSH.

SSH access

SSH access to the CLI is accomplished by connecting your computer to the FortiGate using one of its network ports. You can either connect directly, using a peer connection between the two, or through any intermediary network.

If you do not want to use an SSH client and you have access to the GUI, you can access the CLI through the network using the CLI console in the GUI.

SSH must be enabled on the network interface that is associated with the physical network port that is used.

If your computer is not connected either directly or through a switch to the FortiGate, you must also configure the FortiGate with a static route to a router that can forward packets from the FortiGate to the computer. This can be done using a local console connection, or in the GUI.

To connect to the FortiGate CLI using SSH, you need:

- A computer with an available serial communications (COM) port and RJ-45 port
- An appropriate console cable
- Terminal emulation software
- A network cable
- Prior configuration of the operating mode, network interface, and static route.

To enable SSH access to the CLI using a local console connection:

1. Using the network cable, connect the FortiGate unit's port either directly to your computer's network port, or to a network through which your computer can reach the FortiGate.
2. Note the number of the physical network port.
3. Using direct console connection, connect and log into the CLI.

4. Enter the following command:

```
config system interface
    edit <interface_str>
        append allowaccess ssh
    next
end
```

Where `<interface_str>` is the name of the network interface associated with the physical network port, such as `port1`.

5. Confirm the configuration using the following command to show the interface's settings:

```
show system interface <interface_str>
```

For example:

```
show system interface port1
config system interface
    edit "port1"
        set vdom "root"
        set ip 192.168.1.99 255.255.255.0
        set allowaccess ping https ssh
        set type hard-switch
        set stp enable
        set role lan
        set snmp-index 6
    next
end
```

Connecting using SSH

Once the FortiGate is configured to accept SSH connections, use an SSH client on your management computer to connect to the CLI.

The following instructions use [PuTTY](#). The steps may vary in other terminal emulators.

To connect to the CLI using SSH:

1. On your management computer, start PuTTY.
2. In the *Host Name (or IP address)* field, enter the IP address of the network interface that you are connected to and that has SSH access enabled.
3. Set the port number to 22, if it is not set automatically.
4. Select **SSH** for the *Connection type*.
5. Click **Open**. The SSH client connects to the FortiGate.
The SSH client may display a warning if this is the first time that you are connecting to the FortiGate and its SSH key is not yet recognized by the SSH client, or if you previously connected to the FortiGate using a different IP address or SSH key. This is normal if the management computer is connected directly to the FortiGate with no network hosts in between.
6. Click **Yes** to accept the FortiGate's SSH key.
The CLI displays the log in prompt.
7. Enter a valid administrator account name, such as `admin`, then press **Enter**.
8. Enter the administrator account password, then press **Enter**.
The CLI console shows the command prompt (FortiGate hostname followed by a `#`). You can now enter CLI commands.

If three incorrect log in or password attempts occur in a row, you will be disconnected. If this occurs, wait for one minute, then reconnect and attempt to log in again.

CLI basics

Basic features and characteristics of the CLI environment provide support and ease of use for many CLI tasks.

Help

Press the question mark (?) key to display command help and complete commands.

- Press the question mark (?) key at the command prompt to display a list of the commands available and a description of each command.
- Enter a command followed by a space and press the question mark (?) key to display a list of the options available for that command and a description of each option.
- Enter a command followed by an option and press the question mark (?) key to display a list of additional options available for that command option combination and a description of each option.
- Enter a question mark after entering a portion of a command to see a list of valid complete commands and their descriptions. If there is only one valid command, it will be automatically filled in.

Shortcuts and key commands

Shortcut key	Action
?	List valid complete or subsequent commands. If multiple commands can complete the command, they are listed with their descriptions.
Tab	Complete the word with the next available match. Press multiple times to cycle through available matches.
Up arrow or Ctrl + P	Recall the previous command. Command memory is limited to the current session.
Down arrow, or Ctrl + N	Recall the next command.
Left or Right arrow	Move the cursor left or right within the command line.
Ctrl + A	Move the cursor to the beginning of the command line.
Ctrl + E	Move the cursor to the end of the command line.
Ctrl + B	Move the cursor backwards one word.
Ctrl + F	Move the cursor forwards one word.
Ctrl + D	Delete the current character.
Ctrl + C	Abort current interactive commands, such as when entering multiple lines.

Shortcut key	Action
	If you are not currently within an interactive command such as <code>config</code> or <code>edit</code> , this closes the CLI connection.
\ then Enter	Continue typing a command on the next line for a multiline command. For each line that you want to continue, terminate it with a backslash (<code>\</code>). To complete the command, enter a space instead of a backslash, and then press <i>Enter</i> .

Command tree

Enter `tree` to display the CLI command tree. To capture the full output, connect to your device using a terminal emulation program and capture the output to a log file. For some commands, use the `tree` command to view all available variables and subcommands.

Command abbreviation

You can abbreviate words in the command line to their smallest number of non-ambiguous characters.

For example, the command `get system status` could be abbreviated to `g sy stat`.

Adding and removing options from lists

When configuring a list, the `set` command will remove the previous configuration.

For example, if a user group currently includes members A, B, and C, the command `set member D` will remove members A, B, and C. To avoid removing the existing members from the group, the command `set members A B C D` must be used.

To avoid this issue, the following commands are available:

append	Add an option to an existing list. For example, <code>append member D</code> adds user D to the user group without removing any of the existing members.
select	Clear all of the options except for those specified. For example, <code>select member B</code> removes all member from the group except for member B.
unselect	Remove an option from an existing list. For example, <code>unselect member C</code> removes only member C from the group, without affecting the other members.

Environment variables

The following environment variables are support by the CLI. Variable names are case-sensitive.

\$USERFROM	The management access type (<code>ssh</code> , <code>jsconsole</code> , and so on) and the IPv4 address of the administrator that configured the item.
\$USERNAME	The account name of the administrator that configured the item.
\$SerialNum	The serial number of the FortiGate.

For example, to set a FortiGate device's host name to its serial number, use the following CLI command:

```
config system global
    set hostname $SerialNum
end
```

Special characters

The following characters cannot be used in most CLI commands: `<`, `>`, `(`, `)`, `#`, `'`, and `"`

If one of those characters, or a space, needs to be entered as part of a string, it can be entered by using a special command, enclosing the entire string in quotes, or preceding it with an escape character (backslash, `\`).

To enter a question mark (`?`) or a tab, `Ctrl + V` or `Ctrl + Shift + -` (depending on the method being used to access the CLI) must be entered first.

Question marks and tabs cannot be copied into the CLI Console or some SSH clients. They must be typed in.

Character	Keys
<code>?</code>	<code>Ctrl + V</code> or <code>Ctrl + Shift + -</code> then <code>?</code>
Tab	<code>Ctrl + V</code> then Tab
Space (as part of a string value, not to end the string)	Enclose the string in single or double quotation marks: <code>"Security Administrator"</code> or <code>'Security Administrator'</code> . Precede the space with a backslash: <code>Security\ Administrator</code> .
<code>'</code> (as part of a string value, not to begin or end the string)	<code>\'</code>
<code>"</code> (as part of a string value, not to begin or end the string)	<code>\"</code>
<code>\</code>	<code>\\</code>

Using grep to filter command output

The `get`, `show`, and `diagnose` commands can produce large amounts of output. The `grep` command can be used to filter the output so that it only shows the required information.

The `grep` command is based on the standard UNIX `grep`, used for searching text output based on regular expressions.

For example, the following command displays the MAC address of the internal interface:

```
get hardware nic internal | grep Current_HWaddr
Current_HWaddr          00:09:0f:cb:c2:75
```

The following command will display all TCP sessions that are in the session list, including the session list line number in the output:

```
get system session list | grep -n tcp
```

The following command will display all of the lines in the HTTP replacement message that contain URL or url:

```
show system replacemsg http | grep -i url
```

The following options can also be used:

```
-A <num> After
-B <num> Before
-C <num> Context
```

The `-f` option is available to support contextual output, in order to show the complete configuration. The following example shows the difference in the output when `-f` is used versus when it is not used:

Without `-f`:

```
show | grep ldap-group1
edit "ldap-group1"
    set groups "ldap-group1"
```

With `-f`:

```
show | grep -f ldap-group1
config user group
    edit "ldap-group1"
        set member "pc40-LDAP"
    next
end
config firewall policy
    edit 2
        set srcintf "port31"
        set dstintf "port32"
        set srcaddr "all"
        set action accept
        set identity-based enable
        set nat enable
        config identity-based-policy
            edit 1
                set schedule "always"
                set groups "ldap-group1"
                set dstaddr "all"
                set service "ALL"
            next
        end
    next
end
```

Language support and regular expressions

Characters such as ñ and é, symbols, and ideographs are sometimes acceptable input. Support varies depending on the type of item that is being configured. CLI commands, objects, field names, and options must use their exact ASCII characters, but some items with arbitrary names or values can be input using your language of choice. To use other languages in those cases, the correct encoding must be used.

Input is stored using Unicode UTF-8 encoding, but is not normalized from other encodings into UTF-8 before it is stored. If your input method encodes some characters differently than in UTF-8, configured items may not display or operate as expected.

Regular expressions are especially impacted. Matching uses the UTF-8 character values. If you enter a regular expression using a different encoding, or if an HTTP client sends a request in a different encoding, matches may not be what is expected.

For example, with Shift-JIS, backslashes could be inadvertently interpreted as the symbol for the Japanese yen (¥), and vice versa. A regular expression intended to match HTTP requests containing monetary values with a yen symbol may not work if the symbol is entered using the wrong encoding.

For best results:

- use UTF-8 encoding, or
- use only characters whose numerically encoded values are the same in UTF-8, such as the US-ASCII characters that are encoded using the same values in ISO 8859-1, Windows code page 1252, Shift-JIS, and other encoding methods, or
- for regular expressions that must match HTTP requests, use the same encoding as your HTTP clients.

HTTP clients may send requests in encodings other than UTF-8. Encodings usually vary based on the client's operating system or input language. If the client's encoding method cannot be predicted, you might only be able to match the parts of the request that are in English, as the values for English characters tend to be encoded identically, regardless of the encoding method.

If the FortiGate is configured to use an encoding method other than UTF-8, the management computer's language may need to be changed, including the web browse and terminal emulator. If the FortiGate is configured using non-ASCII characters, all the systems that interact with the FortiGate must also support the same encoding method. If possible, the same encoding method should be used throughout the configuration to avoid needing to change the language settings on the management computer.

The GUI and CLI client normally interpret output as encoded using UTF-8. If they do not, configured items may not display correctly. Exceptions include items such as regular expression that may be configured using other encodings to match the encoding of HTTP requests that the FortiGate receives.

To enter non-ASCII characters in a terminal emulator:

1. On the management computer, start the terminal client.
2. Configure the client to send and receive characters using UTF-8 encoding.
Support for sending and receiving international characters varies by terminal client.
3. Log in to the FortiGate.
4. At the command prompt, type your command and press *Enter*.
Words that use encoded characters may need to be enclosed in single quotes (').

Depending on your terminal client's language support, you may need to interpret the characters into character codes before pressing *Enter*. For example, you might need to enter: `edit '\743\601\613\743\601\652'`

5. The CLI displays the command and its output.

Screen paging

By default, the CLI will pause after displaying each page worth of text when a command has multiple pages of output. This can be useful when viewing lengthy outputs that might exceed the buffer of terminal emulator.

When the display pauses and shows `--More--`, you can:

- Press *Enter* to show the next line,
- Press *Q* to stop showing results and return to the command prompt,
- Press an arrow key, *Insert*, *Home*, *Delete*, *End*, *Page Up*, or *Page Down* to show the next few pages,
- Press any other key to show the next page, or
- Wait for about 30 seconds for the console to truncate the output and return to the command prompt.

When pausing the screen is disabled, press *Ctrl + C* to stop the output and log out of the FortiGate.

To disable pausing the CLI output:

```
config system console
    set output standard
end
```

To enable pausing the CLI output:

```
config system console
    set output more
end
```

Changing the baud rate

The baud rate of the local console connection can be changed from its default value of 9600.

To change the baud rate:

```
config system console
    set baudrate {9600 | 19200 | 38400 | 57600 | 115200}
end
```

Editing the configuration file

The FortiGate configuration file can be edited on an external host by backing up the configuration, editing the configuration file, and then restoring the configuration to the FortiGate.

Editing the configuration file can save time if many changes need to be made, particularly if the plain text editor that you are using provides features such as batch changes.

To edit the configuration file:

1. Backup the configuration. See [Configuration backups on page 72](#) for details.
2. Open the configuration file in a plain text editor that supports UNIX-style line endings.
3. Edit the file as needed.

Do not edit the first line of the configuration file.

This line contains information about the firmware version and FortiGate model. If you change the model number, the FortiGate will reject the configuration when you attempt to restore it.

4. Restore the modified configuration to the FortiGate. See [Configuration backups on page 72](#) for details.
The FortiGate downloads the configuration file and checks that the model information is correct. If it is correct, the configuration file is loaded and each line is checked for errors. If a command is invalid, that command is ignored. If the configuration file is valid, the FortiGate restarts and loads the downloaded configuration.

Command syntax

When entering a command, the CLI console requires that you use valid syntax and conform to expected input constraints. It rejects invalid commands. Indentation is used to indicate the levels of nested commands.

Each command line consists of a command word, usually followed by configuration data or a specific item that the command uses or affects.

Notation

Brackets, vertical bars, and spaces are used to denote valid syntax. Constraint notations, such as `<address_ipv4>`, indicate which data types or string patterns are acceptable value input.

All syntax uses the following conventions:

Angle brackets < >	Indicate a variable of the specified data type.
Curly brackets { }	Indicate that a variable or variables are mandatory.
Square brackets []	Indicate that the variable or variables are optional. For example: <code>show system interface [<name_str>]</code> To show the settings for all interfaces, you can enter <code>show system interface</code> To show the settings for the Port1 interface, you can enter <code>show system interface port1</code> .
Vertical bar 	A vertical bar separates alternative, mutually exclusive options. For example: <code>set protocol {ftp sftp}</code> You can enter either <code>set protocol ftp</code> or <code>set protocol sftp</code> .
Space	A space separates non-mutually exclusive options. For example:

```
set allowaccess {ping https ssh snmp http fgfm radius-acct probe-
response capwap ftm}
```

You can enter any of the following:

```
set allowaccess ping
set allowaccess https ping ssh
set allowaccess http https snmp ssh ping
```

In most cases, to make changes to lists that contain options separated by spaces, you need to retype the entire list, including all the options that you want to apply and excluding all the options that you want to remove.

Optional values and ranges

Any field that is optional will use square-brackets. The overall config command will still be valid whether or not the option is configured.

Square-brackets can be used to show that multiple options can be set, even intermixed with ranges. The following example shows a field that can be set to either a specific value or range, or multiple instances:

```
config firewall service custom
    set iprange <range1> [<range2> <range3> ...]
end
```

next

The `next` command is used to maintain a hierarchy and flow to CLI commands. It is at the same indentation level as the preceding `edit` command, to mark where a table entry finishes.

The following example shows the `next` command used in the subcommand `entries`:

```
config dlp filepattern
edit <1>
    set name <name>
    set comment [comment]
    config entries
        edit <2>
            set filter-type {pattern | type}
            next
        ←
```

After configuring table entry <2> then entering `next`, the <2> table entry is saved and the console returns to the `entries` prompt:

```
FGT60E1Q23456789 (entries) #
```

You can now create more table entries as needed, or enter `end` to save the table and return to the `filepattern` table element prompt.

end

The `end` command is used to maintain a hierarchy and flow to CLI commands.

The following example shows the same command and subcommand as the `next` command example, except `end` has been entered instead of `next` after the subcommand:

```
config dlp filepattern
```

```
edit <1>
    set name <name>
    set comment [comment]
    config entries
        edit <2>
            set filter-type {pattern | type}
end
|←
```

Entering `end` will save the `<2>` table entry and the table, and exit the `entries` subcommand entirely. The console returns to the `filepattern` table element prompt:

```
FGT60E1Q23456789 (1) #
```

Subcommands

Subcommands are available from within the scope of some commands. When you enter a subcommand level, the command prompt changes to indicate the name of the current command scope. For example, after entering:

```
config system admin
```

the command prompt becomes:

```
(admin) #
```

Applicable subcommands are available until you exit the command, or descend an additional level into another subcommand. Subcommand scope is indicated by indentation.

For example, the `edit` subcommand is only available in commands that affects tables, and the `next` subcommand is available only in the `edit` subcommand:

```
config system interface
    edit port1
        set status up
    next
end
```

The available subcommands vary by command. From a command prompt under the `config` command, subcommands that affect tables and fields could be available.

Table subcommands

edit <table_row>

Create or edit a table value.

In objects such as security policies, <table_row> is a sequence number. To create a new table entry without accidentally editing an existing entry, enter `edit 0`. The CLI will confirm that creation of entry 0, but will assign the next unused number when the entry is saved after entering `end` or `next`.

For example, to create a new firewall policy, enter the following commands:

```
config firewall policy
    edit 0
        ...
    next
end
```

To edit an existing policy, enter the following commands:

```
config firewall policy
    edit 27
        ...
    next
end
```

The `edit` subcommand changes the command prompt to the name of the table value that is being edited, such as `(27) #`.

delete <table_row>

Delete a table value.

For example, to delete firewall policy 27, enter the following commands:

```
config firewall policy
    delete 27
end
```

purge

Clear all table values.

The `purge` command cannot be undone. To restore purged table values, the configuration must be restored from a backup.

move

Move an ordered table value.

In the firewall policy table, this is equivalent to dragging a policy into a new position. It does not change the policy's ID number.

For example, to move policy 27 to policy 30, enter the following commands:

```
config firewall policy
    move 27 to 30
end
```

The `move` subcommand is only available in tables where the order of the table entries matters.

clone <table_row> to <table_row>

Make a clone of a table entry.

For example, to create firewall policy 30 as a clone of policy 27, enter the following commands:

```
config firewall policy
    clone 27 to 30
end
```

The `clone` subcommand may not be available for all tables.

rename <table_row> to <table_row>

Rename a table entry.

For example to rename an administrator from Fry to Leela, enter the following commands:

```
config system admin
    rename Fry to Leela
end
```

The `rename` subcommand is only available in tables where the entries can be renamed.

get

List the current table entries.

For example, to view the existing firewall policy table entries, enter the following commands:

```
config firewall policy
    get
```

show

Show the configuration. Only table entries that are not set to default values are shown.

end

Save the configuration and exit the current `config` command.

Purging the `system interface` or `system admin` tables does not reset default table values. This can result in being unable to connect to or log in to the FortiGate, requiring the FortiGate to be formatted and restored.

Field subcommands

set <field> <value>

Modify the value of a field.

For example, the command `set fsso enable` sets the `fsso` field to the value `enable`.

unset

Set the field to its default value.

select

Clear all of the options except for those specified.

For example, if a group contains members A, B, C, and D, to remove all members except for B, use the command `select member B`.

unselect

Remove an option from an existing list.

For example, if a group contains members A, B, C, and D, to remove only member B, use the command `unselect member B`.

append

Add an option to an existing multi-option table value.

clear

Clear all the options from a multi-option table value.

get	List the configuration of the current table entry, including default and customized values.
show	Show the configuration. Only values that are not set to default values are shown.
next	Save changes to the table entry and exit the <code>edit</code> command so that you can configure the next table entry.
abort	Exit the command without saving.
end	Save the configuration and exit the current <code>config</code> command.

Permissions

Administrator (or access) profiles control what CLI commands an administrator can access by assigning read, write, or no access to each area of FortiOS. For information, see [Administrator profiles on page 2416](#).

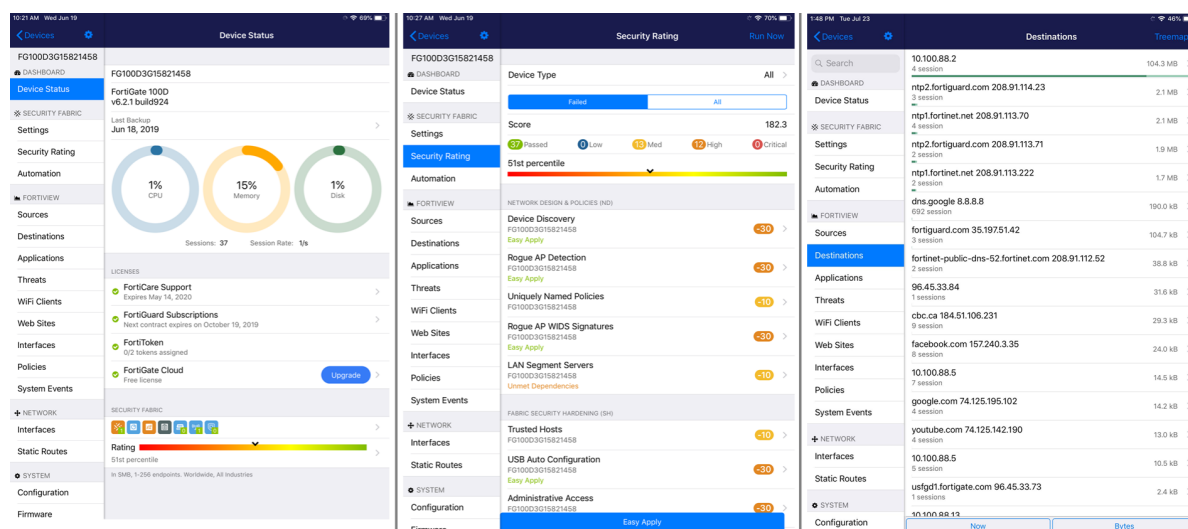

Read access is required to view configurations. Write access is required to make configuration changes. Depending on your account's profile, you may not have access to all CLI commands. To have access to all CLI commands, an administrator account with the *super_admin* profile must be used, such as the *admin* account.

Accounts assigned the *super_admin* profile are similar to the root administrator account. They have full permission to view and change all FortiGate configuration options, including viewing and changing other administrator accounts.

To increase account security, set strong passwords for all administrator accounts and change the passwords regularly. See [Default administrator password on page 2450](#) and [Password policy on page 2407](#) for more information.

FortiExplorer management

FortiExplorer for iOS is a user-friendly application that helps you to rapidly provision, deploy, and monitor Security Fabric components from your iOS device.

FortiExplorer for iOS requires iOS 10.0 or later and is compatible with iPhone, iPad, and Apple TV. It is supported by FortiOS 5.6 and later, and is available on the [App Store](#) for iOS devices.

FortiExplorer is also available for support on Android on the [Google Play Store](#). Steps for configuring FortiExplorer for Android may differ from what is included in the guide.

Advanced features are available with the purchase of FortiExplorer Pro. Paid features include the ability to add more than two devices, and firmware upgrades for devices with active licenses.

Up to six members can use this app with 'Family Sharing' enabled in the App Store.

Firmware upload requires a valid firmware license. Users can download firmware for models with a valid support contract.

Getting started with FortiExplorer

If your FortiGate is accessible on a wireless network, you can connect to it using FortiExplorer provided that your iOS device is on the same network. See [Connecting FortiExplorer to a FortiGate with WiFi](#). If your 200F series or 80F series FortiGate is in close proximity, you can connect to it using FortiExplorer using Bluetooth Low Energy (BLE). See [Configure FortiGate with FortiExplorer using BLE on page 58](#). Otherwise, you will need to physically connect your iOS device to the FortiGate using a USB cable.

To connect and configure a FortiGate with FortiExplorer using a USB connection:

1. Connect your iOS device to your FortiGate USB A port. If prompted on your iOS device, *Trust* this computer.
2. Open FortiExplorer and select your FortiGate from the *FortiGate Devices* list . A blue USB icon will indicate that you are connected over a USB connection.

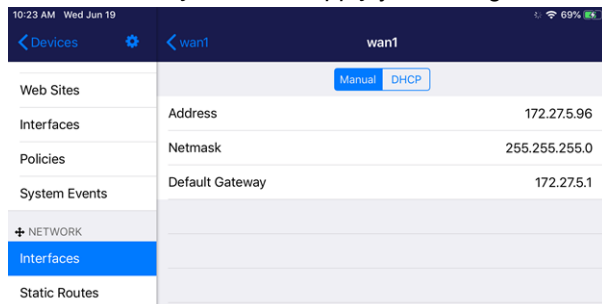

3. On the *Login* screen, select *USB*.
4. Enter the default *Username* (`admin`) and leave the *Password* field blank.
5. Optionally, select *Remember Password*.
6. Tap *Done* when you are ready.

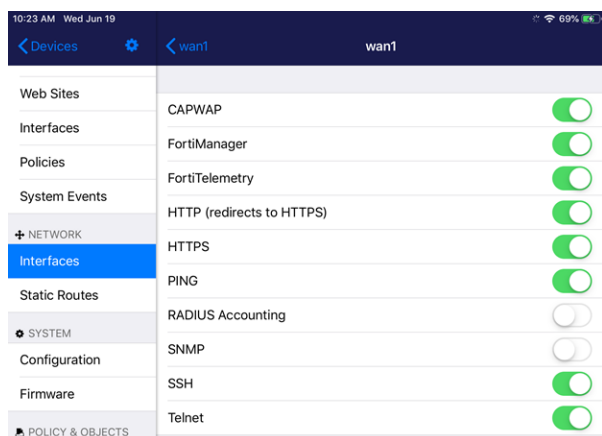

FortiExplorer opens the FortiGate management interface to the *Device Status* page:

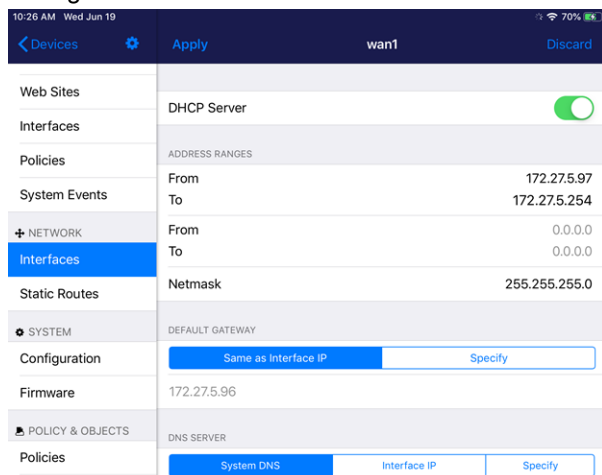

7. Go to *Network > Interfaces* and configure the WAN interface or interfaces.
8. The *wan1* interface *Address mode* is set to *DHCP* by default. Set it to *Manual* and enter its *Address*, *Netmask*, and *Default Gateway*, and then *Apply* your changes.

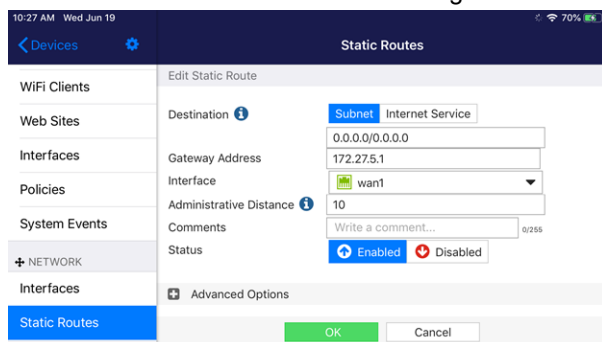

9. Optionally, configure *Administrative Access* to allow *HTTPS* access. This will allow administrators to access the FortiGate GUI using a web browser.

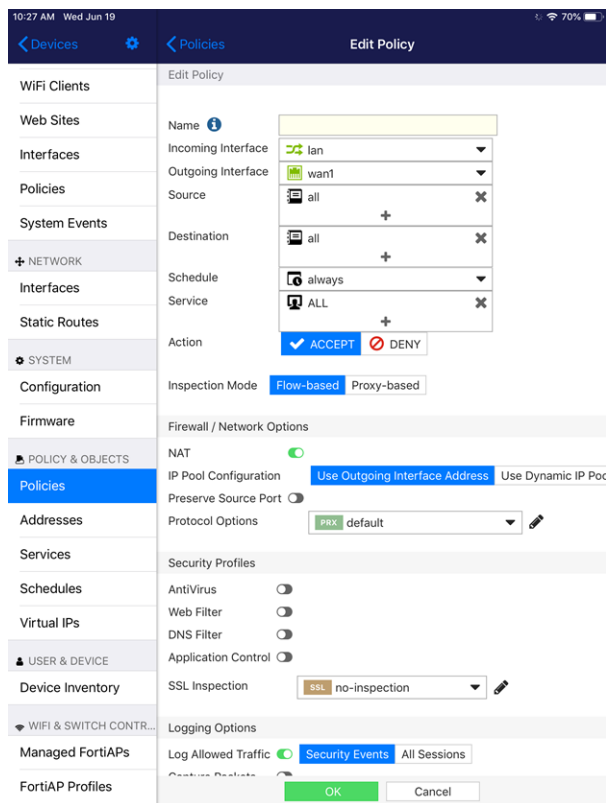

10. Go to **Network > Interfaces** and configure the local network (internal) interface.
11. Set the **Address** mode as before and configure **Administrative Access** if required.
12. Configure a **DHCP Server** for the internal network subnet.

13. Return to the internal interface using the < button at the top of the screen.
14. Go to **Network > Static Routes** and configure the static route to the gateway.

15. Go to **Policy & Objects > Firewall Policy** and edit the Internet access policy. Enter a **Name** for the policy, enable the required **Security Profiles**, configure **Logging Options**, then tap **OK**.

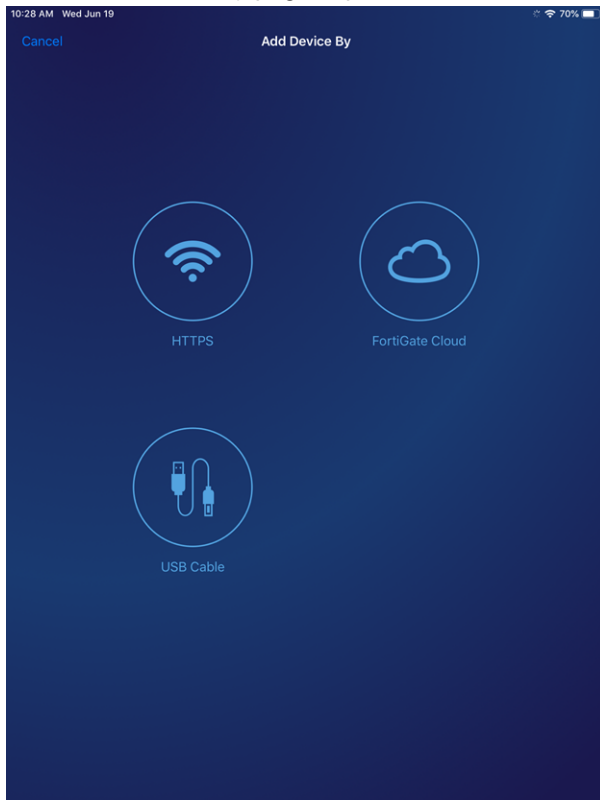

Connecting FortiExplorer to a FortiGate with WiFi

You can wirelessly connect to the FortiGate if your iOS device and the FortiGate are both connected to the same wireless network.

To connect and configure a FortiGate with FortiExplorer wirelessly:

1. Open the FortiExplorer app and tap *Add* on the *Devices* page.
2. On the *Add Device By* page, tap *HTTPS*.

3. Enter the *Host* information, *Username*, and *Password*.
4. If required, change the default *Port* number, and optionally enable *Remember Password*.

5. Tap *Done*.
6. If the FortiGate device identity cannot be verified, tap *Connect* at the prompt.
FortiExplorer opens the FortiGate management interface to the *Device Status* page.

Configure FortiGate with FortiExplorer using BLE

FortiGate 200F series and 80F series devices can be initially configured in FortiExplorer using Bluetooth Low Energy (BLE).

The state of the status LED on the device shows if BLE is enabled. See the device QuickStart guides for more information about LED states: [FortiGate 200F Series QuickStart Guide](#) and [FortiGate 80F Series QuickStart Guide](#).

When the status LED is flashing green, pressing and holding the reset button for five seconds or longer will reset the device to factory default settings.

BLE is enabled or disabled in the following scenarios after the FortiGate boots up:

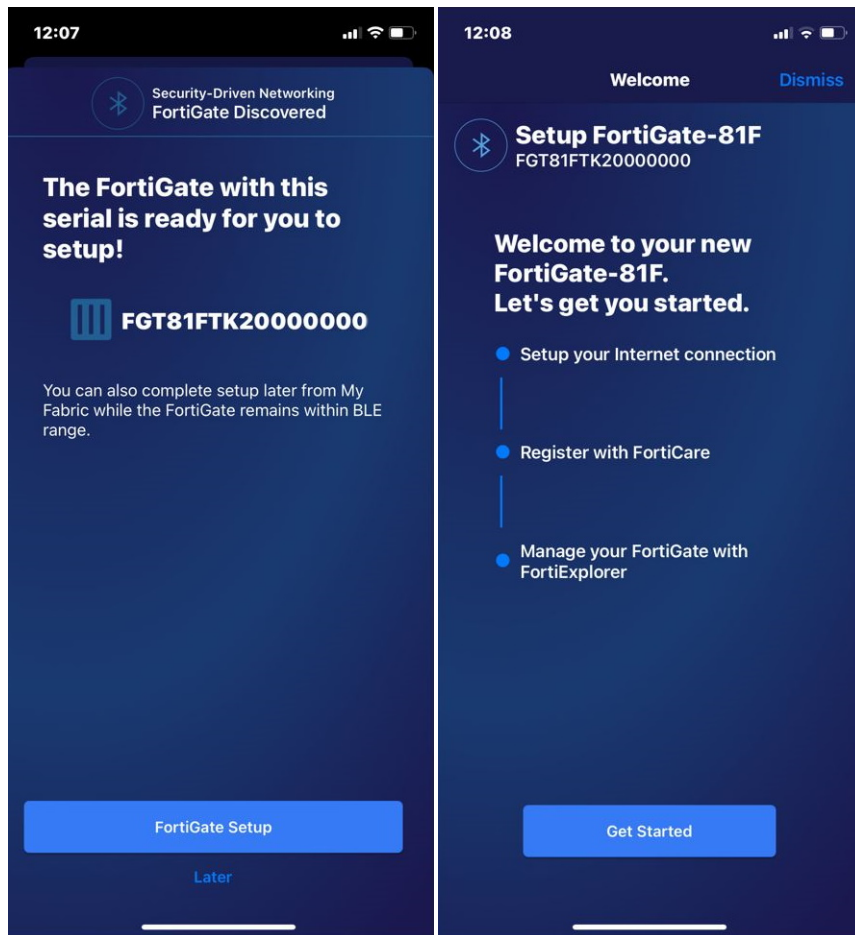

- In factory default settings:
 - After the FortiGate has finished booting up (when the console login prompt is shown), the status LED will be flashing amber or red to indicate that BLE is enabled.
 - If the FortiGate is configured without using BLE, BLE will immediately be disabled and the status LED will turn solid green.
 - If the FortiGate is configured using BLE, the LED will continue flashing until the configuring device disconnects from BLE, after which BLE is disabled and the status LED turns solid green.
- Not in factory default configuration:
 - One minute after the FortiGate has finished booting up (when the console login prompt is shown), the status LED will turn solid green. Press and hold the reset button for one second. The status LED will start flashing to indicate that BLE is enabled.
 - If no BLE connection is made with the FortiGate, BLE will be disabled after one minute and the status LED will turn solid green.
 - If the FortiGate is configured without using BLE, BLE will immediately be disabled and the status LED will turn solid green.
 - If the FortiGate is configured using BLE, the LED will continue flashing until the configuring device disconnects from BLE, after which BLE is disabled and the status LED turns solid green.

To enable BLE for one minute when the FortiGate is running and not in factory default configuration:

```
# diagnose bluetooth enable 1
```

To connect to and configure a FortiGate with FortiExplorer using BLE:

1. Ensure that BLE is enabled on the FortiGate device.
2. Enable Bluetooth on your iOS device and open the FortiExplorer app.
If the app has detected the FortiGate device, the device's serial number will be shown.

3. Log into the FortiGate in the app using the default credentials: *admin* and no password.
4. If this is the first time logging into the device, set a password.
5. Optionally, register with FortiCare.
6. Configure the FortiGate, including the WAN and internal interfaces, static routes, and other required settings.

After configuring the FortiGate and disconnecting, BLE is disabled.

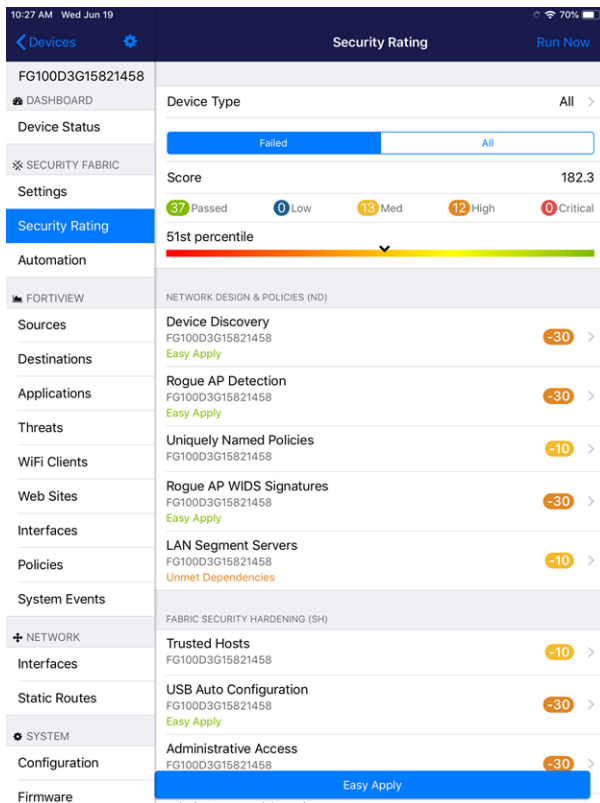

To check the status of BLE on the FortiGate:

```
# diagnose hardware test ble
# diagnose bluetooth status
# diagnose bluetooth get_bt_version
# diagnose bluetooth clean_bt_mode
```

Running a security rating

After configuring your network, run a security rating check to identify vulnerabilities and highlight best practices that could improve your network's security and performance.

Go to *Security Fabric > Security Rating* and follow the steps to determine the score. See [Security rating on page 2905](#) for more information.

Upgrading to FortiExplorer Pro

FortiExplorer Pro allows you to add unlimited devices, and download firmware images for devices with active licenses.

To upgrade to FortiExplorer Pro:

1. In FortiExplorer, go to *Settings*.
2. Tap *Manage Subscription*.
3. Follow the on-screen prompts.

Basic administration

This section contains information about basic FortiGate administration that you can do after you installing the unit in your network.

- [Basic configuration on page 63](#)
- [Registration on page 65](#)
- [FortiCare and FortiGate Cloud login on page 67](#)
- [Transfer a device to another FortiCloud account on page 70](#)
- [Configuration backups on page 72](#)
- [Deregistering a FortiGate on page 81](#)
- [Migrating a configuration with FortiConverter on page 82](#)

- [Fortinet Developer Network access on page 88](#)
- [One-time upgrade prompt when a critical vulnerability is detected upon login NEW on page 92](#)

Basic configuration

This topic will help you configure a few basic settings on the FortiGate as described in the [Using the GUI on page 25](#) and [Using the CLI on page 39](#) sections, including:

- [Configuring an interface on page 63](#)
- [Configuring the hostname on page 63](#)
- [Configuring the default route on page 64](#)
- [Ensuring internet and FortiGuard connectivity on page 64](#)
- [Using the default certificate for HTTPS administrative access on page 65](#)

Configuring an interface

It is unlikely the default interface configuration will be appropriate for your environment and typically requires some effort of the administrator to use these settings, such as being physically near the FortiGate to establish a serial connection. Therefore, the first step is to configure an interface that can be used to complete the FortiGate configuration.

To configure an interface in the GUI:

1. Go to *Network > Interfaces*. Select an interface and click *Edit*.
2. Enter an *Alias*.
3. In the *Address* section, enter the *IP/Netmask*.
4. In *Administrative Access* section, select the access options as needed (such as *PING*, *HTTPS*, and *SSH*).
5. Optionally, enable *DHCP Server* and configure as needed.
6. Click *OK*.

To configure an interface in the CLI:

```
config system interface
    edit "port2"
        set ip 203.0.113.99 255.255.255.0
        set allowaccess ping https ssh
        set alias "Management"
    next
end
```

Configuring the hostname

Setting the FortiGate's hostname assists with identifying the device, and it is especially useful when managing multiple FortiGates. Choose a meaningful hostname as it is used in the CLI console, SNMP system name, device name for FortiGate Cloud, and to identify a member of an HA cluster.

To configure the hostname in the GUI:

1. Go to *System > Settings*.
2. Enter a name in the *Host name* field.
3. Click *Apply*.

To configure the hostname in the CLI:

```
config system global
    set hostname 200F_YVR
end
```

Configuring the default route

Setting the default route enables basic routing to allow the FortiGate to return traffic to sources that are not directly connected. The gateway address should be your existing router or L3 switch that the FortiGate is connected to. If you are directly connecting to the FortiGate, you may choose your endpoint's IP address as the gateway address. Set the interface to be the interface the gateway is connected to.

To configure the default route in the GUI:

1. Go to *Network > Static Routes* and click *Create New*.
2. Leave the destination subnet as *0.0.0.0/0.0.0.0*. This is known as a default route, since it would match any IPv4 address.
3. Enter the *Gateway Address*.
4. Select an *Interface*.
5. Click *OK*.

To configure the default route in the CLI:

```
config router static
    edit 0
        set gateway 192.168.1.254
        set device port1
    next
end
```

Ensuring internet and FortiGuard connectivity

This step is not necessary for the configuration; however, it is necessary in order to keep your FortiGate up to date against the latest threats. Updates are provided to FortiGates that are registered and make a request to the FortiGuard network to verify if there are any more recent definitions.

Use `execute ping <domain.tld>` to ensure the DNS resolution is able to resolve the following FortiGuard servers:

- `fds1.fortinet.com`
- `service.fortiguard.net`
- `update.fortiguard.net`

You also need to ensure the necessary ports are permitted outbound in the event your FortiGate is behind a filtering device. Refer to the [Ports and Protocols](#) document for more information.

Using the default certificate for HTTPS administrative access

By default, the FortiGate uses the Fortinet_GUI_Server certificate for HTTPS administrative access. Administrators should download the CA certificate and install it on their PC to avoid warnings in their browser. See [Using the default certificate for HTTPS administrative access on page 2471](#) for more information.

Registration

The FortiGate, and then its service contract, must be registered to have full access to [Fortinet Customer Service and Support](#), and [FortiGuard](#) services. The FortiGate can be registered in either the FortiGate GUI or the FortiCloud support portal. The service contract can be registered from the FortiCloud support portal.

The service contract number is needed to complete registrations on the FortiCloud support portal. You can find this 12-digit number in the email that contains your service registration document (sent from do-not-reply-contract@fortinet.com) in the service entitlement summary.

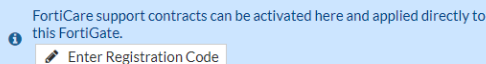

To register your FortiGate in the GUI:

1. Connect to the FortiGate GUI. A dialog box appears, which indicates the steps you should take to complete the setup of your FortiGate. These steps include:
 - a. *Register with FortiCare*
 - b. *Migrate Config with FortiConverter*
 - c. *Specify Hostname*
 - d. *Change Your Password*
 - e. *Dashboard Setup*
 - f. *Upgrade Firmware*

If you completed the [Basic configuration on page 63](#), the hostname and password steps are already marked as complete (checkmark). If you chose to deploy the latest firmware, the *Upgrade Firmware* step is marked as complete.

2. Click *Begin* to complete the dashboard setup. Two options appear (*Optimal* and *Comprehensive*).

3. Select the desired setting and click *OK*. The *Dashboard > Status* page opens. Note that the licenses are grayed out because the device or virtual machine is not registered.
4. Go to *System > FortiGuard* and click *Enter Registration Code*.

5. Enter the contract registration code from your service registration document.
6. Click OK.

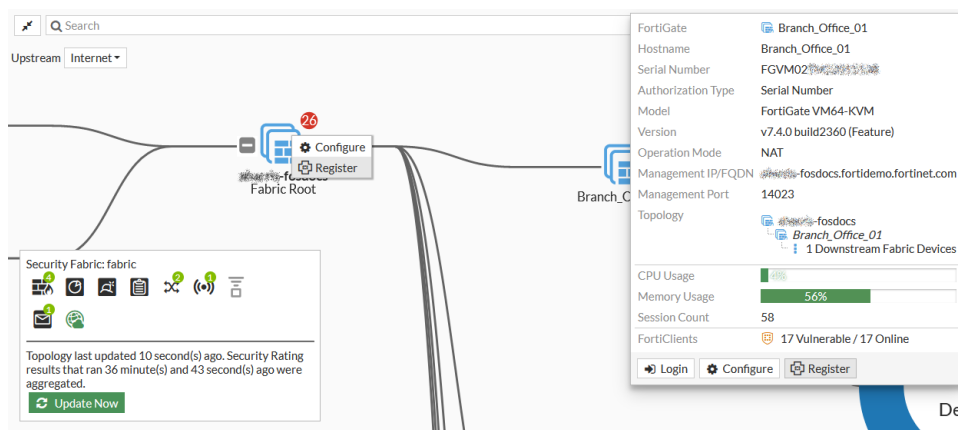

To register the FortiGate on the FortiCloud support portal:

FortiGates can be registered with the Register More button in the Products views. For details, see [Registering assets](#) in the [FortiCloud Account Services Asset Management](#) guide.

FortiCare Register button

The FortiCare *Register* button is displayed in the GUI on various Fabric and device related pages and widgets.

- To access the *Register* button on a topology page, click on or hover over the FortiGate device:

- To access the button from the *System > Firmware & Registration* or *System > HA* page, right-click on the device name.

The *Register* button is also accessible from tooltips for devices on the *Managed FortiAPs* and *Managed FortiSwitches* pages.

Clicking *Register* opens the *Device Registration* pane. If a device is already registered, the pane still opens and displays the device information.

Primary and secondary HA members can be registered to FortiCare at the same time from the primary unit by using the *Register* button. The secondary unit will register through the HA proxy.

In this example, a HA member is registered from the *Physical Topology* page.

To register a HA member to FortiCare:

1. On the primary unit, go to *Security Fabric > Physical Topology*, or expand the *Security Fabric* widget on the *Status* dashboard.
2. Hover over the HA member and click *Register*. The *Device Registration* pane opens.
3. Select the device and click *Register*.
4. Enter the required FortiCloud account information (password, country or region, reseller) and click *Submit*.
5. Once the registration is complete, click *Close*.

FortiCare and FortiGate Cloud login

With FortiCloud, FortiOS supports a unified login to FortiCare and FortiGate Cloud. The FortiGate Cloud setup is a subset of the FortiCare setup.

- If the FortiGate is not registered, activating FortiGate Cloud will force you to register with FortiCare.
- If a FortiGate is registered in FortiCare using a FortiCloud account, then only that FortiCloud account can be used to activate FortiGate Cloud.
- If a different FortiCloud account was already used to activate FortiGate Cloud, then a notification asking you to migrate to FortiCloud is shown in the GUI after upgrading FortiOS.

The CLI can be used to activate FortiGate Cloud without registration, or with a different FortiCloud account.

To activate FortiGate Cloud and register with FortiCare at the same time:

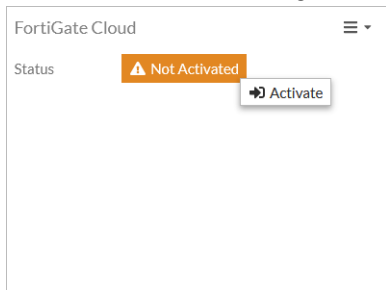

1. Go to *Dashboard > Status*.
2. In the FortiGate Cloud widget, click *Not Activated > Activate*.
You must register with FortiCare before activating FortiGate Cloud.

The screenshot shows the 'FortiCare Registration' dialog box. On the left, under 'System Information', the following details are listed: Hostname: FortiGate-101E, Serial Number, Firmware: v7.0.4, Mode: NAT, System Time: 2022/01/23 14:3, Uptime: 00:00:48:29, and WAN IP. The main area of the dialog is for registration. It shows 'FortiGate FG101E' with a flag icon. Below this are 'FortiCloud' buttons: 'Login' (highlighted in green) and 'Create Account'. There are input fields for 'Email', 'Password' (with a 'Forgot your password?' link), 'Country/Region' (a dropdown menu), and 'Reseller' (a dropdown menu). Below these is an 'End-user type' section with 'Non-government' (highlighted in green) and 'Government' buttons. At the bottom, there are two checkboxes: 'Sign in to FortiGate Cloud using the same account' (unchecked) and 'Allow administrative login using FortiCloud SSO' (checked). At the very bottom are 'OK' and 'Cancel' buttons.

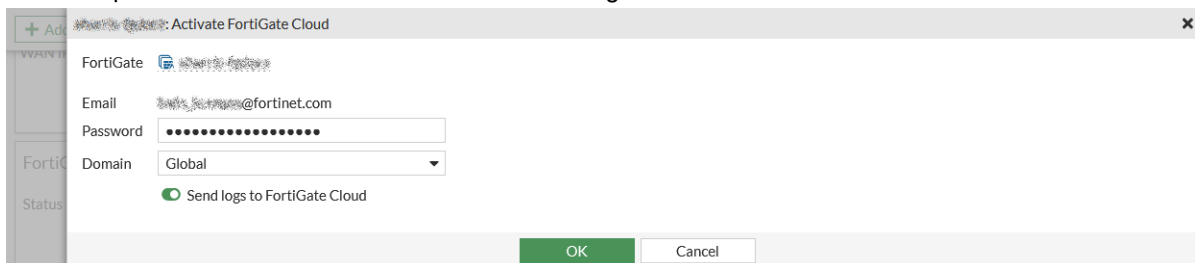

3. Enter your FortiCare *Email* address and *Password*.
4. Select your *Country/Region*, *Reseller*, and *End-user type*.
5. Enable *Sign in to FortiGate Cloud using the same account*.
6. Click *OK*.

To activate FortiGate Cloud on an already registered FortiGate:

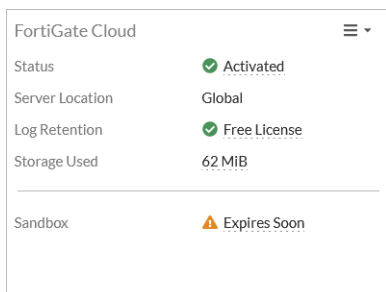

1. Go to *Dashboard > Status*.
2. In the *FortiGate Cloud* widget, click *Not Activated > Activate*.

3. Enter the password for the account that was used to register the FortiGate.

4. Click *OK*.
The *FortiGate Cloud* widget now shows the activated FortiCloud account.

**To migrate from the activated FortiGate Cloud account to the registered FortiCloud account:**

1. Go to *System > FortiGuard*.
2. In the *FortiCare Support* row, click *Actions > Transfer FortiGate to Another Account*.

The screenshot shows the FortiGuard Distribution Network interface. On the left, under 'License Information', there is a table with columns 'Entitlement' and 'Status'. The entitlements listed are FortiCare Support, Virtual Machine, Firmware & General Updates, Intrusion Prevention, AntiVirus, Web Filtering, Outbreak Prevention, SD-WAN Network Monitor, Industrial DB, and IoT Detection Service. All are in a 'Registered' or 'Valid' status with expiration dates of 2023/10/21. An 'Actions' dropdown menu is open, showing options like 'FortiCare Asset Management' and 'Transfer FortiGate to another account'. On the right, 'FortiGuard Updates' shows the next update time as 2023/05/09 15:56:00 and a button to 'Update Licenses & Definitions Now'. Below that, 'Manual Update' has a 'Load License File' button. At the bottom right, 'Service Communications' shows a table of services and their traffic volume over the last 24 hours.

Service	Traffic Volume (Last 24 hours)
FortiCare	0 B
FortiGate Cloud Log	0 B
FortiGuard.com	613.09 kB
FortiGuard Download	75.59 MB
FortiGuard Query	49.24 kB
FortiGate Cloud Sandbox	0 B

3. Enter the *Password* of the current FortiCloud account.

The screenshot shows the 'Transfer FortiGate to another account' dialog box. It has two tabs: '1 Verification' (active) and '2 Review and Transfer'. Under 'Current FortiCloud Account', there are fields for 'FortiCloud Account' (techdoc@fortinet.com) and 'Password' (masked with dots). Under 'Target FortiCloud Account', there are fields for 'FortiCloud Account' (techdoc@fortinet.com) and 'Password' (masked with dots). At the bottom, there are 'Next' and 'Cancel' buttons.

4. Enter the target *FortiCloud Account* name and *Password*, then click *Next*.
5. Review the information in the *From* and *To* fields, then click *Transfer*.

To activate FortiGate Cloud using an account that is not used for registration:

1. Enter the following with the credentials for the account being used to activate FortiGate Cloud:

```
# execute fortiguard-log login <account_id> <password>
```

2. Check the account type:

```
# diagnose fdsm contract-controller-update
Protocol=2.0|Response=202|Firmware=FAZ-4K-FW-2.50-
100|SerialNumber=FAMS000000000000|Persistent=false|ResponseItem=HomeServer:172.16.95.151
:443*AlterServer:172.16.95.151:443*Contract:20200408*NextRequest:86400*UploadConfig:False*
ManagementMode:Local*ManagementID:737941253*AccountType:multitenancy

Result=Success
```

A FortiCloud account that is not used for the support portal account cannot be used to register FortiGate. Attempting to activate FortiGate Cloud with this type of account will fail.

Transfer a device to another FortiCloud account

Master account users can transfer a device from one FortiCloud/FortiCare account to another. Users can transfer a device up to three times within a twelve-month time period. If more transfers are required within the twelve-month time period, contact [Technical Support](#) to request the transfer.

Requirements:

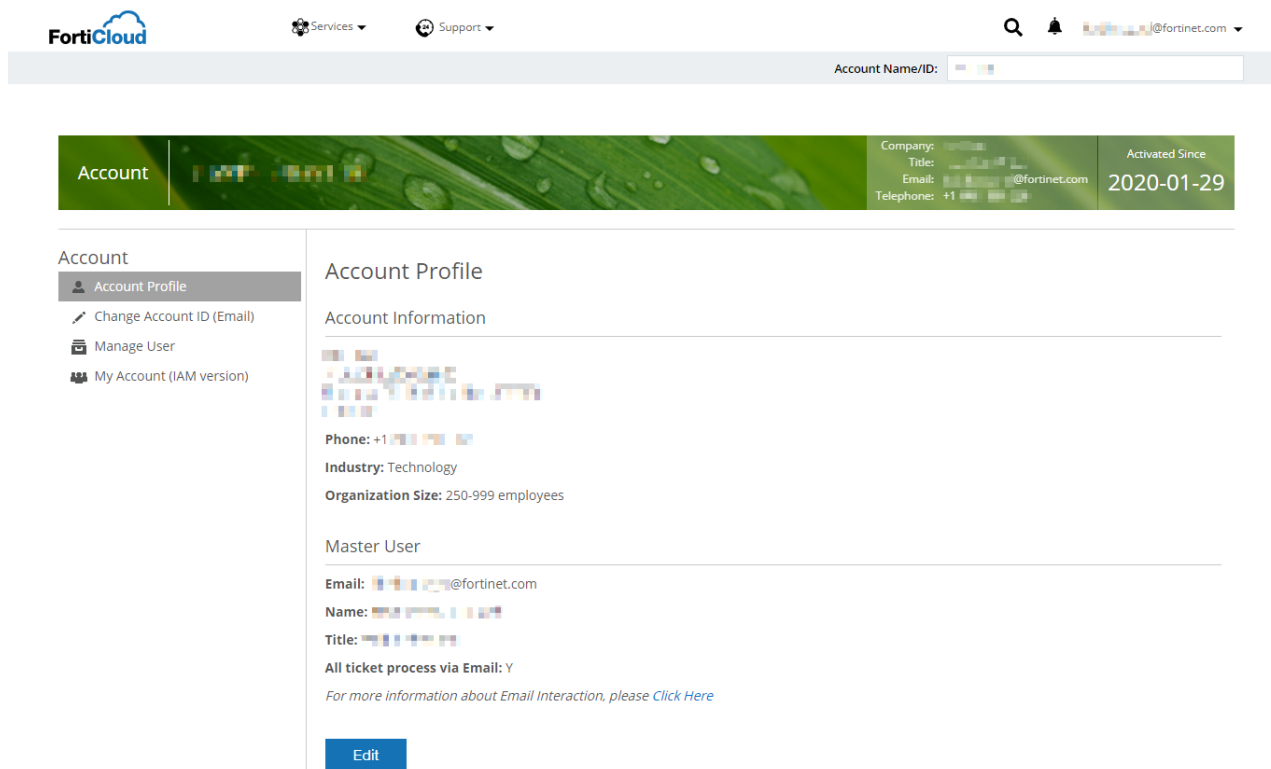

To transfer an account, you must:

- Have access to the FortiGate, as well as both the FortiCloud and FortiCare accounts.
- Be a master account user.

To verify if you are the master account user, log in to support.fortinet.com. Click the username, then select *My Account*.

The *Account Profile* page opens.

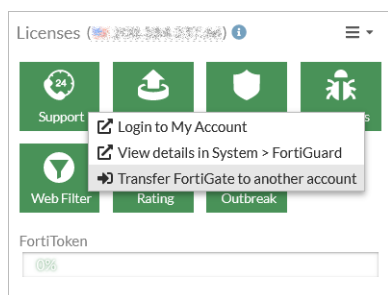

To transfer an account in the GUI:

1. Go to *Dashboard > Status*.
2. In the *Licenses* widget, click the *Support* link, then click *Transfer FortiGate to Another Account*.

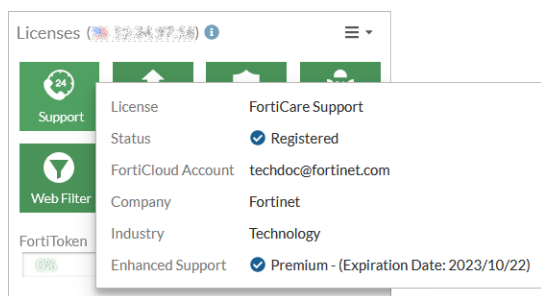

You can also transfer an account from *System > FortiGuard*.

3. In the *Current FortiCloud Account* fields, enter the username and password for the current account. In the *Target FortiCloud Account* fields, enter the new username and password.
4. Click *Next*.

5. Review the information, then click *Transfer*.

After the transfer is complete, the new the FortiCloud account is displayed in the *Licenses* widget.

Configuration backups

Once you successfully configure the FortiGate, it is extremely important that you back up the configuration. In some cases, you may need to reset the FortiGate to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it.

You can use the GUI or CLI to back up the configuration in FortiOS or YAML format. You have the option to save the configuration file in FortiOS format to various locations including the local PC, USB key, FTP, and TFTP server. FTP and TFTP are only configurable through the CLI. In YAML format, configuration files can be backed up or restored on an FTP or TFTP server through the CLI.

This topic includes the following information:

- [Backing up and restoring configurations from the GUI on page 72](#)
- [Backing up and restoring configurations from the CLI on page 75](#)
- [Configuration revision on page 79](#)
- [Restore factory defaults on page 80](#)
- [Secure file copy on page 80](#)

Backing up and restoring configurations from the GUI

Configurations can be backed up using the GUI to your PC or a USB disk.

Field	Description
Scope	When the FortiGate is in multi-vdom mode and a user is logged in as a global administrator.
Backup to	<p>You can choose where to save the configuration backup file.</p> <ul style="list-style-type: none"> • <i>Local PC</i>: Save the configuration file to your PC. • <i>USB Disk</i>: Save the configuration file to an external USB disk. This option is not available if there is no USB drive inserted in the USB port. <p>You can also back up to FortiManager using the CLI.</p>
File format	The configuration file can be saved in FortiOS or YAML format.

Field	Description
Password mask	Use password masking when sending a configuration file to a third party. When password masking is enabled, passwords and secrets will be replaced in the configuration file with <code>FortinetPasswordMask</code> .
Encryption	Enable <i>Encryption</i> to encrypt the configuration file. A configuration file cannot be restored on the FortiGate without a set password. Encryption must be enabled on the backup file to back up VPN certificates.

To back up the configuration in FortiOS format using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration > Backup*.
2. Direct the backup to your *Local PC* or to a *USB Disk*.
3. Enable *Encryption*.

This is recommended to secure your backup configurations and prevent unauthorized parties from reloading your configuration.

4. Enter a password, and enter it again to confirm it. This password will be required to restore the configuration.
5. Click *OK*.
6. When prompted, select a location on the PC or USB disk to save the configuration file. The configuration file will have a `.conf` extension.

To back up the configuration in YAML format using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration > Backup*.
2. Direct the backup to your *Local PC* or to a *USB Disk*.
3. Select *YAML* for the *File format*.
4. Click *OK*.

When backing up a configuration that will be shared with a third party, such as Fortinet Inc. Support, passwords and secrets should be obfuscated from the configuration to avoid information being unintentionally leaked. Password masking can be completed in the *Backup System Configuration* page and in the CLI. When password masking is enabled, passwords and secrets will be replaced in the configuration file with `FortinetPasswordMask`.

To mask passwords in the GUI:

1. Click on the username in the upper right-hand corner of the screen and select *Configuration > Backup*.
2. Select *YAML* as the *File format*.
3. Enable *Password mask*. A warning message is displayed.

Backup System Configuration

Backup to: Local PC USB Disk

File format: FortiOS YAML

Password mask: ☒

Warning: This config is intended to be used for submission to Fortinet support. It should not be used to restore the FortiGate.

Encryption: ☒

OK Cancel

4. Click **OK**. The configuration file is saved to your computer with passwords and secrets obfuscated.

The following is an example of output with password masking enabled:

```
config system admin
  edit "1"
    set accprofile "prof_admin"
    set vdom "root"
    set password FortinetPasswordMask
  next
end
config vpn ipsec phase1-interface
  edit "vpn-1"
    set interface "port1"
    set peertype any
    set net-device disable
    set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
    set comments "VPN: vpn-1 (Created by VPN wizard)"
    set wizard-type static-fortigate
    set remote-gw 172.16.200.55
    set psksecret FortinetPasswordMask
  next
end
config wireless-controller vap
  edit "ssid-1"
    set passphrase FortinetPasswordMask
    set schedule "always"
  next
end
```

Restoring configuration files from the GUI

Configuration files can be used to restore the FortiGate to a previous configuration in the *Restore System Configuration* page.

To restore the FortiGate configuration using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration > Restore*.
2. Identify the source of the configuration file to be restored: your *Local PC* or a *USB Disk*.
The *USB Disk* option will not be available if no USB drive is inserted in the USB port. You can restore from the FortiManager using the CLI.
3. Click *Upload*, locate the configuration file, and click *Open*.
4. Enter the password if required.
5. Click *OK*.

When restoring a configuration file that has password masking enabled, obfuscated passwords and secrets will be restored with the password mask.

Restoring the FortiGate with a configuration with passwords obfuscated is not recommended.

To restore an obfuscated YAML configuration using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration > Restore*.
2. Click *Upload*. The File Explorer is displayed.
3. Navigate to the configuration file and click *Open*.

4. (Optional) Enter the file password in the *Password* field.
5. Click *OK*. The *Confirm* pane is displayed with a warning.

6. Toggle the acknowledgment.
7. Click *OK*.

Backing up and restoring configurations from the CLI

Configuration backups in the CLI are performed using the `execute backup` commands and can be backed up in FortiOS and YAML format.

Configuration files can be backed up to various locations depending on the command:

- `flash`: Backup the configuration file to the flash drive.
- `ftp`: Backup the configuration file to an FTP server.
- `management-station`: Backup the configuration file to a management station, such as FortiManager or FortiGate Cloud.
- `sftp`: Backup the configuration file to a SFTP server.
- `tftp`: Backup the configuration file to a TFTP server.
- `usb`: Backup the configuration file to an external USB drive.
- `usb-mode`: Backup the configuration file for USB mode.

Command	Description
# execute backup config	<p>Back up the configuration in FortiOS format.</p> <p>Backup your configuration file to:</p> <ul style="list-style-type: none"> • flash • ftp • management-station • sftp • tftp • usb • usb-mode
# execute backup full-config	<p>Backup the configuration, including backups of default configuration settings.</p> <p>Backup your configuration file to:</p> <ul style="list-style-type: none"> • ftp • sftp • tftp • usb • usb-mode
# execute backup yaml-config	<p>Backup the configuration in YAML format.</p> <p>Backup your configuration file to:</p> <ul style="list-style-type: none"> • ftp • tftp
# execute backup obfuscated-config	<p>Backup the configuration with passwords and secrets obfuscated.</p> <p>Backup your configuration file to:</p> <ul style="list-style-type: none"> • ftp • management-station • sftp • tftp • usb
# execute backup obfuscated-full-config	<p>Backup the configuration (including default configuration settings) with passwords and secrets obfuscated.</p> <p>Backup your configuration file to:</p> <ul style="list-style-type: none"> • ftp • sftp • tftp • usb
# execute backup obfuscated-yaml-config	<p>Backup the configuration in YAML format with passwords and secrets obfuscated.</p> <p>Backup your configuration file to:</p> <ul style="list-style-type: none"> • ftp • tftp

To back up the configuration in FortiOS format using the CLI:

For FTP, note that port number, username are optional depending on the FTP site:

```
# execute backup config ftp <backup_filename> <ftp_server>[:<ftp_port>] [<user_name>]
[<password>] [<backup_password>]
```

or for TFTP:

```
# execute backup config tftp <backup_filename> <tftp_servers> [<backup_password>]
```

or for SFTP:

```
# execute backup config sftp <backup_filename> <sftp_server>[:<sftp_port>] <user> <password>
[<backup_password>]
```

or:

```
# execute backup config management-station <comment>
```

or:

```
# execute backup config usb <backup_filename> [<backup_password>]
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom
    edit <vdom_name>
```

See [Backing up and restoring configurations in multi VDOM mode on page 2488](#) for more information.

When backing up a configuration in YAML format, if it is not already specified in the file name, `.yaml` will be appended to the end. For example, if the file name entered is `301E.conf`, the name will become `301E.conf.yaml` after the configuration is backed up.

To back up the configuration in YAML format using the CLI:

```
# execute backup yaml-config {ftp | tftp} <filename> <server> [username] [password]
```

For example:

```
# execute backup yaml-config tftp 301E.conf 172.16.200.55
Please wait...
The suffix '.yaml' will be appended to the filename if user does not add it
specifically.
Connect to tftp server 172.16.200.55 ...
#
Send config file to tftp server OK.
```

Configuration files can be configured with obfuscated passwords and secrets to not unintentionally leak information when sharing configuration files with third parties.

To mask passwords in a configuration backup in the CLI:

```
# execute backup obfuscated-config {ftp | management-station | sftp | tftp | usb}
```

To mask passwords in the full configuration backup in the CLI:

```
# execute backup obfuscated-full-config {ftp | sftp | tftp | usb}
```

To mask passwords in a configuration backup with YAML formatting in the CLI:

```
# execute backup obfuscated-yaml-config {ftp | tftp}
```

If a configuration is being backed up on a server, server information must be included with the command. Other information that may be required with an `execute backup` command includes file names, passwords, and comments.

Restoring configuration files from the CLI

Configuration files can be used to restore the FortiGate using the CLI.

Command	Description
<code># execute restore config</code>	<p>Restore a configuration that is in FortiOS or YAML format. The file format is automatically detected when it is being restored.</p> <p>Configurations can be loaded from:</p> <ul style="list-style-type: none"> • <code>flash</code>: Load the configuration file from flash to firewall. • <code>ftp</code>: Load the configuration file from an FTP server. • <code>management-station</code>: Load the configuration from a management station. • <code>tftp</code>: Load the configuration from from a TFTP server. • <code>usb</code>: Load the configuration file from an external USB disk to firewall. • <code>usb-mode</code>: Load the configuration file from an external USB disk and reboot.

To restore the FortiGate configuration using the CLI:

For FTP, note that port number, username are optional depending on the FTP site:

```
# execute restore config ftp <backup_filename> <ftp_server>[:<port>] [<user_name>]
[<password>] [<backup_password>]
```

or for TFTP:

```
# execute restore config tftp <backup_filename> <tftp_server> [<backup_password>]
```

For restoring the configuration from FortiManager or FortiGate Cloud:

```
# execute restore config management-station normal <revision ID>
```

or:

```
# execute restore config usb <backup_filename> [<backup_password>]
```

The FortiGate will load the configuration file and restart. Once the restart has completed, verify that the configuration has been restored.

Troubleshooting

When restoring a configuration, errors may occur, but the solutions are usually straightforward.

Error message	Reason and Solution
Configuration file error	<p>This error occurs when attempting to upload a configuration file that is incompatible with the device. This may be due to the configuration file being for a different model or being saved from a different version of firmware.</p> <p>Solution: Upload a configuration file that is for the correct model of FortiGate device and the correct version of the firmware.</p>
Invalid password	<p>When the configuration file is saved, it can be protected by a password. The password entered during the upload process is not matching the one associated with the configuration file.</p> <p>Solution: Use the correct password if the file is password protected.</p>

Configuration revision

You can manage multiple versions of configuration files on models that have a 512MB flash memory and higher. Revision control requires either a configured central management server or the local hard drive, if your FortiGate has this feature. Typically, configuration backup to local drive is not available on lower-end models.

Central management server

The central management server can either be a FortiManager unit or FortiGate Cloud.

If central management is not configured on your FortiGate, a message appears instructing you to either enable central management, or obtain a valid license.

To enable central management from the GUI:

1. Go to *Security Fabric > Fabric Connectors* and double-click the *Central Management* card.
2. Set the *Status* to *Enabled* and select a *Type*.
3. Click *OK*.

To enable central management from the CLI:

```
config system central-management
    set type {fortimanager | fortiguard}
    set mode backup
    set fmg <IP address>
end
```

To backup to the management server:

```
# execute backup config management-station <comment>
```

To view a backed up revision:

```
# execute restore config management-station normal 0
```

To restore a backed up revision:

```
# execute restore config management-station normal <revision ID>
```

Backing up to a local disk

When revision control is enabled on your FortiGate unit, and configuration backups have been made, a list of saved revisions of those backed-up configurations appears.

Configuration backup occurs by default with firmware upgrades but can also be configured to occur every time you log out.

To configure configuration backup when logging out:

```
config system global
  set revision-backup-on-logout enable
end
```

To manually force backup:

```
# execute backup config flash <comment>
```

Configuration revisions are viewed by clicking on the user name in the upper right-hand corner of the screen and selecting *Configuration > Revisions*.

To view a list of revisions backed up to the disk from the CLI:

```
# execute revision list config
```

To restore a configuration from the CLI:

```
# execute restore config flash <revision ID>
```

Restore factory defaults

There may be a need to reset the FortiGate to its original defaults; for example, to begin with a fresh configuration. There are two options when restoring factory defaults. The first resets the entire device to the original out-of-the-box configuration.

You can reset the device with the following CLI command:

```
# execute factoryreset
```

When prompted, type *y* to confirm the reset.

Alternatively, in the CLI you can reset the factory defaults but retain the interface and VDOM configuration with the following command:

```
# execute factoryreset2
```

Secure file copy

You can also back up and restore your configuration using Secure File Copy (SCP). See [How to download a FortiGate configuration file and upload firmware file using secure file copy \(SCP\)](#).

You enable SCP support using the following command:

```
config system global
    set admin-scp enable
end
```

For more information about this command and about SCP support, see [config system global](#).

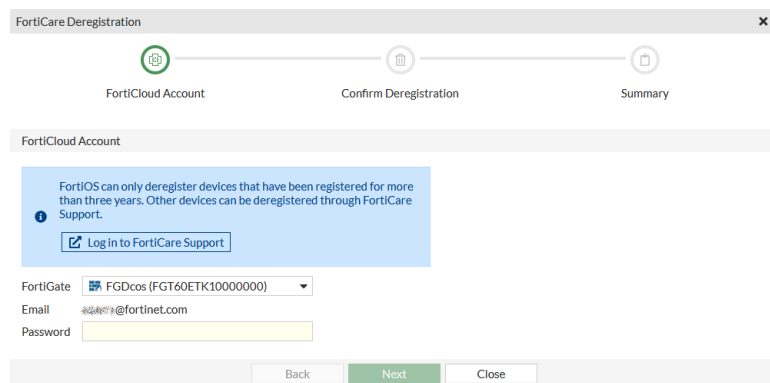

Deregistering a FortiGate

An administrator can deregister a FortiGate, if the device has been registered for three or more years, using the GUI or CLI, without having to contact FortiCare administration. After the device is deregistered, all associated contracts are also deregistered, and all of the administrator's information is wiped.

To deregister the FortiGate in the GUI:

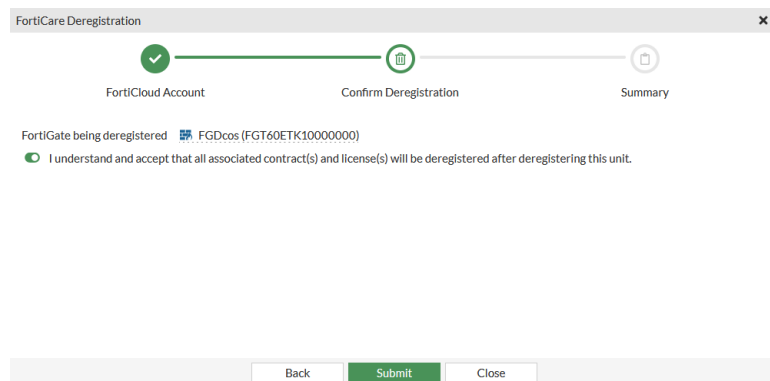

1. Go to *System > FortiGuard* and in the *Forticare Support* row select *Actions > Deregister FortiGate*.

The FortiCare Deregistration pane opens.

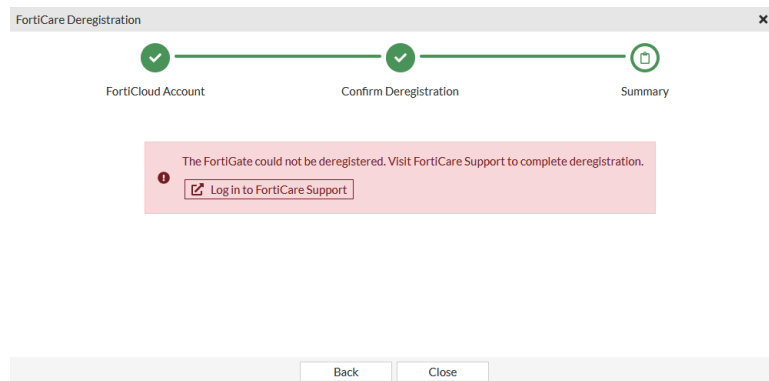

The screenshot shows the 'FortiCare Deregistration' pane with a progress bar at the top. The first step, 'FortiCloud Account', is active and highlighted with a green circle. Below the progress bar, there is a blue information box stating: 'FortiOS can only deregister devices that have been registered for more than three years. Other devices can be deregistered through FortiCare Support.' with a 'Log in to FortiCare Support' button. Below this, there are input fields for 'FortiGate' (a dropdown menu showing 'FGDcos (FGT60ETK10000000)'), 'Email' (a text field with '@fortinet.com'), and 'Password' (a masked text field). At the bottom, there are three buttons: 'Back', 'Next' (highlighted in green), and 'Close'.

2. Enter your password then click *Next*.
3. Confirm the FortiGate deregistration then click *Submit*.

The screenshot shows the 'FortiCare Deregistration' pane with the progress bar updated. The second step, 'Confirm Deregistration', is now active and highlighted with a green circle. The first step, 'FortiCloud Account', is now completed and shown with a green checkmark. Below the progress bar, it says 'FortiGate being deregistered' followed by the device ID 'FGDcos (FGT60ETK10000000)'. There is a green circle icon and a checkbox labeled 'I understand and accept that all associated contract(s) and license(s) will be deregistered after deregistering this unit.' At the bottom, there are three buttons: 'Back', 'Submit' (highlighted in green), and 'Close'.

If the FortiGate has been registered for less than three years, the deregistration will fail.

To deregister the FortiGate in the CLI:

```
# diagnose forticare direct-registration product-deregister <accountID> <password>
```

If the FortiGate has been registered for less than three years, the deregistration will fail:

```
forticare_product_deregister:1335: Failed to get response (rc = 0, http_code = 403)
Unit deregistration unsuccessful.
```

Migrating a configuration with FortiConverter

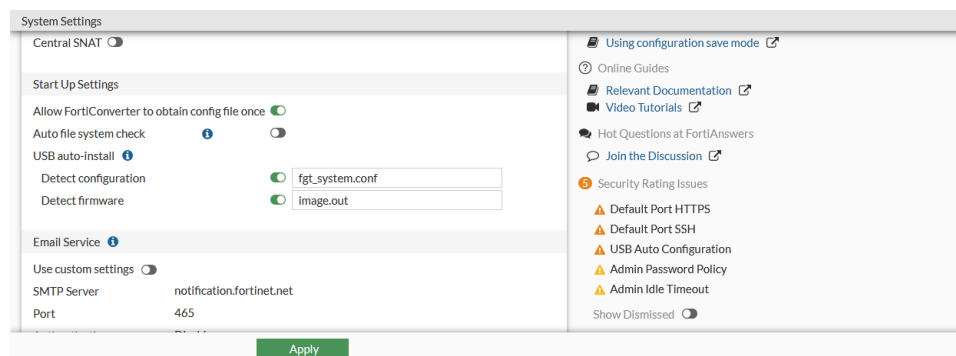

A configuration can be migrated from an older FortiGate device to a new FortiGate device directly from the FortiGate GUI, without having to access the FortiConverter portal.

Both the source and target FortiGates must be registered under the same FortiCare account and have internet connectivity to reach the FortiConverter server. The target FortiGate must also have a valid FortiConverter license.

In this example, FortiGate A (FGTA) is replacing FortiGate B (FGTB). The configuration is migrated using FortiConverter, but without accessing the FortiConverter portal.

To migrate the configuration from FGTB to FGTA in the GUI:

1. On FGTB, go to **System > Settings**, enable *Allow FortiConverter to obtain config file once*, then click **Apply**.

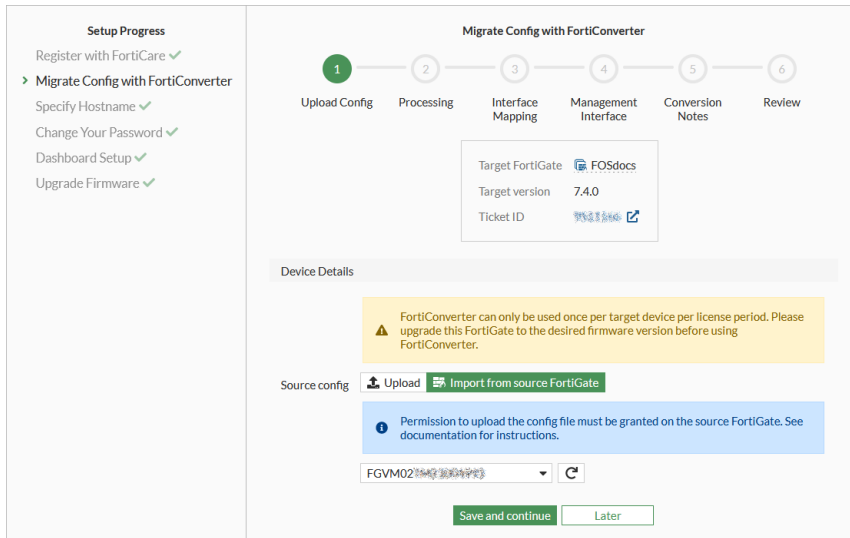

2. Log in to FGTA and on the GUI startup menu click **Begin** to start *Migrate Config with FortiConverter*.

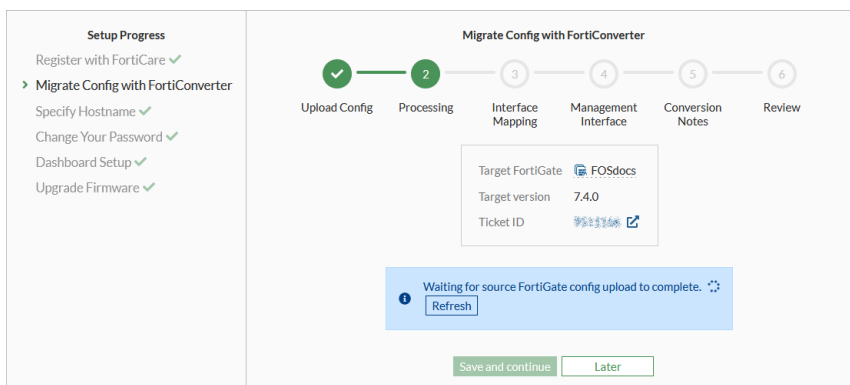

3. Click **Convert** to create a FortiConverter ticket.

You can toggle the *Don't show again* option to turn off reminders about the migration process.

4. Select **Import from source FortiGate**, then select the source FortiGate.

5. Click **Save and continue**, then wait for the FGTM configuration file to be uploaded to the ticket. After the configuration is uploaded, the *Allow FortiConverter to obtain config file once* is automatically disabled on FGTM.

6. Define the interface mapping between the source and target FortiGates, then click **Save and continue**.

Submit Previous step Later

10. Confirm the conversion process by clicking *OK*.

The conversion request is sent, and an email is sent to confirm that the conversion process has started in FortiConverter.

Sample email message:

*** This is a System Generated Message. Please do not reply to this email! ***

Dear FortiConverter User,

A new ticket XXXXXXXX has been created. You can expect an initial response with one business day.

<https://service.forticonverter.com/ticket/detail/XXXXXXX>

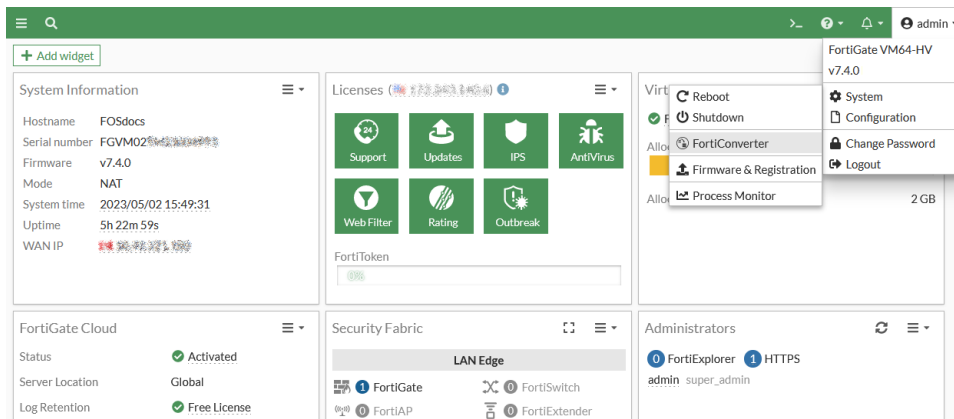

Ticket#: XXXXXXXX

Subject: FortiConverter Service for FortiGate [FGVM02XX00000000]

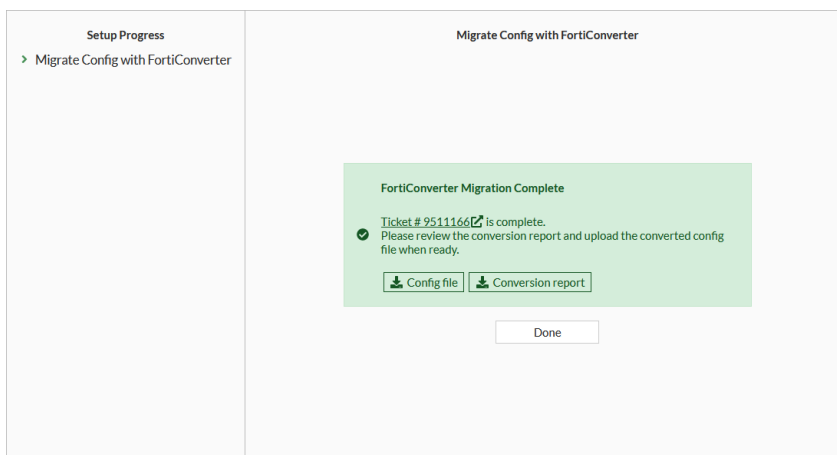

Regards,

Fortinet Converter Service and Support

11. Click *Done*. The conversion can take a few days.
12. To check the status of the conversion process, click your administrator name and select *System > FortiConverter*.

If the conversion is complete, the configuration file and conversion report can be downloaded.

13. When the conversion process completes, you will receive an email and a notifications in the FortiGate GUI.

Sample email message:

*** This is a System Generated Message. Please do not reply to this email! ***

Dear FortiConverter User,

<https://service.forticonverter.com/ticket/detail/XXXXXXX>

Ticket#: XXXXXXX

Subject: FortiConverter Service for FortiGate [FGVM02XX00000000]

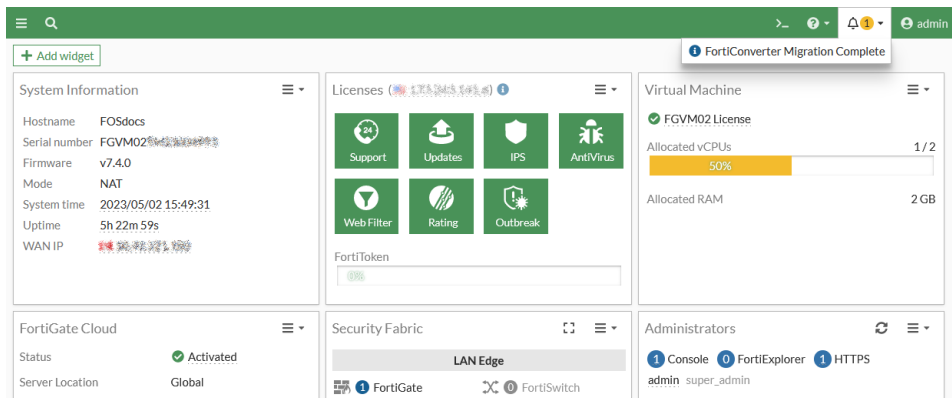

Ticket Status: Service Delivered

The converted config file and a summary report of the configuration conversion have been uploaded to the ticket 9511166 under the "Converted Config File" section. Please login to the FortiConverter Service Portal to download the files for review and let us know if you have any questions about the conversion.

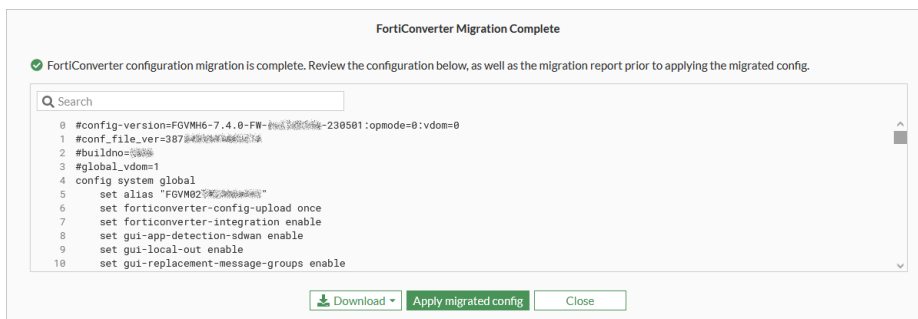

Your opinion matters to us and we would love to hear more about your experience with FortiConverter service. The survey can be accessed on the right side of the ticket in our service portal. Your feedback will help us to improve FortiConverter service and we look forward to hearing from you.

Regards,

Fortinet Converter Services and Support

14. Click the notification to review the configuration file, download the conversion report and the migrated configuration, or apply the configuration to the FortiGate.

- a. Select *Download > Conversion report* to download a PDF version of the conversion report.
 - b. Select *Download > Migrated config* to download the new configuration file.
 - c. Click *Apply migrated config* to immediately apply the new configuration file. This will cause the device to reboot.
 - d. Click *Close* if you need to review the configuration file and manually apply it later.
15. To manually load to configuration file, click your administrator name and select *Configuration > Restore*.

- 16.** Upload the converted configuration file, then click *OK*. This will cause the device to reboot.

Fortinet Developer Network access

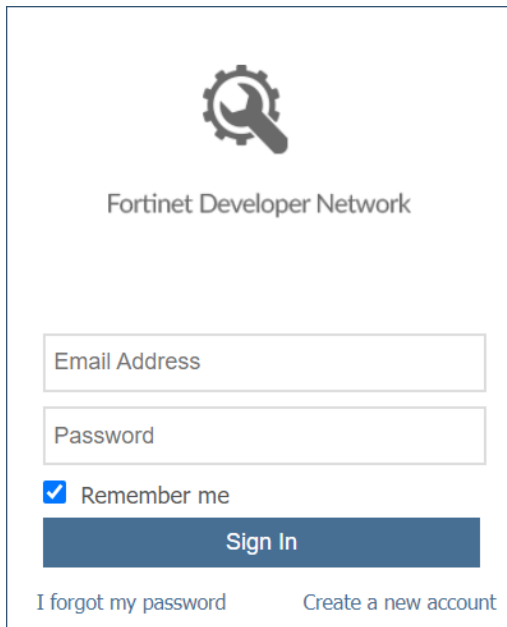

The [Fortinet Developer Network](#) (FNDN) is a subscription-based community that helps administrators enhance and increase the effectiveness of Fortinet products. Administrators can access the FortiAPI forum in FNDN to help create applications that interact with Fortinet products, such as custom web portals, automated deployment and provisioning systems, and scripted tasks. FNDN makes it easy for administrators and Fortinet professionals to interact, share sample code, and upload their own tools. The [FortiOS REST API](#) documentation is available within the FortiAPI forum.

All FNDN users must be sponsored by two Fortinet employees. The sponsors must be able to confirm the user's identity and need for access. Approvals from both sponsors are required before access is granted to new users. The sponsors' email addresses are required to create a new FNDN account.

Basic and licensed access options are available. Refer to the [Fortinet Developer Network](#) data sheet for more information.

To create an FNDN account:

1. Obtain sponsorship from two Fortinet employees.
2. Go to the FNDN website, <https://fndn.fortinet.net/>. The log in page appears.

Fortinet Developer Network

Company size

Security Check

☐ I'm not a robot

reCAPTCHA
[Privacy](#) - [Terms](#)

☐ I agree to the [Terms of Use](#) *

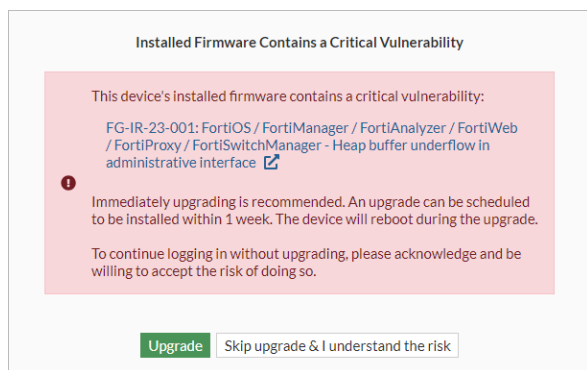

Create my Account

5. Click *Create my Account*.

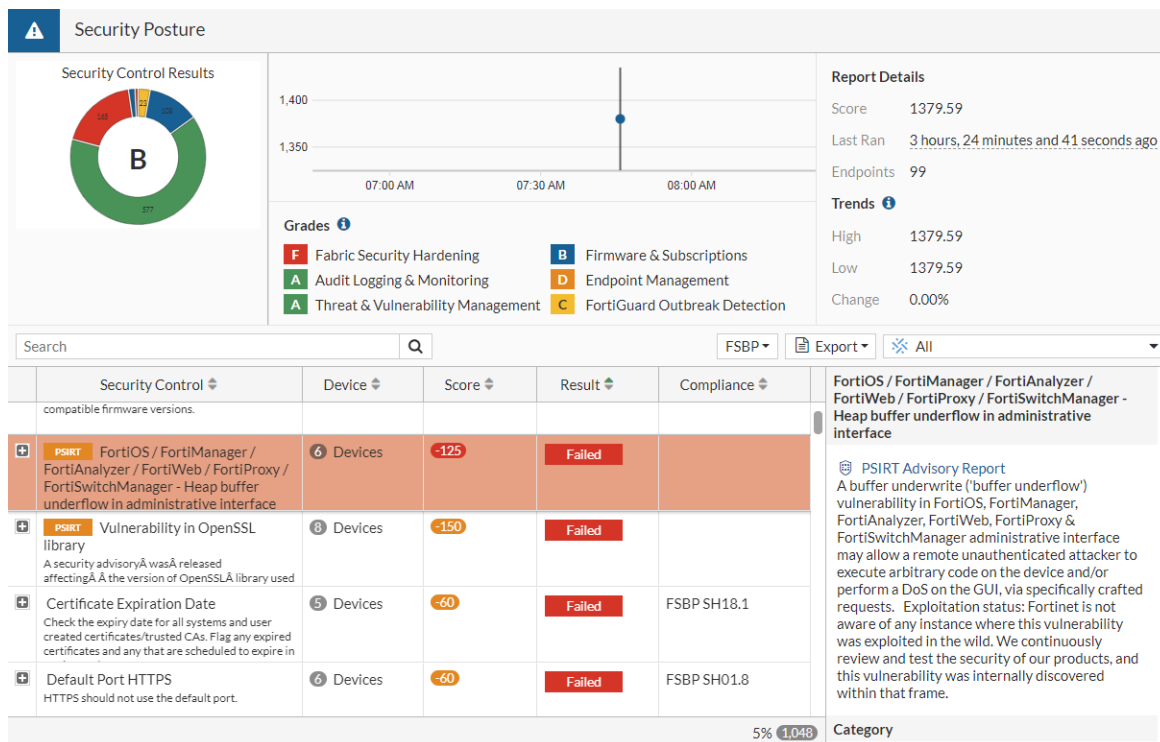

New accounts are reviewed and approved by an FNDN administrator. After both sponsors approve the request, an FNDN administrator reviews the request and approves account access in around one business day if all requirements are met.

One-time upgrade prompt when a critical vulnerability is detected upon login - NEW

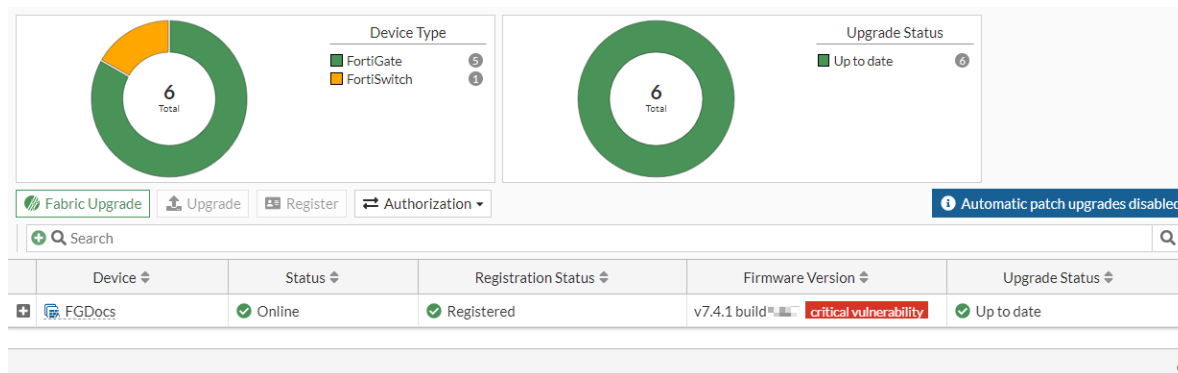

When FortiOS detects a critical vulnerability, a prompt appears for a one-time upgrade after logging into the FortiGate. A warning message is displayed in the GUI about the critical vulnerability and allows the administrator to either upgrade or skip it. This ensures that the administrator is aware of any potential security risks and can take immediate action to address them.

Clicking the hyperlinked vulnerability name opens the *Security Fabric > Security Rating* page, which displays more information about the vulnerability. See [PSIRT-related notifications on page 2908](#) for more information.

Clicking the *Upgrade* button opens the *System > Firmware & Registration* page where the administrator can upgrade the device. See [Firmware & Registration on page 2418](#) for more information.

Clicking the *Skip upgrade & I understand the risk* button continues the log in process as usual.

Diagnostics

To view vulnerability results after performing security rating scan:

```
# diagnose report-runner vuln-read
Index: 0
Name: FG-IR-23-001: FortiOS / FortiManager / FortiAnalyzer / FortiWeb / FortiProxy /
FortiSwitchManager - Heap buffer underflow in administrative interface
FortiGate Serial: FGVM02TM23000000
```

To clear the vulnerability result:

```
# diagnose report-runner vuln-clean
Deleted temporary critical vulnerability file
```

LEDs

Check your device's QuickStart guide for specific LED information: [FortiGate QuickStart Guides](#).

The following faceplates show where the LEDs are typically found on FortiGate models:

LED	State	Description
Logo	Green	The unit is on
	Blue	The FortiWiFi unit is on
	Off	The unit is off
Power (PWR)	Green	The unit is on and/or both power supplies are functioning
	Amber	One power supply is functioning
	Flashing Amber	Power supply failure
	Red	The unit is on, but only one power supply is functional
	Flashing Red	Power failure
	Off	The unit is off
Status (STA)	Green	Normal
	Flashing Green	Booting up
	Amber	Major or minor alarm
	Flashing Amber	BLE is on
	Red	Major alarm
	Flashing Red	BLE is on
	Off	The unit is off
Bypass (BYP)	Amber	Bypass Port Pair is active
	Off	Bypass Port Pair is off

LED	State	Description
Alarm	Red	Major alarm
	Amber	Minor alarm
	Off	No alarms
HA	Green	Operating in an HA cluster
	Amber or Red	HA failover
	Off	HA disabled
Max PoE	Green, Amber, or Red	Maximum PoE power allocated
	Off	PoE power available or normal
PoE	Green	Power delivered
	Flashing Green	Error or PoE device requesting power
	Off	No PoE device connected or no power delivered
SVC	Green	SVC is on
	Flashing Green	SVC activity
	Off	SVC is off
3G / 4G	Green	3G / 4G service is on
	Flashing Green	3G / 4G activity
	Off	3G / 4G service is off
WiFi	Green	WiFi connected
	Flashing Green	WiFi activity
	Off	WiFi is off
Power Supply	Green	Power supply operating normally
	Flashing Green	Power detected, but power supply not providing power or is in standby mode
	Amber	Power output is off, there is a power supply error, or there is no input power but the redundant supply is on
	Flashing Amber	Power supply error or warning events, or the power supply should be replaced
	Red	Cord unplugged or power lost
	Flashing Red	Power supply warning events
	Off	Power not detected

LED	State	Description
Power Supply OK	Green	Standby rail and main output on
	Flashing Green	Standby rail and main output off
	Off	Error or no AC power input
Power Supply Fail	Amber	Main output or fan error detected
	Flashing Amber	Power supply warning event detected
	Off	No errors or no power
Power Supply Input	Green	Input voltage within normal range
	Flashing Green	Over or under voltage warning
	Off	No input power
Power Supply Output	Green	Output voltage normal
	Flashing Green	Standby mode
	Amber	Critical error
	Flashing Amber	Warning
	Off	No output
Fan	Green	Fan(s) operating normally
	Flashing Green	Fan switching/initialization in progress
	Amber	Fan failure
	Red	Fan error, RPM too low or too high, or both fan sets have at least one alert
	Flashing Red	One fan set has at least one alert
	Off	Fan error or fan is off

Port LEDs

LED	State	Description
Ethernet	Green	Connected at 1 Gbps
	Flashing Green	Transmitting and receiving data at 1 Gbps
	Amber	Connected at 10/100 Mbps
	Flashing Amber	Transmitting and receiving data at 10/100 Mbps
	Off	No link established

LED	State	Description
Ethernet Link/Activity	Green	Connected
	Flashing Green	Transmitting data
	Off	No link established
Ethernet Speed	Green	Connected at 1 Gbps
	Amber	Connected at 100 Mbps
	Off	Not connected or connected at 10 Mbps
Ethernet 10G Link/Activity	Green	Connected
	Flashing Green	Transmitting data
	Off	No link established
Ethernet 10G Speed	Green	Connected at 10 Gbps
	Amber	Connected at 5 Gbps, 2.5 Gbps, or 1 Gbps
	Off	Not connected or connected at 100 Mbps
PoE	Green	PoE power on or PoE device receiving power
	Amber	Providing power
	Red	Connected but not powered
	Off	PoE power off or no device receiving power
SFP	Green	Connected at 1 Gbps
	Flashing Green	Data activity
	Off	No link established
SFP+	Green	Connected at 10 Gbps or 1 Gbps
	Flashing Green	Data activity
	Off	No link established
SFP28	Green	Connected at 25 Gbps, 10 Gbps, or 1 Gbps
	Flashing Green	Data activity
	Off	No link established
QSFP28	Green	Connected at 100 Gbps or 40 Gbps
	Flashing Green	Data activity
	Off	No link established

Alarm levels

Minor alarm

Also called an IPMI non-critical (NC) alarm, it indicates a temperature or power level outside of the normal operating range that is not considered a problem. For a minor temperature alarm, the system could respond by increasing the fan speed. A non-critical threshold can be an upper non-critical (UNC) threshold (for example, a high temperature or a high power level) or a lower non-critical (LNC) threshold (for example, a low power level).

Major alarm

Also called an IPMI critical or critical recoverable (CR) alarm, it indicates that the system is unable to correct the cause of the alarm, and that intervention is required. For example, the cooling system cannot provide enough cooling to reduce the temperature. It can also mean that the conditions are approaching the outside limit of the allowed operating range. A critical threshold can also be an upper critical (UC) threshold (such as a high temperature or high power level) or a lower critical (LC) threshold (such as a low power level).

Critical alarm

Also called an IPMI non-recoverable (NR) alarm, it indicates that the system has detected a temperature or power level that is outside of the allowed operating range and physical damage is possible.

Troubleshooting your installation

If your FortiGate does not function as desired after installation, try the following troubleshooting tips:

1. Check for equipment issues

Verify that all network equipment is powered on and operating as expected. Refer to the QuickStart Guide for information about connecting your FortiGate to the network.

2. Check the physical network connections

Check the cables used for all physical connections to ensure that they are fully connected and do not appear damaged, and make sure that each cable connects to the correct device and the correct Ethernet port on that device.

3. Verify that you can connect to the internal IP address of the FortiGate

Connect to the GUI from the FortiGate's internal interface by browsing to its IP address. From the PC, try to ping the internal interface IP address; for example, `ping 192.168.1.99`. If you cannot connect to the internal interface, verify the IP configuration of the PC. If you can ping the interface but can't connect to the GUI, check the settings for administrative access on that interface. Alternatively, use SSH to connect to the CLI, and then confirm that HTTPS has been enabled for Administrative Access on the interface.

4. Check the FortiGate interface configurations

Check the configuration of the FortiGate interface connected to the internal network (under *Network > Interfaces*) and check that *Addressing mode* is set to the correct mode.

5. Verify the security policy configuration

Go to *Policy & Objects > Firewall Policy* and verify that the internal interface to Internet-facing interface security policy has been added and is located near the top of the policy list. Check the *Active Sessions* column to ensure that traffic has been processed (if this column does not appear, right-click on the table header and select *Active*).

Sessions). If you are using NAT mode, check the configuration of the policy to make sure that *NAT* is enabled and that *Use Outgoing Interface Address* is selected.

6. Verify the static routing configuration

Go to *Network > Static Routes* and verify that the default route is correct. Go to *Monitor > Routing Monitor* and verify that the default route appears in the list as a static route. Along with the default route, you should see two routes shown as *Connected*, one for each connected FortiGate interface.

7. Verify that you can connect to the Internet-facing interface's IP address

Ping the IP address of the Internet-facing interface of your FortiGate. If you cannot connect to the interface, the FortiGate is not allowing sessions from the internal interface to Internet-facing interface. Verify that PING has been enabled for *Administrative Access* on the interface.

8. Verify that you can connect to the gateway provided by your ISP

Ping the default gateway IP address from a PC on the internal network. If you cannot reach the gateway, contact your ISP to verify that you are using the correct gateway.

9. Verify that you can communicate from the FortiGate to the Internet

Access the FortiGate CLI and use the command `execute ping 8.8.8.8`. You can also use the `execute traceroute 8.8.8.8` command to troubleshoot connectivity to the Internet.

10. Verify the DNS configurations of the FortiGate and the PCs

Check for DNS errors by pinging or using traceroute to connect to a domain name; for example: `ping www.fortinet.com`.

If the name cannot be resolved, the FortiGate or PC cannot connect to a DNS server and you should confirm that the DNS server IP addresses are present and correct.

11. Confirm that the FortiGate can connect to the FortiGuard network

Once the FortiGate is on your network, you should confirm that it can reach the FortiGuard network. First, check the *Licenses* widget to make sure that the status of all FortiGuard services matches the services that you have purchased. Go to *System > FortiGuard*, and, in the Filtering section, click *Test Connectivity*. After a minute, the GUI should indicate a successful connection. Verify that your FortiGate can resolve and reach FortiGuard at `service.fortiguard.net` by pinging the domain name. If you can reach this service, you can then verify the connection to FortiGuard servers by running the command `diagnose debug rating`. This displays a list of FortiGuard IP gateways you can connect to, as well as the following information:

- **Weight:** Based on the difference in time zone between the FortiGate and this server
- **RTT:** Return trip time
- **Flags:** D (IP returned from DNS), I (Contract server contacted), T (being timed), F (failed)
- **TZ:** Server time zone
- **Curr Lost:** Current number of consecutive lost packets
- **Total Lost:** Total number of lost packets

12. Consider changing the MAC address of your external interface

Some ISPs do not want the MAC address of the device connecting to their network cable to change. If you have added a FortiGate to your network, you may have to change the MAC address of the Internet-facing interface using the following CLI command:

```
config system interface
  edit <interface>
    set macaddr <xx:xx:xx:xx:xx:xx>
  end
end
```

13. Check the FortiGate bridge table (transparent mode)

When a FortiGate is in transparent mode, the unit acts like a bridge sending all incoming traffic out on the other interfaces. The bridge is between interfaces on the FortiGate unit. Each bridge listed is a link between interfaces. Where traffic is flowing between interfaces, you expect to find bridges listed. If you are having connectivity issues

and there are no bridges listed, that is a likely cause. Check for the MAC address of the interface or device in question. To list the existing bridge instances on the FortiGate, use the following CLI command:

```
diagnose netlink brctl name host root.b
show bridge control interface root.b host.
fdb: size=2048, used=25, num=25, depth=1
Bridge root.b host table
port no device devname mac addr ttl attributes
3 4 wan1 00:09:0f:cb:c2:77 88
3 4 wan1 00:26:2d:24:b7:d3 0
3 4 wan1 00:13:72:38:72:21 98
4 3 internal 00:1a:a0:2f:bc:c6 6
1 6 dmz 00:09:0f:dc:90:69 0 Local Static
3 4 wan1 c4:2c:03:0d:3a:38 81
3 4 wan1 00:09:0f:15:05:46 89
3 4 wan1 c4:2c:03:1d:1b:10 0
2 5 wan2 00:09:0f:dc:90:68 0 Local Static
```

14. Use FortiExplorer if you cannot connect to the FortiGate over Ethernet

If you cannot connect to the FortiGate GUI or CLI, you may be able to connect using FortiExplorer. Refer to the QuickStart Guide or see the section on FortiExplorer for more details.

15. Either reset the FortiGate to factory defaults or contact Fortinet Support for assistance

To reset the FortiGate to factory defaults, use the CLI command `execute factoryreset`. When prompted, type `y` to confirm the reset.

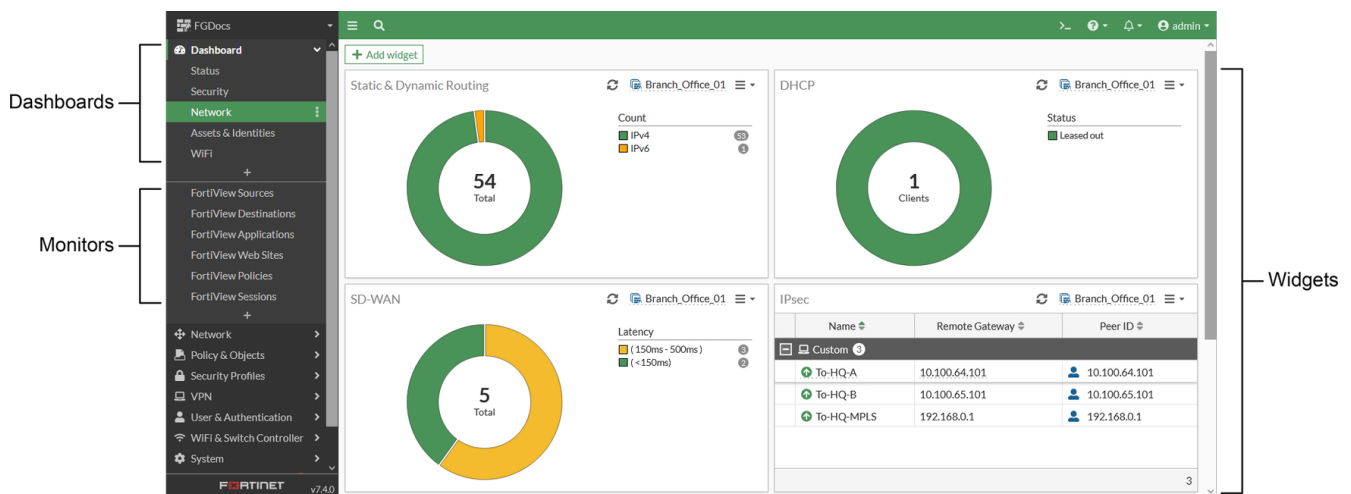

If you require further assistance, visit the [Fortinet Support](#) website.

Dashboards and Monitors

FortiOS includes predefined dashboards so administrators can easily monitor device inventory, security threats, traffic, and network health. You can customize the appearance of a default dashboard to display data pertinent to your Security Fabric or combine widgets to create custom dashboards. Many dashboards also allow you to switch views between Fabric devices.

Each dashboard contains a set of widgets that allow you to view drilldown data and take actions to prevent threats. Use widgets to perform tasks such as viewing device inventory, creating and deleting DHCP reservations, and disconnecting dial-up users. You can add or remove widgets in a dashboard or save a widget as a standalone monitor.

Monitors display information in both text and visual format. Use monitors to change views, search for items, view drilldown information, or perform actions such as quarantining an IP address. FortiView monitors for the top categories are located below the dashboards. All of the available widgets can be added to the tree menu as a monitor.

Using dashboards

You can combine widgets to create custom dashboards. You can also use the dropdown in the tree menu to switch to another device in the Security Fabric.

To create a new dashboard:

1. Under *Dashboard*, click the *Add Dashboard* button. The *Add Dashboard* window opens.

2. Enter a name in the *Name* field and click *OK*. The new dashboard opens.

To add a widget to a dashboard:

1. In the tree menu, select a dashboard.
2. In the banner, click *Add Widget*. The *Add Dashboard Widget* pane opens.
3. Click the *Add* button next to the widget. You can use the *Search* field to search for a widget. Enable *Show More* to view more widgets in a category.
4. Configure the widget settings, then click *Add Widget*.
5. Click *Close*.
6. (Optional) Click and drag the widget to the desired location in the dashboard.

To edit a dashboard:

1. Click the *Actions* menu next to the dashboard and select *Edit Dashboard*.

2. Edit the dashboard and click *OK*.

To delete a dashboard:

1. Click the *Actions* menu next to the dashboard and select *Delete Dashboard*.

2. Click *Delete Dashboard*. The *Confirm* dialog opens.
3. Click *OK*.

You cannot delete the *Status* dashboard.

To switch to another device in the Security Fabric:

1. In the tree menu, click the device name and select a Fabric device from dropdown.

Using widgets

You can convert a widget to a standalone monitor, change the view type, configure tables, and filter data.

To save a dashboard widget as a monitor:

1. Hover over the widget and click *Expand to full screen*.

Full screen mode is not supported in all widgets.

2. In the widget, click *Save as Monitor*. The *Add Monitor* window opens.

3. (Optional) Enter a new name for the monitor in the *Name* field.
4. Click *OK*.

To view the widget settings:

1. Click the menu dropdown at the right side of the widget and select *Settings*.

2. Configure the widget settings and click *OK*.

The settings will vary depending on the widget.

To configure a table in the widget:

1. Hover over the left side of the table header and click *Configure Table*.

2. Configure the table options:

Option	Description
Best Fit All Columns	Resizes all of the columns in a table to fit their content.
Reset Table	Resets the table to the default view.
Select Columns	Adds or removes columns from the view.

3. Click *Apply*.

To filter or configure a column in a table:

1. Hover over a column heading, and click *Filter/Configure Column*.

2. Configure the column options.

Option	Description
Resize to Contents	Resizes the column to fit the content.
Group by this Column	Groups the table rows by the contents in the selected column.

3. Click *Apply*.
4. To filter a column, enter a value in the *Filter* field, and click *Apply*.

Filtering is not supported in all widgets.

Widgets

Dashboards are created per VDOM when VDOM mode is enabled. For information about VDOM mode, see [Virtual Domains on page 2475](#).

Some dashboards and widgets are not available in Multi-VDOM mode.

The following table lists the available widgets in VDOM mode:

Category	Widgets
FortiView	<ul style="list-style-type: none"> • FortiView Application Bandwidth • FortiView Applications • FortiView Cloud Applications • FortiView Destination Interfaces • FortiView Destination Owners • FortiView Destinations • FortiView Policies • FortiView Proxy Destinations • FortiView Proxy Policies • FortiView Proxy Sessions • FortiView Proxy Sources • FortiView Sessions • FortiView Source Interfaces • FortiView Sources • FortiView VPN • FortiView Web Categories • FortiView Web Sites • FortiView ZTNA Servers • FortiView Countries/Regions • FortiView Destination Firewall Objects • FortiView Interface Pairs • FortiView Search Phrases • FortiView Servers • FortiView Source Firewall Objects • FortiView Sources - WAN • FortiView Traffic Shaping
Security Fabric	<ul style="list-style-type: none"> • FortiGate Cloud • Security Fabric Status
Network	<ul style="list-style-type: none"> • DHCP • DNS • Interface Bandwidth • IP Pool Utilization • IPsec • Load Balance • Routing • SD-WAN • SSL-VPN • Top IP Pools by Assigned IPs

Category	Widgets
	 <p>The <i>Interface Bandwidth</i> widget can monitor a maximum of 25 interfaces.</p>
System	<ul style="list-style-type: none"> • Administrators • Botnet Activity • HA Status • License Status • System Information • Top System Events • Virtual Machine
Resource Usage	<ul style="list-style-type: none"> • CPU Usage • Disk Usage • Log Rate • Logs Sent • Memory Usage • Session Rate • Sessions
Security	<ul style="list-style-type: none"> • Advanced Threat Protection Statistics • Assets - Vulnerabilities • Compromised Hosts • FortiSandbox Files • Quarantine • Top Endpoint Vulnerabilities • Top Failed Authentication • Top Threats • Top Threats - WAN
User & Authentication	<ul style="list-style-type: none"> • Assets • Assets - FortiClient • Firewall Users • FortiGuard Quota • Identities • Matched NAC Devices • Top Admin Logins • Top Cloud Users
WiFi	<ul style="list-style-type: none"> • Channel Utilization • Clients By FortiAP • FortiAP Status

Category	Widgets
	<ul style="list-style-type: none"> • Historical Clients • Interfering SSIDs • Login Failures • Rogue APs • Signal Strength • Top WiFi Clients

Viewing device dashboards in the Security Fabric

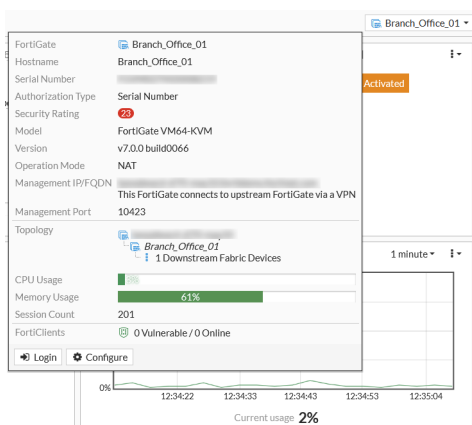

Use the device dropdown to view the dashboards in downstream Fabric devices. You can also create dedicated device dashboards or log in and configure Fabric devices.

To view the dashboards in Fabric devices, click the device dropdown at the left side of the page, and select a device from the list.

The device dropdown is available in the *Status*, *Security*, *Network*, *Assets & Identities*, and *WiFi* dashboards. You can also enable the dropdown when you create a dashboard.

To log in to or configure a Fabric device, hover over the device name until the device dialog opens and then select *Login* or *Configure*.

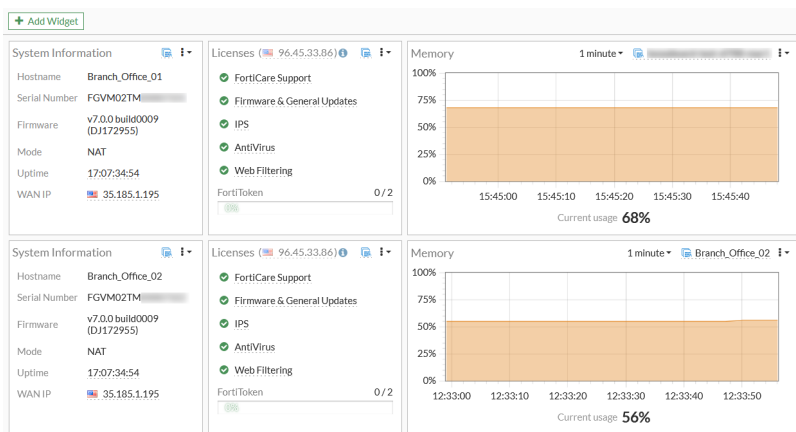

Creating a fabric system and license dashboard

Create a dashboard summary page to monitor all the Fabric devices in a single view. You can use this dashboard to monitor aspects of the devices such as system information, VPN and routing.

Example

The following image is an example of a *Fabric System & License* dashboard to monitor the *System Information*, *Licenses*, and *Memory* usage for *Branch_Office_01* and *Branch_Office_02*.

To create a system dashboard:

1. Click the **Add Dashboard** button. The **Add Dashboard** window opens.

2. In the **Name** field, enter a name such as *Fabric System & Licenses*, and click **OK**. The new dashboard appears.
3. In the banner, click **Add Widget**. The **Add Dashboard Widget** window opens. You can use the **Search** field to search for a specific widget (for example, *License Status*, *System Information*, and *Memory Usage*).
4. Click the **Add** button next to widget. The **Add Dashboard Widget** window opens.
5. In the **Fabric member** area, select **Specify** and select a device in the Security Fabric.

6. Click **Add Widget**. The widget is added to the dashboard.
Repeat this step for all the devices you want to view in the dashboard.
7. (Optional) Arrange the widgets in the dashboard by Fabric device.

Dashboards

A dashboard is a collection of widgets that show the status of your devices, network, and Security Fabric at a glance. Widgets are condensed monitors that display a summary of the key details about your FortiGate pertaining to routing, VPN, DHCP, devices, users, quarantine, and wireless connections.

The following dashboards are included in the dashboard templates:

Dashboard	Default Template	Use these widgets to:
Status	<ul style="list-style-type: none"> Comprehensive Optimal 	<ul style="list-style-type: none"> View the device serial number, licenses, and administrators View the status of devices in the security fabric Monitor CPU and Memory usage Monitor IPv4 and IPv6 sessions View VMs and Cloud devices
Security	<ul style="list-style-type: none"> Optimal 	<ul style="list-style-type: none"> View compromised hosts and host scan summary View top threats and vulnerabilities
Network	<ul style="list-style-type: none"> Optimal 	<ul style="list-style-type: none"> Monitor DHCP clients Monitor IPsec VPN connections Monitor current routing table Monitor SD-WAN status Monitor SSL-VPN connections
Assets & Identities	<ul style="list-style-type: none"> Optimal 	<ul style="list-style-type: none"> View users and devices connected to the network Identify threats from individual users and devices View FortiGuard and FortiClient data Monitor traffic bandwidth over time
WiFi	<ul style="list-style-type: none"> Comprehensive Optimal 	<ul style="list-style-type: none"> View FortiAP status, channel utilization, and clients View login failures and signal strength View the number of WiFi clients

Resetting the default dashboard template

You can use the GUI to change the default dashboard template. The *Optimal* template contains a set of popular default dashboards and FortiView monitors. The *Comprehensive* template contains a set of default dashboards as well as all of the FortiView monitors.

Resetting the default template will delete any custom dashboards and monitors, and reset the widget settings.

To reset all dashboards:

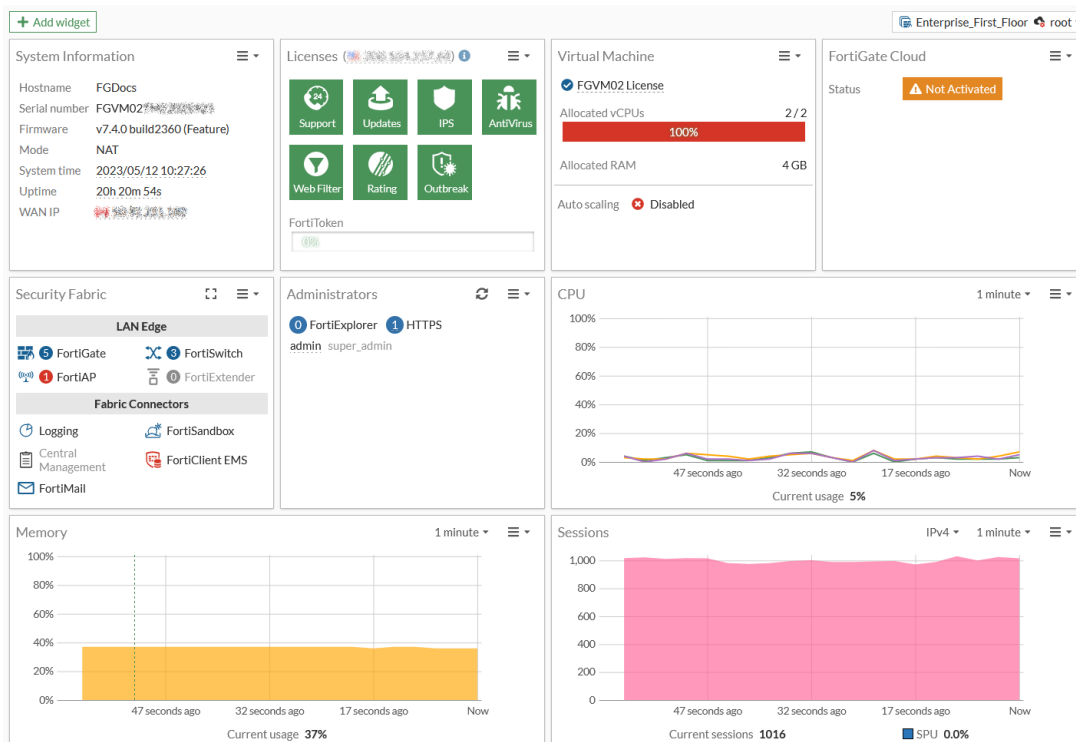

1. Click the *Actions* menu next to *Add Dashboard* or *Add Monitor* and click *Reset All Dashboards*. The *Dashboard Setup* window opens.

2. Select *Optimal* or *Comprehensive* and click *OK*.

Status dashboard

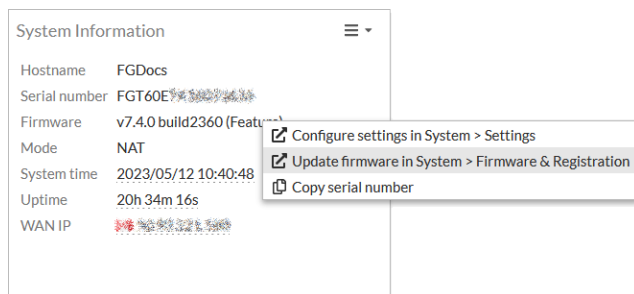

The *Status* dashboard provides an overview of your FortiGate device and the devices in your Security Fabric. If your FortiGate is a virtual machine, information about the virtual machine is also displayed in the dashboard.

Updating system information

The *System Information* widget contains links to the *Settings* module where you can update the *System Time*, *Uptime*, and *WAN IP*.

A notification will appear in the *Firmware* field when a new version of FortiOS is released. Click *Update firmware in System > Firmware & Registration* to view the available versions and update FortiOS.

Viewing Fabric devices

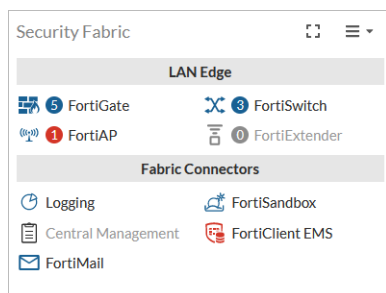

The *Security Fabric* widget provides a visual overview of the devices connected to the Fabric and their connection status. Hover of a device icon to view more information about the device.

Click a device in the Fabric to:

- View the device in the physical or logical topology
- Register, configure, deauthorize, or log in to the device
- Open *Diagnostics and Tools*
- View the *FortiClient Monitor*

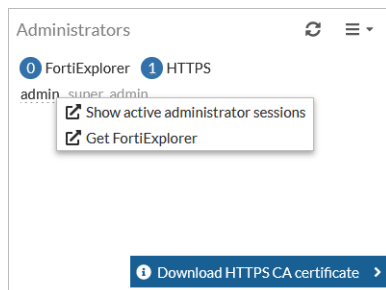

These options will vary depending on the device.

Click *Expand & Pin hidden content* to view all the devices in the Fabric at once.

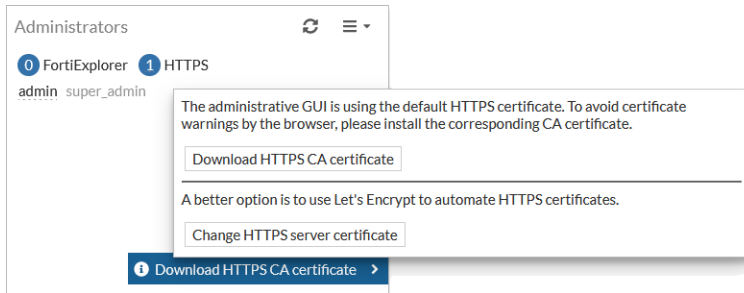

Viewing administrators

The *Administrators* widget displays the active administrators and their access interface. Click the username to view the *Active Administrator Sessions* monitor. You can use the monitor to end an administrator's session.

If the GUI is using the default HTTPS certificate, a warning is shown where you can download the HTTPS CA certificate or change the HTTPS server certificate.

Viewing logs sent for remote logging source

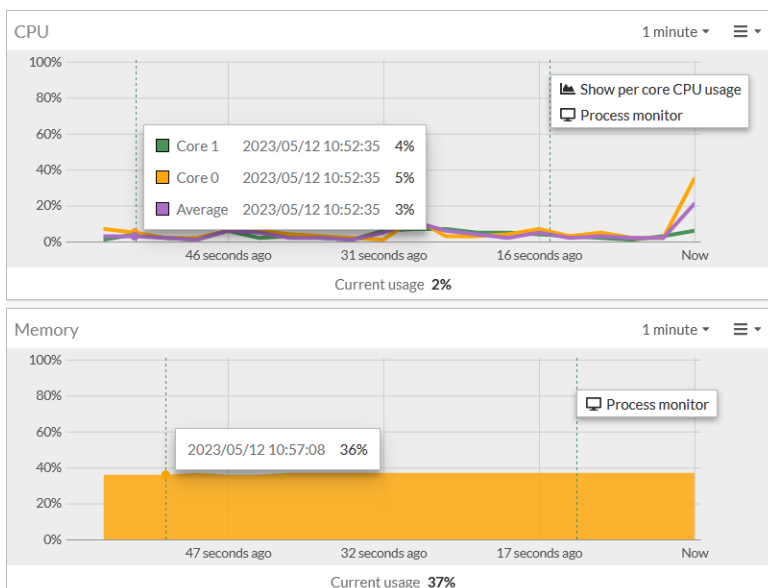

The *Logs Sent* widget displays chart for remote logging sources (FortiAnalyzer, FortiGate Cloud, and FortiAnalyzer Cloud) sent daily.

Resource widgets

The resource widgets show the current usage statistics for *CPU*, *Memory*, and *Sessions*.

Click the *CPU* monitor to show the per core CPU usage.

You can switch between *IPv4*, *IPv6*, or *IPv4+IPv6* in the *Sessions* monitor.

Security dashboard

The widgets in the *Security* dashboard provide a snapshot of the current threats and vulnerabilities targeting your Security Fabric.

The *Security* dashboard contains the following widgets:

Widget	Description
Compromised Hosts by Verdict	Shows the session information for a compromised host. See Viewing session information for a compromised host on page 113 .
Top Threats by Threat Level	Shows the top traffic sessions aggregated by threat. You can expand the widget to view drilldown information about the <i>Threat</i> , <i>Threat Category</i> , <i>Threat Level</i> , <i>Threat Score</i> and <i>Sessions</i> .
Assets - Vulnerabilities	Shows a summary of asset vulnerabilities.

Viewing session information for a compromised host

You can use the *Compromised Hosts by Verdict* widget to view the session information for a compromised host.

To view session information for a compromised host in the GUI:

1. Go to *Dashboard > Security* and expand the *Compromised Hosts by Verdict* widget.

Network dashboard

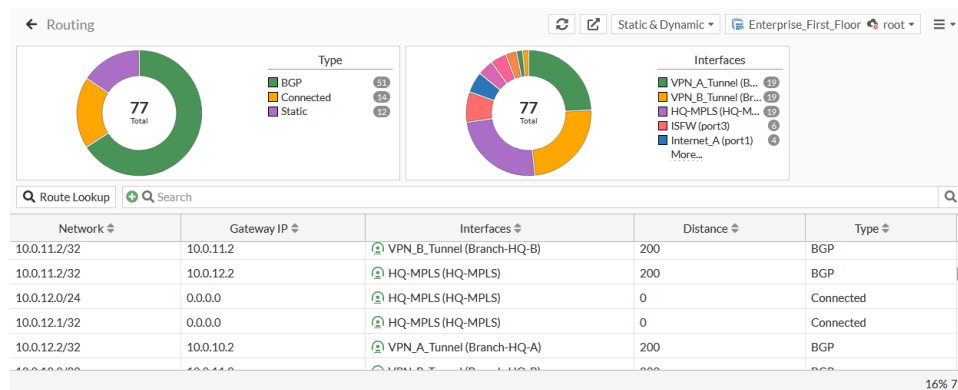

The widgets in the Network dashboard show information related to networking for this FortiGate and other devices connected to your Security Fabric. Use this dashboard to monitor the status of Routing, DHCP, SD-WAN, IPsec and SSL VPN tunnels. All of the widgets in the *Network* dashboard can be expanded to full screen and saved as a monitor.

The *Network* dashboard contains the following widgets:

Widget	Description
Static & Dynamic Routing	Shows the static and dynamic routes currently active in your routing table. The widget also includes policy routes, BGP neighbors and paths, and OSPF neighbors. See Static & Dynamic Routing monitor on page 115 .
DHCP	Shows the addresses leased out by FortiGate's DHCP servers. See DHCP monitor on page 118 .
SD-WAN	Shows a summary of the SD-WAN status, including ADVPN shortcut information.
IPsec	Shows the connection statuses of your IPsec VPN site to site and dial-up tunnels. See IPsec monitor on page 119 .
SSL-VPN	Shows a summary of remote active users and the connection mode. See SSL-VPN monitor on page 121 .
IP Pool Utilization	Shows IP pool utilization.

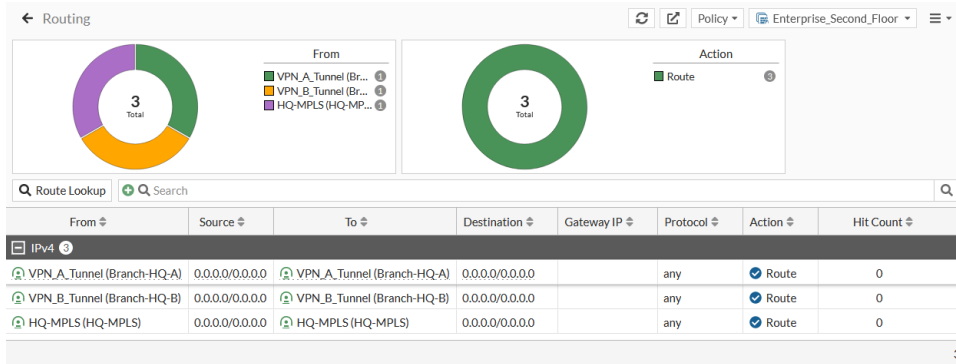

Static & Dynamic Routing monitor

The *Static & Dynamic Routing* monitor displays the routing table on the FortiGate, including all static and dynamic routing protocols in IPv4 and IPv6. You can also use this monitor to view policy routes, BGP neighbors and paths, and OSPF neighbors.

To view the routing monitor in the GUI:

1. Go to *Dashboard > Network*.
2. Hover over the *Routing* widget, and click *Expand to Full Screen*. The *Routing* monitor is displayed.
3. To view policy routes, click the monitors dropdown at the top of the page and select *Policy*.

4. To view neighbors and paths, click the monitors dropdown and select the required neighbor or path type.

For example:

- **BGP Neighbors**

Neighbor IP	Local IP	Remote AS	State	Admin Status
10.0.10.2	10.0.10.1	65000	Established	Enabled
10.0.10.3	10.0.10.1	65000	Established	Enabled
10.0.11.2	10.0.11.1	65000	Established	Enabled
10.0.11.3	10.0.11.1	65000	Established	Enabled
10.0.12.2	10.0.12.1	65000	Established	Enabled
10.0.12.3	10.0.12.1	65000	Established	Enabled

- **BGP Paths**

Prefix	Learned From	Next Hop	Origin	Best Path
10.0.10.2/32	10.0.10.2	10.0.10.2	Incomplete	Yes
10.0.11.2/32	10.0.11.2	10.0.11.2	Incomplete	Yes
10.0.11.2/32	10.0.12.2	10.0.12.2	Incomplete	Yes
10.0.11.2/32	10.0.10.2	10.0.10.2	Incomplete	Yes
10.0.12.2/32	10.0.11.2	10.0.11.2	Incomplete	Yes
10.0.12.2/32	10.0.12.2	10.0.12.2	Incomplete	Yes
10.0.12.2/32	10.0.10.2	10.0.10.2	Incomplete	Yes
10.0.10.2/24	10.0.11.2	10.0.11.2	Incomplete	Yes

5. To filter a column:

a. Hover over the column heading, and click the *Filter/Configure Column* icon.

- b. Configure the filter, then click *Apply*.

6. (Optional) Click the *Save as Monitor* button to save the widget as monitor.

To look up a route in the GUI:

1. Click *Route Lookup*.

2. Enter an IP address in the *Destination* field.
3. Configure the remaining options as needed, then click *OK*.

The matching route is highlighted on the *Routing* monitor.

To view the routing table in the CLI:

```
# get route info routing-table all
```

Sample output:

```
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default
```

```
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 10.0.10.1, To-HQ-A
[1/0] via 10.0.12.1, To-HQ-MPLS
[1/0] via 10.10.11.1, To-HQ-B
[1/0] via 10.100.67.1, port1
[1/0] via 10.100.67.9, port2
C       10.0.10.0/24 is directly connected, To-HQ-A
C       10.0.10.2/32 is directly connected, To-HQ-A
C       10.0.11.0/24 is directly connected, To-HQ-B
C       10.0.11.2/32 is directly connected, To-HQ-B
C       10.0.12.0/24 is directly connected, To-HQ-MPLS
```

```

C      10.0.12.2/32 is directly connected, To-HQ-MPLS
C      10.1.0.0/24 is directly connected, port3
C      10.1.0.2/32 is directly connected, port3
C      10.1.0.3/32 is directly connected, port3
C      10.1.100.0/24 is directly connected, vsw.port6

```

To look up a firewall route in the CLI:

```
# diagnose firewall proute list
```

Sample output:

```
list route policy info(vf=root):
```

```

id=1(0x01) dscp_tag=0xfc 0xfc flags=0x0 tos=0x00 tos_mask=0x00 protocol=0 sport=0-0 iif=15

```

DHCP monitor

The DHCP monitor shows all the addresses leased out by FortiGate's DHCP servers. You can use the monitor to revoke an address for a device, or create, edit, and delete address reservations.

To view the DHCP monitor:

1. Go to *Dashboard > Network*.
2. Hover over the *DHCP* widget, and click *Expand to Full Screen*.

To filter or configure a column in the table, hover over the column heading and click the *Filter/Configure Column* button.

To revoke a lease:

1. Select a device in the table.
2. In the toolbar, click *Revoke*, or right-click the device, and click *Revoke Lease(s)*. The *Confirm* page is displayed.
3. Click *OK*.

A confirmation window opens only if there is an associated address reservation. If there is no address, the lease will be removed immediately upon clicking *Revoke*.

To create a DHCP reservation:

1. Select a server in the table.
2. In the toolbar, click *Reservation > Create DHCP Reservation*, or right-click the device and click *Create DHCP Reservation*. The *Create New DHCP Reservation* page is displayed.
3. Configure the DHCP reservation settings.

4. Click *OK*.

To view top sources by bytes:

1. Right-click a device in the table and click *Show in FortiView*. The *FortiView Sources by Bytes* widget is displayed.

To view the DHCP lease list in the CLI:

```
# execute dhcp lease-list
```

IPsec monitor

The IPsec monitor displays all connected Site to Site VPN, Dial-up VPNs, and ADVPN shortcut tunnel information. You can use the monitor to bring a phase 2 tunnel up or down or disconnect dial-up users. A notification appears in the monitor when users have not enabled two-factor authentication.

Name	Remote Gateway	Peer ID	Incoming Data	Outgoing Data	Phase 1	Phase 2 Selectors
Branch-HQ-A_0	10.100.68.5	10.100.68.5	156.71 MB	25.8 MB	Branch-HQ-A_0	Branch-HQ-A
Branch-HQ-A_1	10.100.67.5	10.100.67.5	58.68 MB	45.87 MB	Branch-HQ-A_1	Branch-HQ-A
Branch-HQ-B_0	10.100.68.13	10.100.68.13	41.07 MB	31.89 MB	Branch-HQ-B_0	Branch-HQ-B
Branch-HQ-B_1	10.100.67.13	10.100.67.13	184.52 MB	40.52 MB	Branch-HQ-B_1	Branch-HQ-B
HQ-MPLS_0	192.168.0.14	192.168.0.14	63.54 MB	63.82 MB	HQ-MPLS_0	HQ-MPLS
HQ-MPLS_1	192.168.1.14	192.168.1.14	62.47 MB	62.67 MB	HQ-MPLS_1	HQ-MPLS

To view the IPsec monitor in the GUI:

1. Go to *Dashboard > Network*.
2. Hover over the *IPsec* widget, and click *Expand to Full Screen*. A warning appears when an unauthenticated user is detected.

To filter or configure a column in the table, hover over the column heading and click the *Filter/Configure Column* button.

3. Hover over a record in the table. A tooltip displays the *Phase 1* and *Phase 2* interfaces. A warning appears next to a user who has not enabled two-factor authentication.

To reset statistics:

1. Select a tunnel in the table.
2. In the toolbar, click *Reset Statistics* or right-click the tunnel, and click *Reset Statistics*. The *Confirm* dialog is displayed.
3. Click *OK*.

To bring a tunnel up:

1. Select a tunnel in the table.
2. Click *Bring Up*, or right-click the tunnel, and click *Bring Up*. The *Confirm* dialog is displayed.
3. Click *OK*.

To bring a tunnel down:

1. Select a tunnel in the table.
2. Click *Bring Down*, or right-click the tunnel, and click *Bring Down*. The *Confirm* dialog is displayed.
3. Click *OK*.

To locate a tunnel on the VPN Map:

1. Select a tunnel in the table.
2. Click *Locate on VPN Map*, or right-click the tunnel, and click *Locate on VPN Map*. The *VPN Location Map* is displayed.

To view the IPsec monitor in the CLI:

```
# diagnose vpn tunnel list
```

Sample output:

```
list all ipsec tunnel in vd 0

SSL-VPN monitor

The SSL-VPN monitor displays remote user logins and active connections. You can use the monitor to disconnect a specific connection. The monitor will notify you when VPN users have not enabled two-factor authentication.

To view the SSL-VPN monitor in the GUI:

1. Go *Dashboard > Network*.
2. Hover over the *SSL-VPN* widget, and click *Expand to Full Screen*. The *Duration* and *Connection Summary* charts are displayed at the top of the monitor.

To filter or configure a column in the table, hover over the column heading and click the *Filter/Configure Column* button.

To disconnect a user:

1. Select a user in the table.
2. In the table, right-click the user, and click *End Session*. The Confirm window opens.
3. Click *OK*.

To monitor SSL-VPN users in the CLI:

```
# get vpn ssl monitor
```

Sample output

SSL VPN Login Users:

```
Index User Group Auth Type Timeout From HTTP in/out HTTPS in/out
0 amitchell TAC 1(1) 296 10.100.64.101 3838502/11077721 0/0
1 mmiles Dev 1(1) 292 10.100.64.101 4302506/11167442 0/0
```

SSL VPN sessions:

```
Index User Group Source IP Duration I/O Bytes Tunnel/Dest IP
```

Assets & Identities

The *Assets & Identities* dashboard shows the current status of users and devices connected to your network. All of the widgets can be expanded to view as monitor. In monitor view, you can create firewall addresses, deauthenticate a user, or remove a device from the network.

The *Assets & Identities* dashboard contains the following widgets:

Widget	Description
Device Inventory	Shows a summary of the hardware and software that is connected to the network. See Device inventory on page 123 .

Widget	Description
FortiClient	Shows a summary of the FortiClient endpoints.
Firewall Users	Monitor users that are logged into the network.
Quarantine	Monitor quarantined devices.
Matched NAC Devices	Monitor VLANs assigned to devices by FortiSwitch NAC policies.

Device inventory

You can enable device detection to allow FortiOS to monitor your networks and gather information about devices operating on those networks, including:

- MAC address
- IP address
- Operating system
- Hostname
- Username
- Endpoint tags
- When FortiOS detected the device and on which interface

You can enable device detection separately on each interface in *Network > Interfaces*.

Device detection is intended for devices directly connected to your LAN and DMZ ports. The widget is only available when your *Interface Role* is *LAN*, *DMZ* or *Undefined*. It is not available when the role is *WAN*.

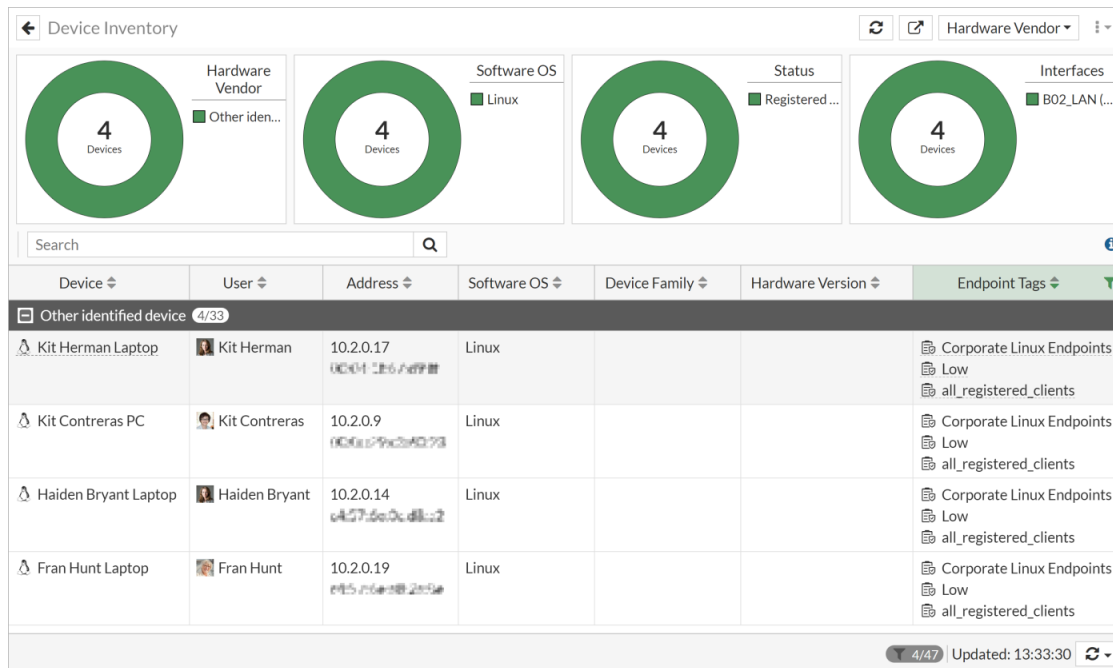

You can also manually add devices to Device Inventory to ensure that a device with multiple interfaces displays as a single device.

To view the device inventory monitor:

1. Go to *Dashboard > Users & Devices*.
If you are using the Comprehensive dashboard template, go to *Dashboard > Device Inventory Monitor*.
2. Hover over the *Device Inventory* widget, and click *Expand to Full Screen*. The *Device Inventory* monitor is displayed.

To filter or configure a column in the table, hover over the column heading, and click *Filter/Configure Column*. See [Device inventory and filtering on page 124](#).

Device inventory and filtering

The *Device Inventory* widget contains a series of summary charts that provide an overview of the hardware, operating system, status, and interfaces. You can use these clickable charts to simplify filtering among your devices.

To view the device inventory and apply a filter:

1. Go to *Dashboard > Users & Devices*.
If you are using the Comprehensive dashboard template, go to *Dashboard > Device Inventory Monitor*. See .
2. Hover over the *Device Inventory* widget, and click *Expand to Full Screen*. The *Device Inventory* monitor is displayed.
3. To filter the order of the charts by operating system, click the dropdown in the top menu bar and select *Software OS*.
4. To filter a chart, click an item in the legend or chart area. The table displays the filter results.
5. To combine filters, hover over a column heading and click *Filter/Configure Column*.

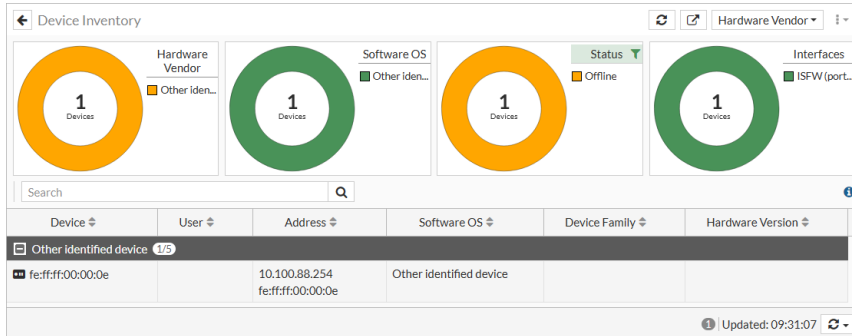

6. Click the filter icon in the top-right corner of the chart to remove the filter.

Filter examples

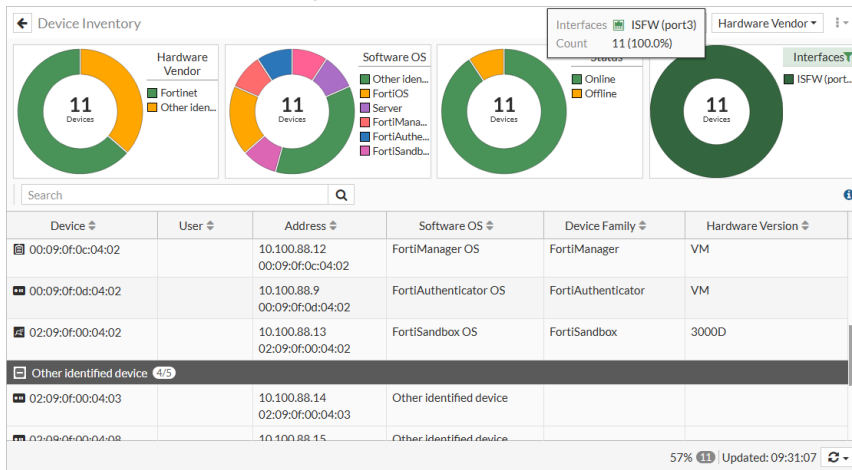

To filter all offline devices:

1. In the *Status* chart, click *Offline* in the legend or on the chart itself.

To filter all devices discovered on port3:

1. In the *Interfaces* chart, click *port3*.

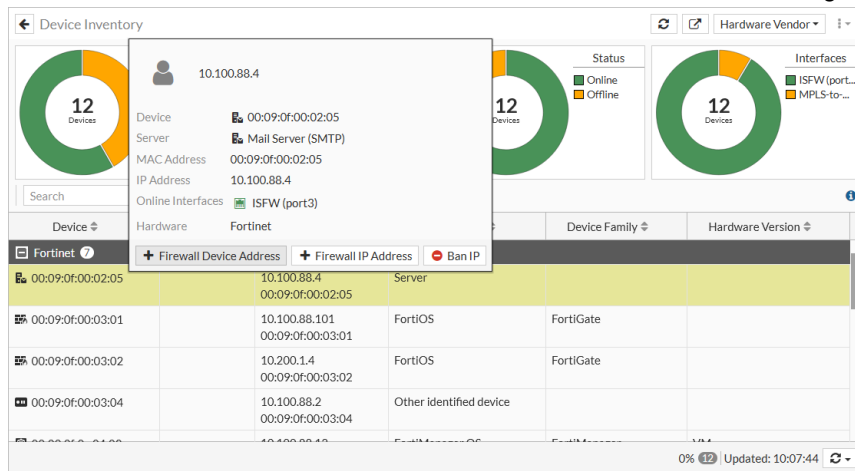

Adding MAC-based addresses to devices

Assets detected by device detection appear in the *Device Inventory* widget. You can manage policies around devices by adding a new device object (MAC-based address) to a device. Once you add the MAC-based address, the device can be used in address groups or directly in policies.

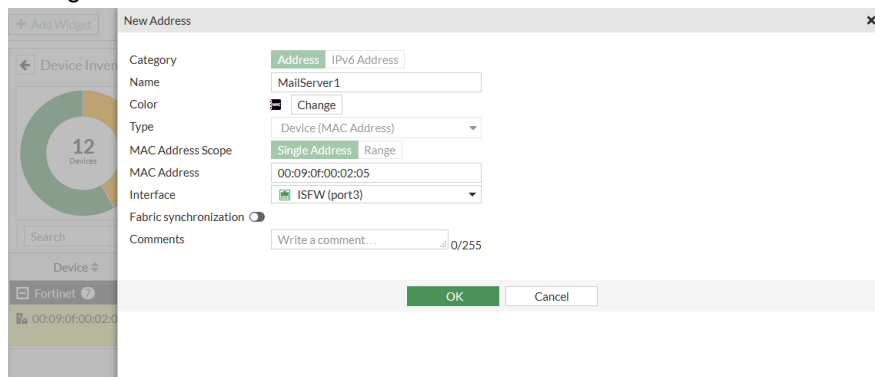

To add a MAC-based address to a device:

1. Go to *Dashboard > Users & Devices*.
If you are using the Comprehensive dashboard template, go to *Dashboard > Device Inventory Monitor*. See .
2. Hover over the *Device Inventory* widget, and click *Expand to Full Screen*. The *Device Inventory* monitor is displayed.

3. Click a device, then click *Firewall Device Address*. The *New Address* dialog is displayed.

4. In the *Name* field, give the device a descriptive name so that it is easy to in the *Device* column.
5. Configure the *MAC Address*.

6. Click *OK*, then refresh the page. The MAC address icon appears in the *Address* column next to the device name.

Firewall Users monitor

The Firewall Users monitor displays all firewall users currently logged in. You can use the monitor to diagnose user-related logons or to highlight and deauthenticate a user.

To view the firewall monitor:

- 1. Go to *Dashboard > Users & Devices*.
If you are using the Comprehensive dashboard template, go to *Dashboard > Firewall User Monitor*. See .
- 2. Hover over the *Firewall Users* widget, and click *Expand to Full Screen*.
- 3. To show FSSO logons, click *Show all FSSO Logons* at the top right of the page.

To filter or configure a column in the table, hover over the column heading and click the *Filter/Configure Column* button.

To deauthenticate a user:

- 1. Go to *Dashboard > Users & Devices*.
- 2. Hover over the *Firewall Users* widget, and click *Expand to Full Screen*.
- 3. (Optional) Use the *Search* field to search for a specific user.
- 4. In the toolbar, click *Deauthenticate*, or right-click the user, and click *Deauthenticate*. The *Confirm* dialog is displayed.
- 5. Click *OK*.

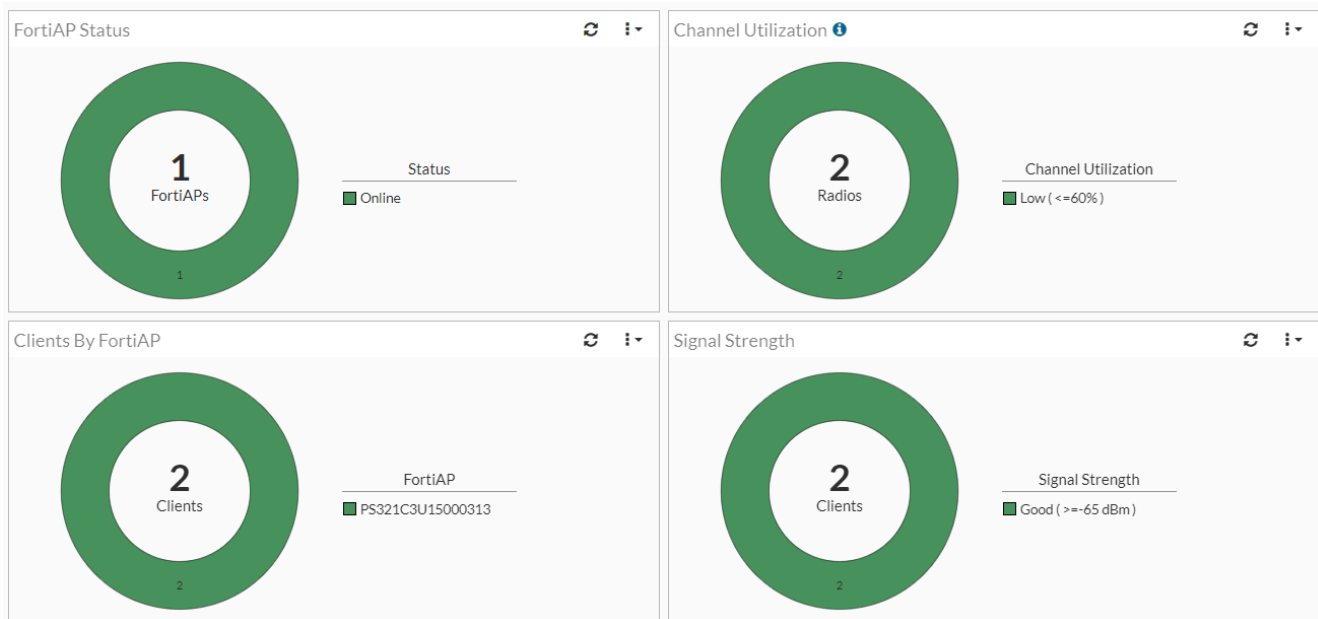

To view firewall users in the CLI:

```
# diagnose firewall auth list
```

WiFi dashboard

The *WiFi* dashboard provides an overview of your WiFi network's performance, including FortiAP status, channel utilization, WiFi clients and associated information, login failures, and signal strength.

To access the WiFi dashboard, go to *Dashboard > WiFi*.

The WiFi dashboard can be customized per your requirements. To learn more about using and modifying dashboards and widgets, see [Dashboards and Monitors on page 101](#).

This section describes the following monitors available for the WiFi Dashboard:

- [FortiAP Status monitor on page 128](#)
- [Clients by FortiAP monitor on page 130](#)

FortiAP Status monitor

The *FortiAP Status* monitor displays the status and the channel utilization of the radios of FortiAP devices connected to a FortiGate. It also provides access to tools to diagnose and analyze connected APs.

To view the *FortiAP Status* monitor:

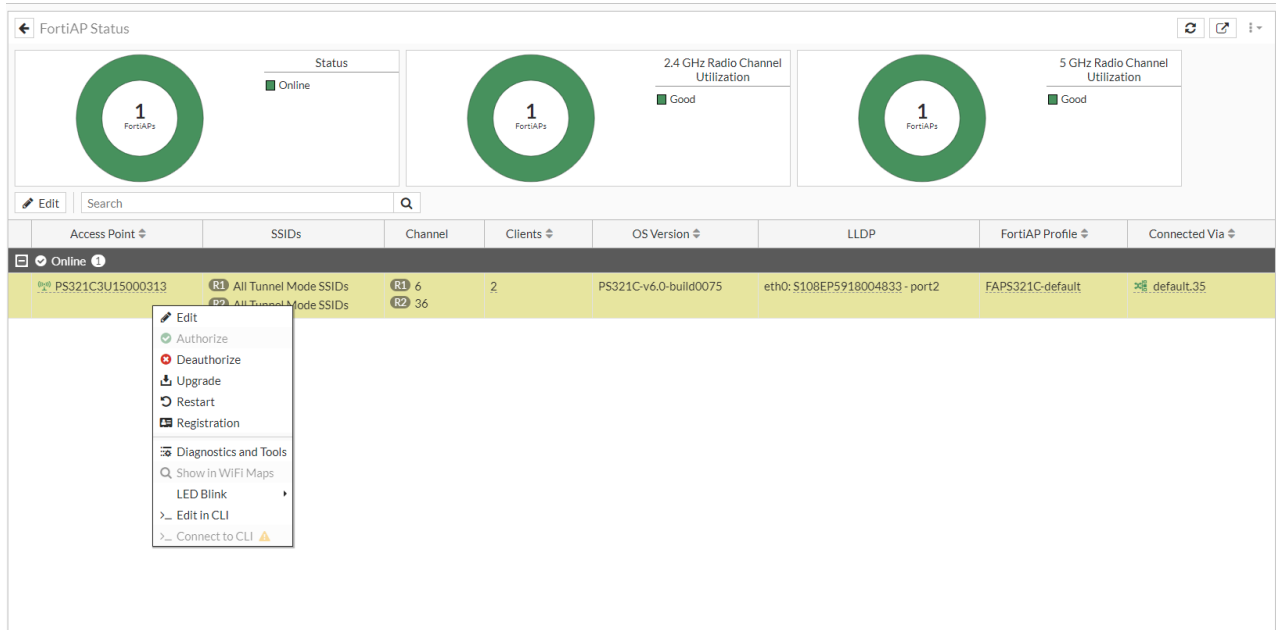

1. Go to *Dashboard > WiFi*.
2. Hover over the *FortiAP Status* widget, and click *Expand to Full Screen*. The *FortiAP Status* monitor opens.

3. (Optional) Click *Save as Monitor* to save the widget as monitor.

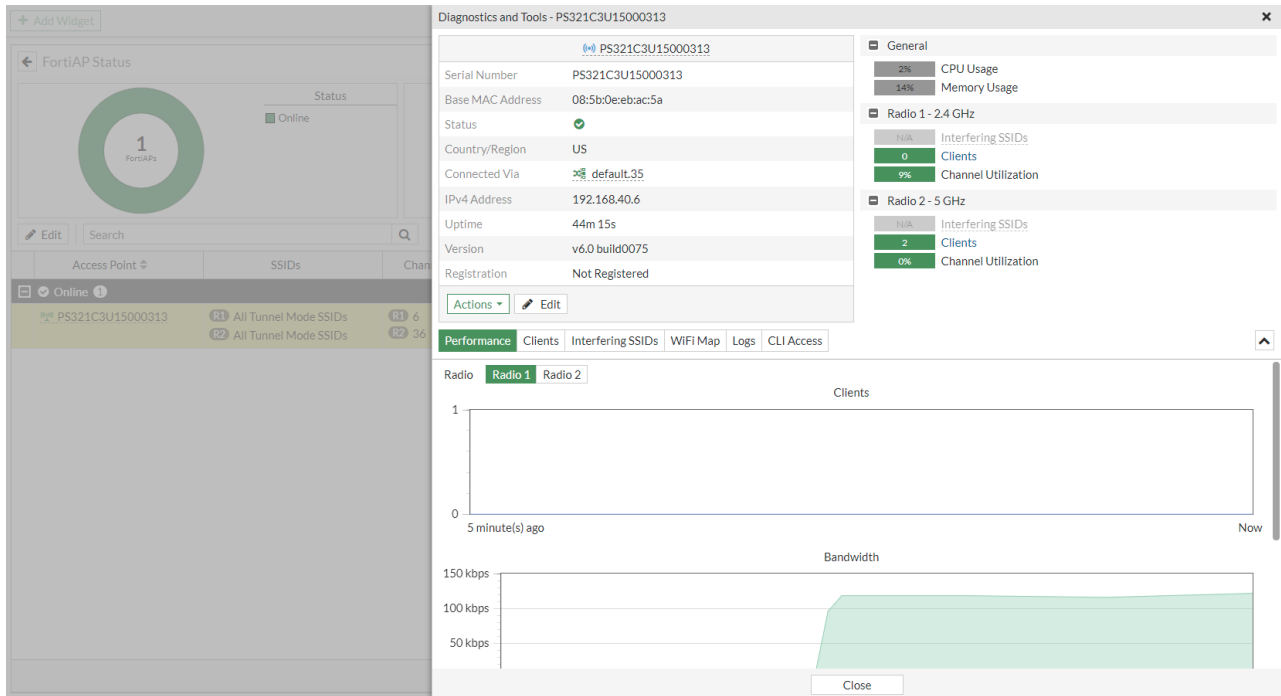

To view the Diagnostics and Tools menu:

1. Right-click an *Access Point* in the table, and click *Diagnostics and Tools*. The *Diagnostics and Tools* dialog opens.

2. To monitor and analyze the FortiAP device, click on the tabs in the *Diagnostics and Tools* dialog, such as *Clients*, *Spectrum Analysis*, *VLAN Probe*, and so on.

The *Diagnostics and Tools* dialog is similar to the device dialog from *WiFi & Switch Controller > Managed FortiAPs*. To learn more about the various tabs and their functions, see [Spectrum analysis of FortiAP E models](#), [VLAN probe report](#), and [Standardize wireless health metrics](#).

Clients by FortiAP monitor

The *Clients by FortiAP* monitor allows you to view detailed information about the health of individual WiFi connections in the network. It also provides access to tools to diagnose and analyze connected wireless devices.

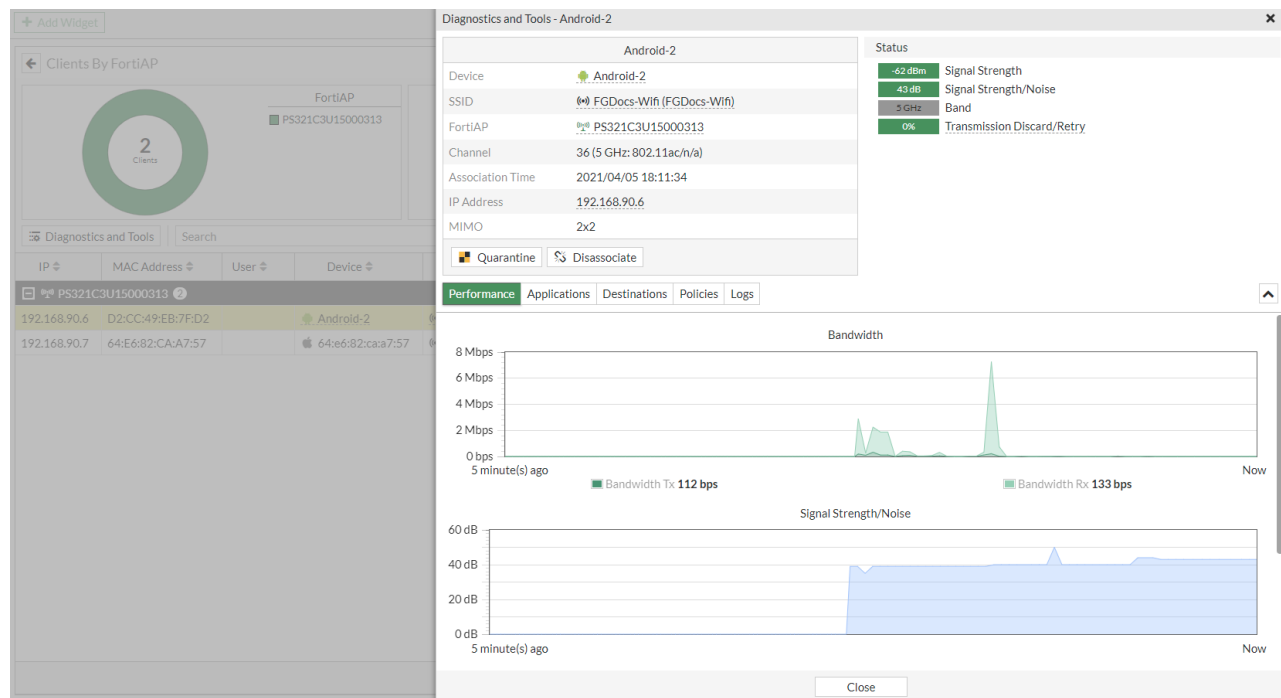

To view the *Clients by FortiAP* monitor:

1. Go to *Dashboard > WiFi*.
2. Hover over the *Clients by FortiAP* widget, and click *Expand to Full Screen*. The *Clients by FortiAP* monitor opens.
3. (Optional) Click *Save as Monitor* to save the widget as monitor.

To view the summary page for a wireless client:

1. Right-click a client in the table and select *Diagnostics and Tools*. The *Diagnostics and Tools - <device>* page is displayed.

2. (Optional) Click *Quarantine* to quarantine the client,
3. (Optional) Click *Disassociate* to disassociate the client.

Health status

The *Status* section displays the overall health for the wireless connection. The overall health of the connection is:

- Good if the value range for all three conditions are *Good*
- Fair or poor if one of the three conditions is *Fair* or *Poor* respectively.

Condition	Value Range
Signal Strength	<ul style="list-style-type: none"> • <i>Good</i> > -56dBm • -56dBm > <i>Fair</i> > -75dBm • <i>Poor</i> < -75dBm
Signal Strength/Noise	<ul style="list-style-type: none"> • <i>Good</i> > 39dBm • 20dBm < <i>Fair</i> < 39dBm • <i>Poor</i> < 20dBm
Band	<ul style="list-style-type: none"> • <i>Good</i> = 5G band • <i>Fair</i> = 2.4G band

The summary page also has the following FortiView tabs:

Monitors

FortiGate supports both FortiView and Non-FortiView monitors. FortiView monitors are driven by traffic information captured from logs and real-time data. Non-FortiView monitors capture information from various real-time state tables on the FortiGate.

Non-FortiView monitors

Non-FortiView monitors capture information on various state tables, such as the routes in the routing table, devices in the device inventory, DHCP leases in the DHCP lease table, connected VPNs, clients logged into the wireless network, and much more. These monitors are useful when troubleshooting the current state of the FortiGate, and to identify whether certain objects are in the state table or not. For more information, see [Dashboards on page 109](#).

FortiView monitors

FortiView is the FortiOS log view tool and comprehensive monitoring system for your network. FortiView integrates real-time and historical data into a single view on your FortiGate. It can log and monitor network threats, keep track of administration activities, and more.

Use FortiView monitors to investigate traffic activity such as user uploads and downloads, or videos watched on YouTube. You can view the traffic on the whole network by user group or by individual. FortiView displays the information in both text and visual format, giving you an overall picture of your network traffic activity so that you can quickly decide on actionable items.

FortiView is integrated with many UTM functions. For example, you can quarantine an IP address directly in FortiView or create custom devices and addresses from a FortiView entry.

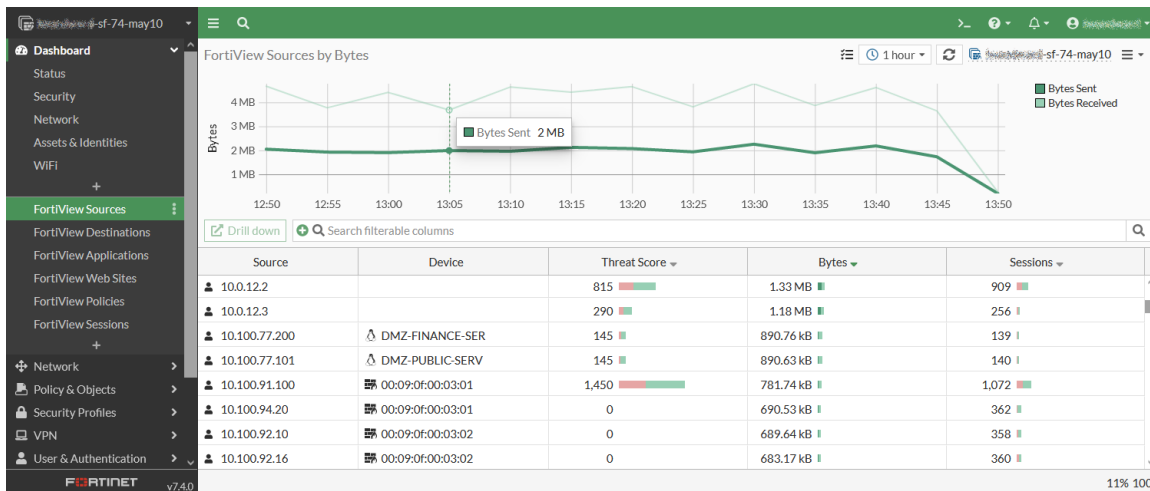

The logging range and depth will depend on the FortiGate model.

The *Optimal* template contains a set of popular default dashboards and FortiView monitors. The *Comprehensive* template contains a set of default dashboards as well as all of the FortiView monitors. See [Dashboards on page 109](#).

Template	Monitors
Optimal	<ul style="list-style-type: none"> • FortiView Sources • FortiView Destinations • FortiView Applications • FortiView Web Sites • FortiView Policies • FortiView Sessions
Comprehensive	<ul style="list-style-type: none"> • FortiView Sources • FortiView Destinations • FortiView Applications • FortiView Web Sites • FortiView Threats • FortiView Compromised Hosts • FortiView Policies • FortiView Sessions • Device Inventory Monitor • Routing Monitor • DHCP Monitor • SD-WAN Monitor • FortiGuard Quota Monitor • IPsec Monitor • SSL-VPN Monitor • Firewall User Monitor • Quarantine Monitor • FortiClient Monitor • FortiAP Clients Monitor • Rogue APs Monitor

FortiView monitors

FortiView monitors are available in the tree menu under *Dashboards*. The menu contains several default monitors for the top categories. Additional FortiView monitors are available as widgets that can be added to the dashboards. You can also add FortiView monitors directly to the tree menu with the Add (+) button.

Core FortiView monitors

The following default monitors are available in the tree menu:

Dashboard	Usage
FortiView Sources	Displays Top Sources by traffic volume and drilldown by Source.
FortiView Destinations	Displays Top Destinations by traffic volume and drilldown by Destination.
FortiView Applications	Displays Top Applications by traffic volume and drilldown by Application.
FortiView Web Sites	Displays Top Websites by session count and drilldown by Domain.
FortiView Policies	Displays Top Policies by traffic volume and drilldown by Policy number
FortiView Sessions	Displays Top Sessions by traffic source and can be used to end sessions.

Usage is based on default settings. The pages may be customized further and sorted by other fields.

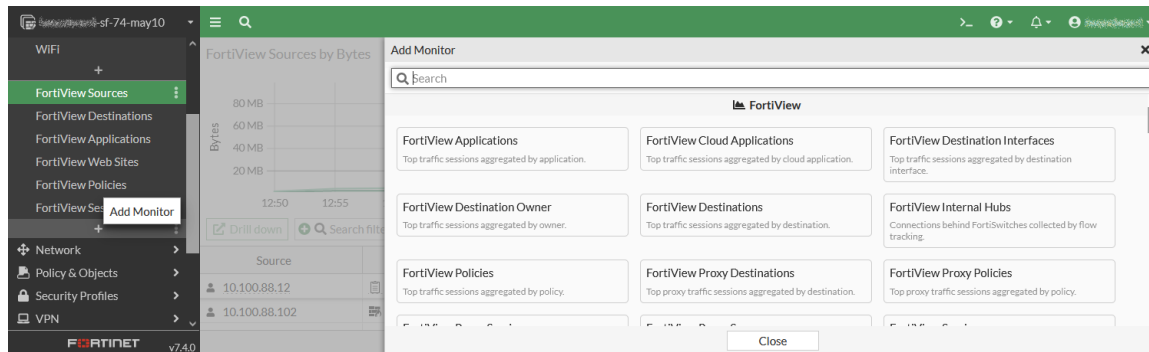

You can quarantine a host and ban an IP from all of the core FortiView monitors.

Adding FortiView monitors

Non-core FortiView monitors are available in the *Add monitor* pane. You can add a FortiView widget to a dashboard or the tree menu as a monitor.

To add a monitor to the tree menu:

1. In the tree menu, under the monitors section, click *Add Monitor (+)*.

2. Click *Add* next to a monitor. You can use the *Search* field to search for a specific monitor.
3. In the *FortiGate* area, select *All FortiGates* or *Specify* to select a FortiGate device in the security fabric.
4. (Optional) In the *Data Source* area, select *Specify* and select a source device.
5. From the *Time Period* dropdown, select the time period. This option is not available in all monitors.
6. From the *Sort By* dropdown, select the sorting method.
7. Click *Add Monitor*. The monitor is added to the tree menu.

Monitors by category

Usage is based on the default settings. The monitors may be customized further and sorted by other fields.

LANDMARK

Widget	Sort by	Usage
Applications	Bytes/Sessions/Bandwidth/Packets	Displays top applications and drilldown by application.
Application Bandwidth	Bytes/Bandwidth	Displays bandwidth for top applications and drilldown by application.
Cloud Applications	Bytes/Sessions/Files(Up/Down)	Displays top cloud applications and drilldown by application.
Cloud Users	Bytes/Sessions/Files(Up/Down)	Displays top cloud users and drilldown by cloud user.
Compromised Hosts	Verdict	Displays compromised hosts and drilldown by source.
Countries/Regions	Bytes/Sessions/Bandwidth/Packets	Displays top countries/regions and drilldown by countries/regions.
Destination Firewall Objects	Bytes/Sessions/Bandwidth/Packets	Displays top destination firewall objects and drilldown by destination objects.

Widget	Sort by	Usage
Destination Owners	Bytes/Sessions/Bandwidth/Packets	Displays top destination owners and drilldown by destination.
Destinations	Bytes/Sessions/Bandwidth/Packets	Displays top destinations and drilldown by destination.
Search Phrases	Count	Displays top search phrases and drilldown by search phrase.
Source Firewall Objects	Bytes/Sessions/Bandwidth/Packets	Displays top search phrases and drilldown by source object.
Sources	Bytes/Sessions/Bandwidth/Packets	Displays top sources and drilldown by source.
Threats	Threat level/Threat Score/Sessions	Displays top threats and drilldown by threat.
Traffic Shaping	Dropped Bytes/Bytes/Sessions/Bandwidth/Packets	Displays top traffic shaping and drilldown by shaper.
Web Categories	Bytes/Sessions/Bandwidth/Packets	Displays top web categories and drilldown by category.
Web Sites	Bytes/Sessions/Bandwidth/Packets	Displays top web sites and drilldown by domain.
WiFi Clients	Bytes/Sessions	Displays top WiFi clients and drilldown by source.

WAN

Widget	Sort by	Usage
Servers	Bytes/Sessions/Bandwidth/Packets	Displays top servers and drilldown by server address.
Sources	Bytes/Sessions/Bandwidth/Packets	Displays top sources and drilldown by device.
Threats	Threat Level/Threat Score/Sessions	Displays top threats and drilldown by threat.

All Segments

Widget	Sort by	Usage
Admin Logins	Configuration Changes/Logins/Failed Logins	Displays top admin logins by username.
Destination Interfaces	Bytes/Sessions/Bandwidth/Packets	Displays top destination interfaces by destination interface.
Endpoint Vulnerabilities	Severity	Displays top endpoint vulnerabilities by vulnerability name.

Widget	Sort by	Usage
Failed Authentication	Failed Attempts	Displays top failed authentications by failed authentication source.
FortiSandbox Files	Submitted	Displays top FortiSandbox files by file name.
Interface Pairs	Bytes/Sessions/Bandwidth/Packets	Displays top interface pairs by source interface.
Policies	Bytes/Sessions/Bandwidth/Packets	Displays top policies by policy.
Source Interfaces	Bytes/Sessions/Bandwidth/Packets	Displays top source interfaces by source interface.
System Events	Level/Events	Displays top system events by event name.
VPN	Connections/Bytes	Displays top VPN connections by user.
Vulnerable Endpoint Devices	Detected Vulnerabilities	Displays top vulnerable endpoint devices by device.

A maximum of 25 interfaces can be monitored at one time on a device.

Using the FortiView interface

Use the FortiView interface to customize the view and visualizations within a monitor to find the information you are looking for. The tools in the top menu bar allow you to change the time display, refresh or customize the data source, and filter the results. You can also right-click a table in the monitor to view drilldown information for an item.

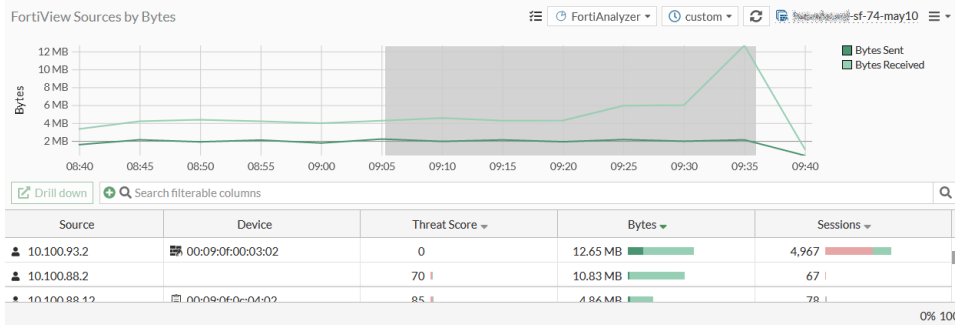

Real-time and historical charts

Use the *Time Display* dropdown to select the time period to display on the current monitor. Time display options vary depending on the monitor and can include real-time information (*now*) and historical information (*1 hour*, *24 hours*, and *7 days*).

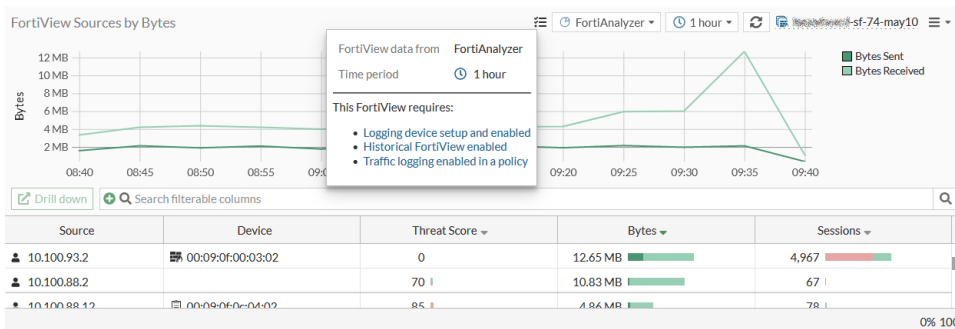

Disk logging or remote logging must be enabled to view historical information.

You can create a custom time range by selecting an area in table with your cursor.

The icon next to the time period identifies the data source (FortiGate, FortiAnalyzer, or FortiGate Cloud). Hover over its icon to see a description of the chart, as well as links to the requirements.

Data source

FortiView gathers information from a variety of data sources. If there are no log disk or remote logging configured, the data will be drawn from the FortiGate's session table, and the *Time Period* is set to *Now*.

Other data sources that can be configured are:

- FortiGate
- FortiAnalyzer
- FortiGate Cloud

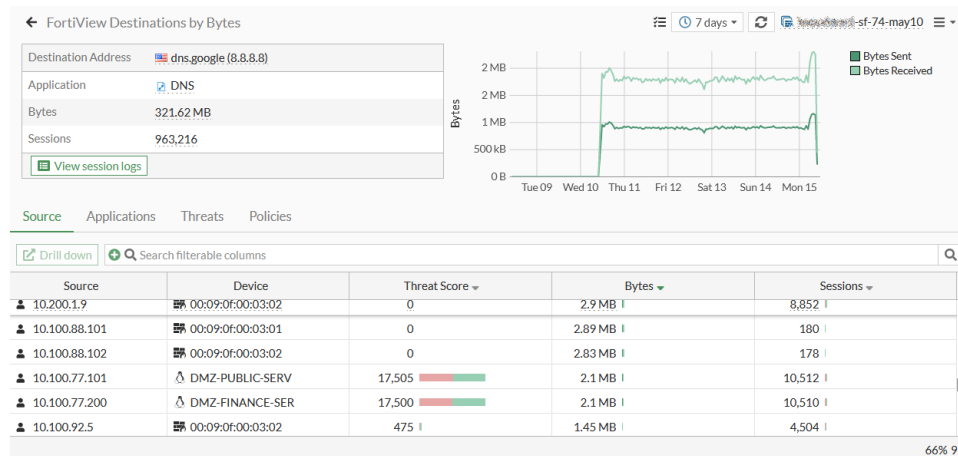

When *Data Source* is set to *Best Available Device*, FortiAnalyzer is selected when available, then FortiGate Cloud, and then FortiGate.

Drilldown information

Double-click or right-click an entry in a FortiView monitor and select *Drill Down to Details* to view additional details about the selected traffic activity. Click the *Back* icon in the toolbar to return to the previous view.

You can group drilldown information into different drilldown views. For example, you can group the drilldown information in the *FortiView Destinations* monitor by *Sources*, *Applications*, *Threats*, and *Policies*.

Select an entry, then click *View session logs* to view the session logs.

The screenshot shows the 'Sessions - dns.google (8.8.8.8) - sf-74-may10' view. It features a table of sessions with columns for Date/Time, Source, Destination, Application Name, Security Action, and Log Details. A 'Details' button is visible in the top right. The 'Log Details' panel on the right shows information for a specific session.

Date/Time	Source	Destination	Application Name	Security Action	Log Details
2023/05/15 10:29:10	10.200.1.13	8.8.8.8 (dns.google)	DNS		General Absolute Date/Time: 2023-05-15 Last Access Time: 10:29:00 Duration: 184 Session ID: 4,816,658 VDOM: root NAT Translation: snat Source Source: 10.100.92.14 Source NAT IP: 10.100.64.101 Source Port: 41,314 Source NAT Port: 41,314 Source Country/Region: Reserved Primary Source Mac: 00:09:0f:00:03:02 Device: 00:09:0f:00:03:02 Source Interface: ISFW (port3)
2023/05/15 10:29:10	10.100.93.2	8.8.8.8 (dns.google)	DNS		
2023/05/15 10:29:10	10.100.94.19	8.8.8.8 (dns.google)	DNS		
2023/05/15 10:29:10	10.200.1.13	8.8.8.8 (dns.google)	DNS		
2023/05/15 10:29:10	10.200.1.13	8.8.8.8 (dns.google)	DNS		
2023/05/15 10:29:10	10.100.94.19	8.8.8.8 (dns.google)	DNS		
2023/05/15 10:29:10	10.100.93.2	8.8.8.8 (dns.google)	DNS		
2023/05/15 10:29:10	10.100.94.19	8.8.8.8 (dns.google)	DNS		
2023/05/15 10:29:10	10.100.94.19	8.8.8.8 (dns.google)	DNS		
2023/05/15 10:29:10	10.100.93.2	8.8.8.8 (dns.google)	DNS		

At the bottom of the table, it shows '0% 43,906'.

Graph

- The graph shows the bytes sent/received in the time frame. real time does not include a chart.
- Users can customize the time frame by selecting a time period within the graph.

Summary of

- Shows information such as the user/avatar, avatar/source IP, bytes, and sessions total for the time period.
- Can quarantine host (access layer quarantine) if they are behind a FortiSwitch or FortiAP.
- Can ban IP addresses, adds the source IP address into the quarantine list.

Tabs

- Drilling down entries in any of these tabs (except sessions tab) will take you to the underlying traffic log in the sessions tab.
- *Applications* shows a list of the applications attributed to the source IP. This can include

scanned applications using Application Control in a firewall policy or unscanned applications.

```
config log gui-display
set fortiview-unscanned-apps enable
end
```

- **Destinations** shows destinations grouped by IP address/FQDN.
- **Threats** lists the threats caught by UTM profiles. This can be from antivirus, IPS, Web Filter, Application Control, etc.
- **Web Sites** contains the websites which were detected either with webfilter, or through FQDN in traffic logs.
- **Web Categories** groups entries into their categories as dictated by the Web Filter Database.
- **Policies** groups the entries into which policies they passed through or were blocked by.
- **View session logs** shows the underlying logs (historical) or sessions (real time). Drilldowns from other tabs end up showing the underlying log located in this tab.
- **Search Phrases** shows entries of search phrases on search engines captured by a Web Filter UTM profile, with deep inspection enabled in firewall policy.
- More information can be shown in a tooltip while hovering over these entries.

To view matching logs or download a log, click the **Security** tab in the **Log Details**.

The screenshot shows the FortiView Sessions tab for the date range 2023-05-15 10:49:39 to 2023-05-15 10:49:24. The table lists sessions with columns for Date/Time, Source, Destination, Application Name, and Security. A tooltip for the selected session (2023/05/15 10:49:34) shows details for the Application Control policy, including Agent (curl/7.52.1), Sensor (default), Device ID (FGVM0251403090003), Direction (outgoing), Log event original timestamp (1,684,172,972,662,394,000), Event Type (signature), Hostname (fortiguard.com), HTTP request method (GET), and Incident Serial (74.283.878).

Date/Time	Source	Destination	Application Name	Security

Enabling FortiView from devices

You can enable FortiView from SSD disk, FortiAnalyzer and FortiGate Cloud.

FortiView from disk

FortiView from disk is available on all FortiGates with an SSD disk.

Restrictions

Model	Supported view
Desktop models (100 series) with SSD	Five minutes and one hour
Medium models with SSD	Up to 24 hours

Model	Supported view
Large models (1500D and above) with SSD	Up to seven days To enable seven days view: <pre>config log setting set fortiview-weekly-data enable end</pre>

Configuration

A firewall policy needs to be in place with traffic logging enabled. For optimal operation with FortiView, internal interface roles should be clearly defined as LAN. DMZ and internet facing or external interface roles should be defined as WAN.

To configure logging to disk:

```
config log disk setting
    set status enable
end
```

To include sniffer traffic and local-deny traffic when FortiView from Disk:

```
config report setting
    set report-source forward-traffic sniffer-traffic local-deny-traffic
end
```

This feature is only supported through the CLI.

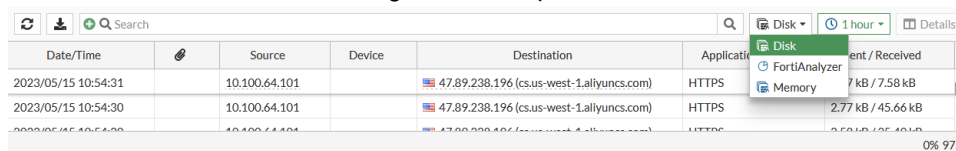

Troubleshooting

Use `execute report flush-cache` and `execute report recreate-db` to clear up any irregularities that may be caused by upgrading or cache issues.

Traffic logs

To view traffic logs from disk:

1. Go to *Log & Report*, and select either the *Forward Traffic*, *Local Traffic*, *Sniffer Traffic*, or *ZTNA Traffic* views.
2. In the toolbar, select *Disk* for the log location dropdown.

Date/Time	Source	Device	Destination	Application	Log Location	Size / Received
2023/05/15 10:54:31	10.100.64.101		47.89.238.196 (cs.us-west-1.aliyuncs.com)	HTTPS	Disk	7 kB / 7.58 kB
2023/05/15 10:54:30	10.100.64.101		47.89.238.196 (cs.us-west-1.aliyuncs.com)	HTTPS	FortiAnalyzer	2.77 kB / 45.66 kB
2023/05/15 10:54:29	10.100.64.101		47.89.238.196 (cs.us-west-1.aliyuncs.com)	HTTPS	Memory	2.50 kB / 25.40 kB

FortiView from FortiAnalyzer

Connect FortiGate to a FortiAnalyzer to increase the functionality of FortiView. Adding a FortiAnalyzer is useful when adding monitors such as the *Compromised Hosts*. FortiAnalyzer also allows you to view historical information for up to seven days.

Requirements

- A FortiGate or FortiOS
- A compatible FortiAnalyzer (see [Compatibility with FortiOS](#))

To configure logging to the FortiAnalyzer, see [Configuring FortiAnalyzer on page 2779](#)

To enable FortiView from FortiAnalyzer:

1. Go to *Dashboard > FortiView Sources*.
2. Select a time range other than *Now* from the dropdown list to view historical data.
3. In top menu, click the dropdown, and select *Settings*. The *Edit Dashboard Widget* dialog is displayed.
 - a. In the *Data Source* area, click *Specify*.
 - b. From the dropdown, select *FortiAnalyzer*, and click *OK*.

All the historical information now comes from the FortiAnalyzer.

When *Data Source* is set to *Best Available Device*, FortiAnalyzer is selected when available, then FortiGate Cloud, and then FortiGate.

FortiView from FortiGate Cloud

This function requires a FortiGate that is registered and logged into a compatible FortiGate Cloud. When using FortiGate Cloud, the *Time Period* can be set to up to 24 hours.

To configure logging to FortiGate Cloud, see [Configuring cloud logging on page 2782](#).

To enable FortiView with log source as FortiGate Cloud:

1. Go to *Dashboard > FortiView Sources*.
2. In the top menu, click the dropdown, and select *Settings*. The *Edit Dashboard Widget* window opens.
 - a. In the *Data Source* area, click *Specify*.
 - b. From the dropdown, select *FortiGate Cloud*, then click *OK*.

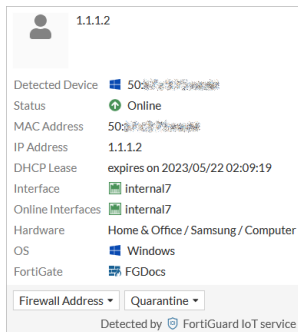

You can select FortiGate Cloud as the data source for all available FortiView pages and widgets.

FortiView sources

The *FortiView Sources* monitor displays top sources sorted by Bytes, Sessions or Threat Score. The information can be displayed in real time or historical views. You can use the monitor to create or edit a firewall device address or IP address definitions, quarantine hosts, and temporarily or permanently ban IPs.

To add a firewall device or IP address:

1. In the table, hover over the source or device MAC address. An information window opens.

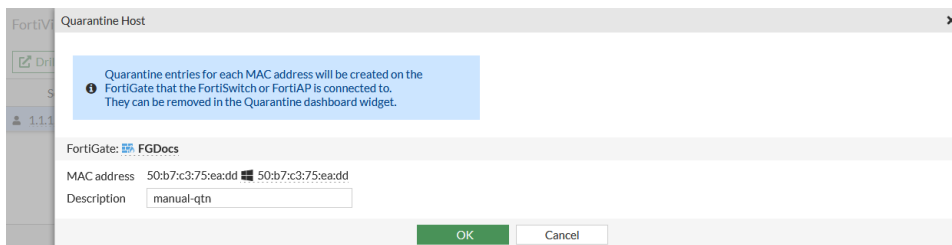

2. Click *Firewall Address > Create Firewall Device Address* or *Firewall Address > Create Firewall IP Address*. The *New Address* pane opens.
3. Configure the address settings as needed, then click *OK*.

Use the *Name* field to assign a descriptive name to a device so it is easier to find it in the *Device* column. After you finish configuring the device, refresh the page to see the new name in the monitor.

To quarantine a host:

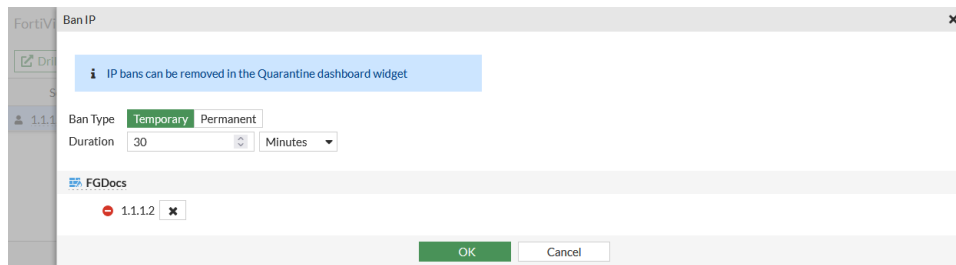

1. In the table, hover over the source or device MAC address. An information window opens.
2. Click *Quarantine > Quarantine Host*. The *Quarantine Host* dialog is displayed.
3. Configure the quarantine settings, then click *OK*.

To ban an IP address:

1. In the table, hover over the source or device MAC address. An information window opens.
2. Click *Quarantine > Ban IP*. The *Ban IP* dialog is displayed.

3. Configure the ban IP settings, then click **OK**.

FortiView Sessions

The *FortiView Sessions* monitor displays *Top Sessions* by traffic source and can be used to end sessions.

To view the *FortiView Sessions* dashboard, go to *Dashboard > FortiView Sessions*.

14% 1,000+

The session table displayed on the *FortiView Sessions* monitor is useful when verifying open connections. For example, if you have a web browser open to browse the Fortinet website, you would expect a session entry from your computer on port 80 to the IP address for the Fortinet website. You can also use a session table to investigate why there are too many sessions for FortiOS to process.

You can filter the sessions displayed in the session table by setting up the available filtering options.

To filter sessions in the session table:

1. Click on the *Add Filter* button at the top of the session table.
2. Select the required filtering option. The session table updates to the filter selection.

You can be very specific with how you use filters and target sessions based on different filter combinations. For example, you may want to view all sessions from a device with a particular IP by adding the *Source IP* filter. Similarly, you may need to target all the sessions having a particular *Destination IP* and *Destination Port*, and so on.

You may also view the session data in the CLI.

To view session data using the CLI:

```
# diagnose sys session list
```

The session table output in the CLI is very large. You can use the supported filters in the CLI to show only the data you need.

To view session data with filters using the CLI:

```
# diagnose sys session filter <option>
```

See to learn more about using the supported filters in the CLI.

You may also decide to end a particular session or all sessions for administrative purposes.

To end sessions from the GUI:

- Select the session you want to end. To select multiple sessions, hold the *Ctrl* or *Shift* key on your keyboard while clicking the sessions.

- Click on *End Session(s)* to end the selected sessions, or *End All Sessions* to end all active sessions.
- Click *OK* in the confirmation dialog.

FortiView Top Source and Top Destination Firewall Objects monitors

The *FortiView Source Firewall Objects* and *FortiView Destination Firewall Objects* monitors leverage UUID to resolve firewall object address names for improved usability.

Requirements

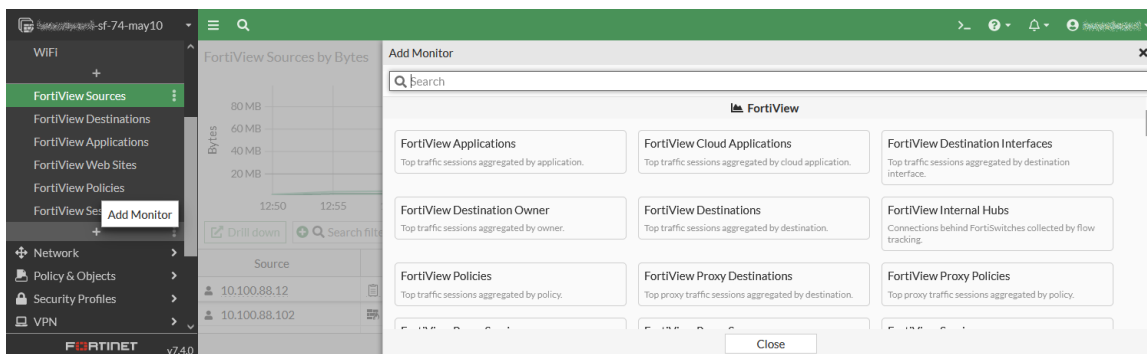

To have a historical *Firewall Objects*-based view, address objects' UUIDs need to be logged.

To enable address object UUID logging in the CLI:

```
config system global
  set log-uuid-address enable
end
```

To add a firewall object monitor in the GUI:

- Click *Add Monitor*. The *Add Monitor* window opens.

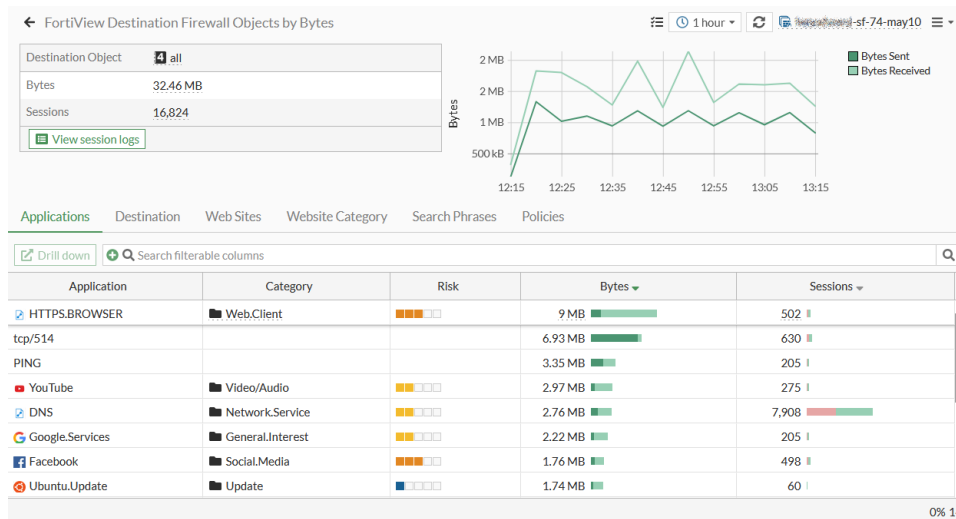

- In the *Search* field, type *Destination Firewall Objects* and click the *Add* button next to the dashboard name.
- In the *FortiGate* area, select the FortiGate(s) from the dropdown.
- In the *Data Source* area, select *Best Available Device* or *Specify*. For information, see [Using the FortiView interface on page 138](#).
- From the *Time Period* dropdown, select the time period. Select *now* for real-time information, or (*1 hour*, *24 hours*, and *7 days*) for historical information.

- From the *Sort By* dropdown, select *Bytes*, *Sessions*, *Bandwidth*, or *Packets*.
- Click *OK*. The monitor is added to the tree menu.

To drill down Firewall Objects:

- Open the *FortiView Source Firewall Objects* or *FortiView Destination Firewall Objects* monitor.
- Select any source or destination object and click *Drill down*.
- Click the tabs to sort the sessions.

- Select an entry, then click *View session logs* to view the session logs.

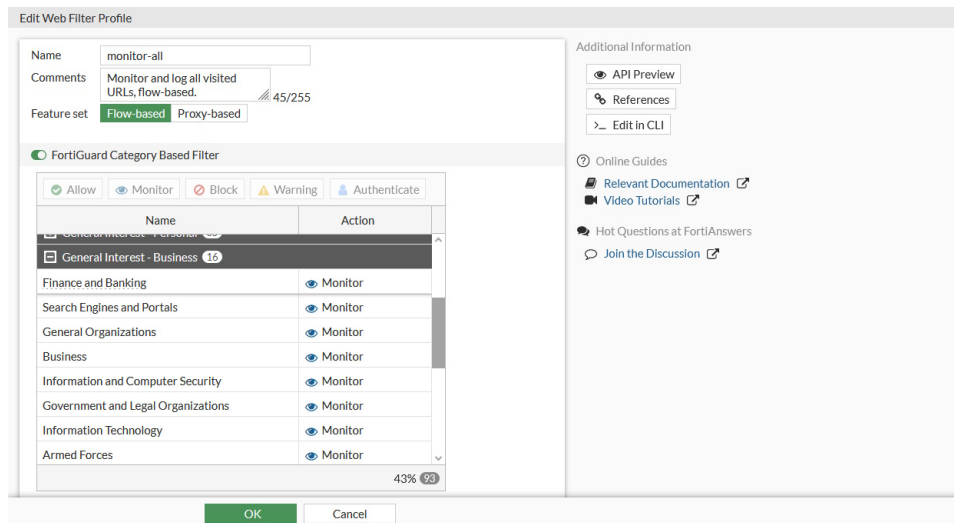

Viewing top websites and sources by category

You can use FortiGuard web categories to populate the category fields in various FortiView monitors such as *FortiView Web Categories*, *FortiView Websites* or *FortiView Sources*. To view the categories in a monitor, the web filter profile must be configured to at least monitor for a FortiGuard category based on a web filter and applied to a firewall policy for outbound traffic.

To verify the web filter profile is monitor-only:

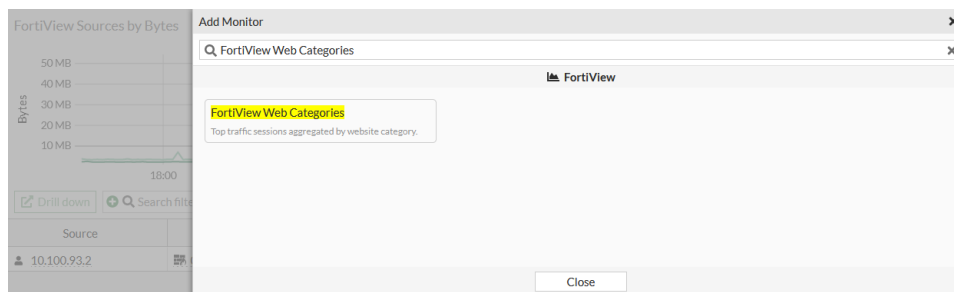

- Go to *Security Profiles > Web Filter*.
- Double-click a web filter that is applied to an outbound traffic firewall policy. The *Edit Web Filter Profile* window opens.
- Ensure *FortiGuard Category Based Filter* is enabled.

In this example, the *General Interest - Business* categories are monitor-only.

To create a Web categories monitor:

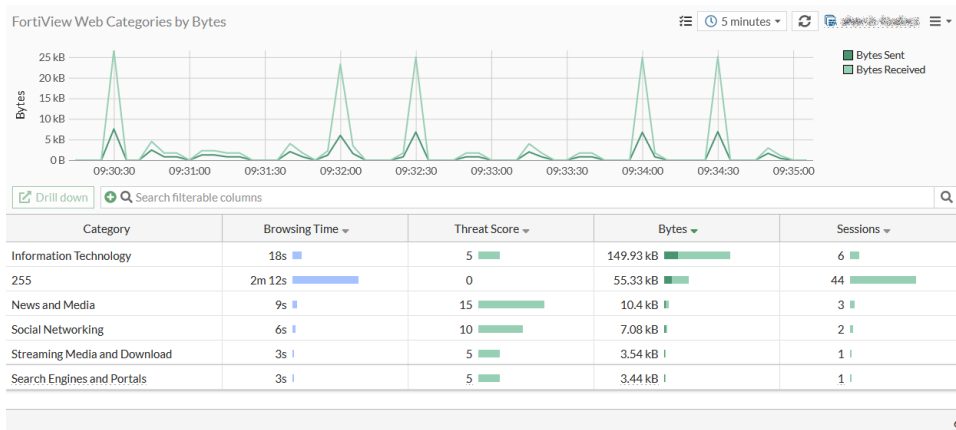

1. Click *Add Monitor*. The *Add Monitor* window opens.
2. In the *Search* field, type *FortiView Web Categories* and click the *Add* button next to the monitor name.

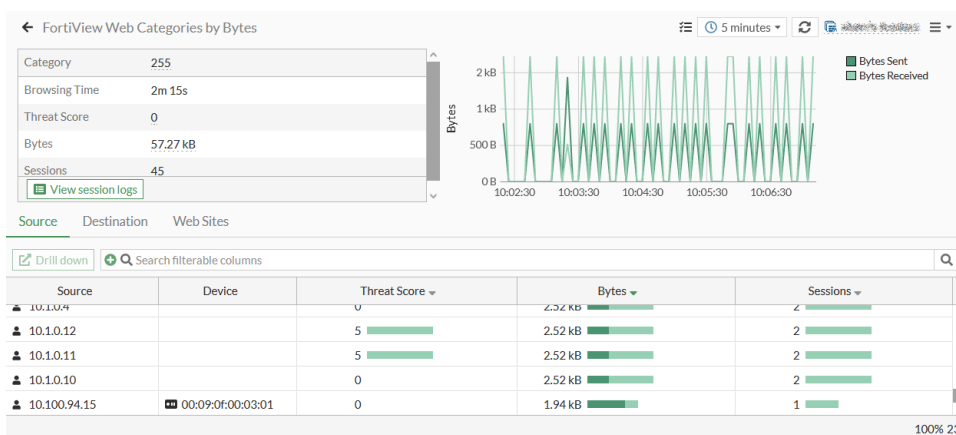

3. In the *FortiGate* area, select the FortiGate(s) from the dropdown.
4. In the *Data Source* area, click *Best Available Device* or *Specify* to select a device in the security fabric.
5. From the *Time Period* dropdown, select a time period greater than *Now*.
6. From the *Sort By* dropdown, select *Browsing Time*, *Threat Score*, *Bytes*, or *Sessions*.
7. Click *OK*. The widget is added to the tree menu.

Viewing the web filter category

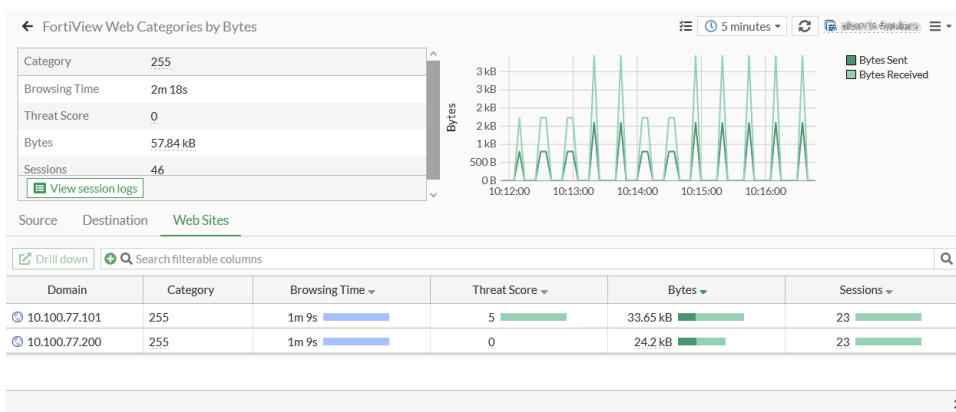

The web filter category name appears in the *Category* column of the dashboard.

Drill down an entry in the table.

Click the **Web Sites** tab. The category name appears in the **Category** column.

Click **View session logs** to view a list of the session logs. The category name appears in the **Category** column.

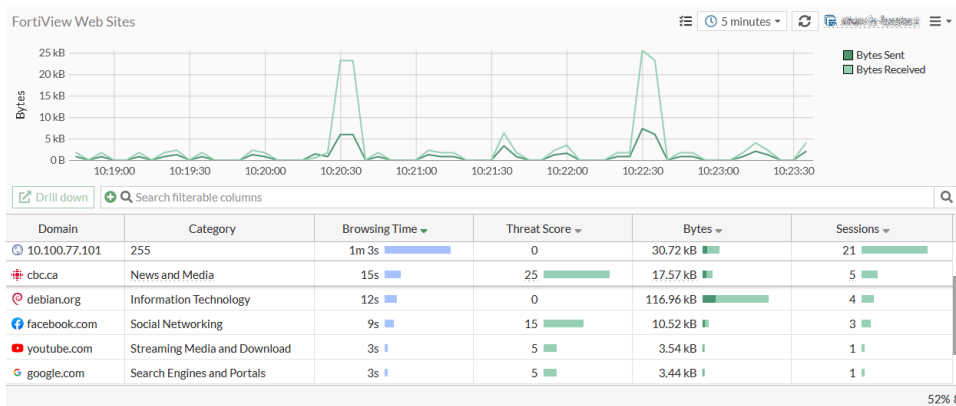

Sessions - 10.100.77.200

0% 106

The category name also appears in the *Category* column in the *FortiView Websites* monitor and when drilling down in the *FortiView Sources* monitor.

Cloud application view

To see different cloud application views, set up the following:

- A FortiGate with a firewall policy that uses the *Application Control* security profile.
- A FortiGate with log data from the local disk or FortiAnalyzer.
- Optional but highly recommended: *SSL Inspection* set to *deep-inspection* in the related firewall policies.

Viewing cloud applications

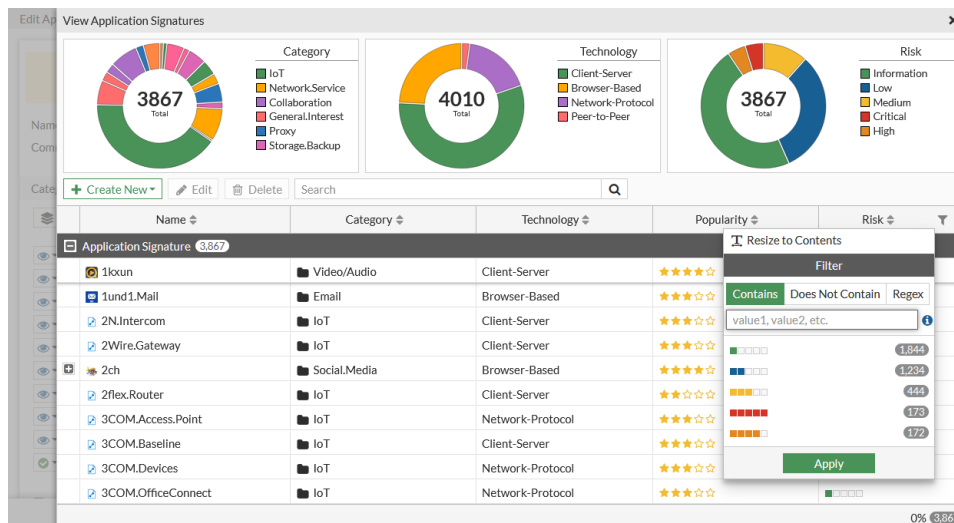

All cloud applications require *SSL Inspection* set to *deep-inspection* on the firewall policy. For example, *Facebook_File.Download* can monitor Facebook download behavior which requires *SSL deep-inspection* to parse the deep information in the network packets.

To view cloud applications:

1. Go to *Security Profiles > Application Control*.
2. Select an Application Control profile that is used by the firewall policy and click *Edit*.
3. On the *Edit Application Sensor* page, click *View Application Signatures*.

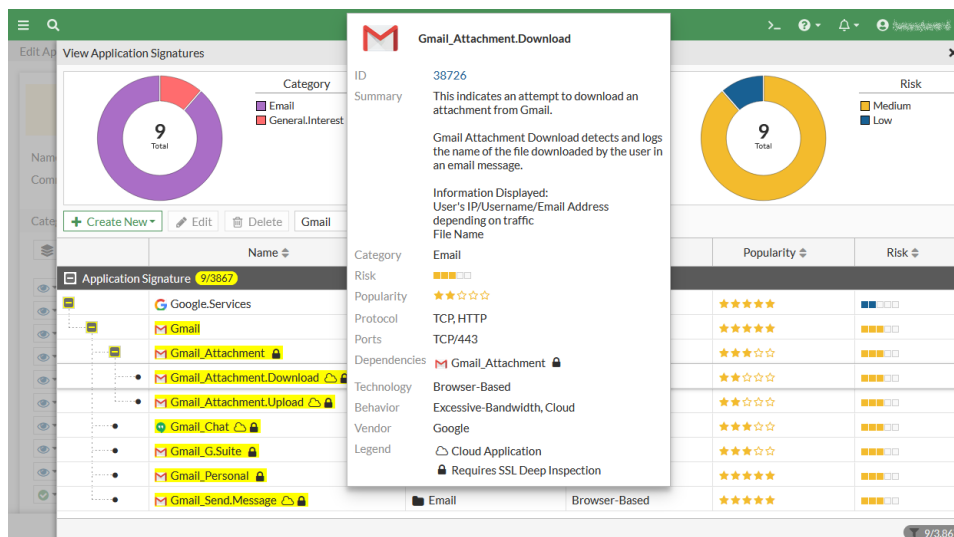

4. Hover over a column heading or the *Application Signature* bar. On the right, click the filter icon to filter the applications.

Cloud applications have a cloud icon next to them. The lock icon indicates that the application requires SSL deep inspection.

5. Hover over an item to see its details.

This example shows *Gmail_Attachment.Download*, a cloud application signature based sensor which requires SSL deep inspection. If any local network user behind the firewall logs into Gmail and downloads a Gmail attachment, that activity is logged.

Applications with cloud behavior

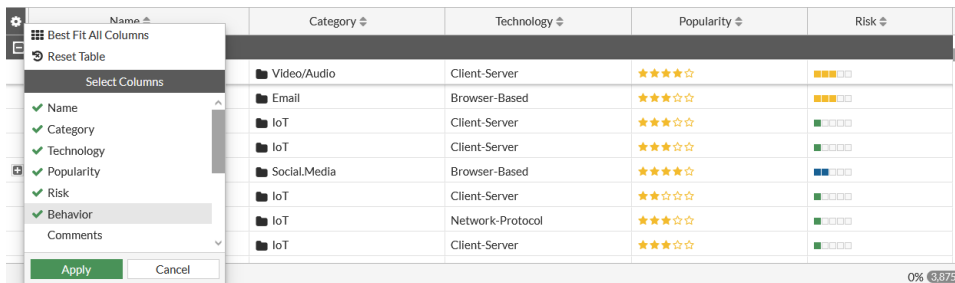

Applications with cloud behavior is a superset of cloud applications.

Some applications do not require SSL deep inspection, such as Facebook, Gmail, and YouTube. This means that if any traffic trigger application sensors for these applications, there is a FortiView cloud application view for that traffic.

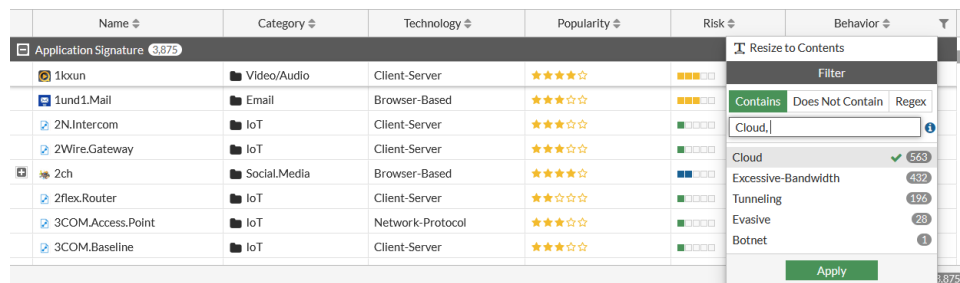

Other applications require SSL deep inspection, such as Gmail attachment, Facebook_Workplace, and so on.

To view applications with cloud behavior:

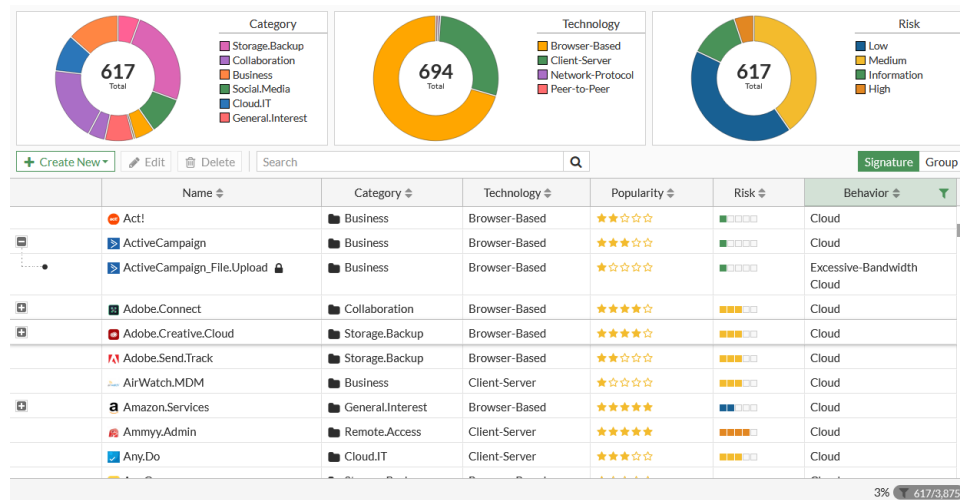

1. In the *Application Signature* page, ensure the *Behavior* column is displayed. If necessary, add the *Behavior* column.
 - a. Hover over the left side of the table column headings to display the *Configure Table* icon.
 - b. Click *Configure Table* and select *Behavior*.
 - c. Click *Apply*.

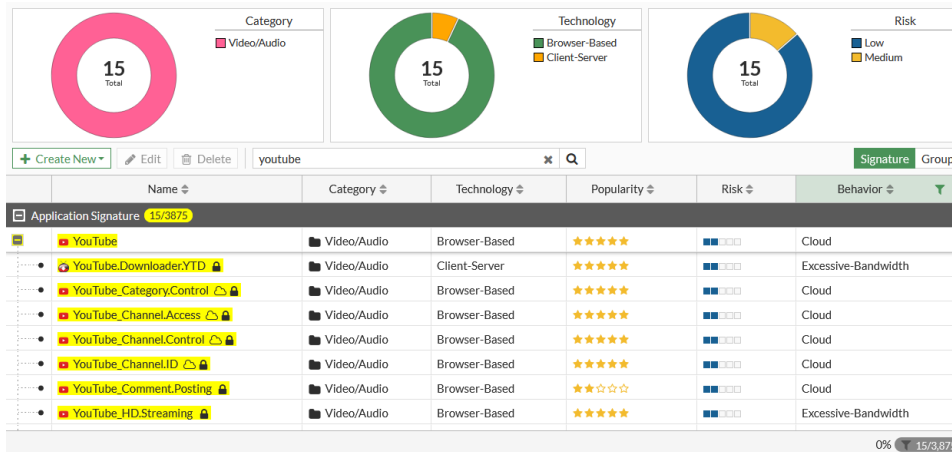

2. Click the filter icon in the *Behavior* column and select *Cloud* to filter by Cloud. Then click *Apply*.

3. The *Application Signature* page displays all applications with cloud behavior.

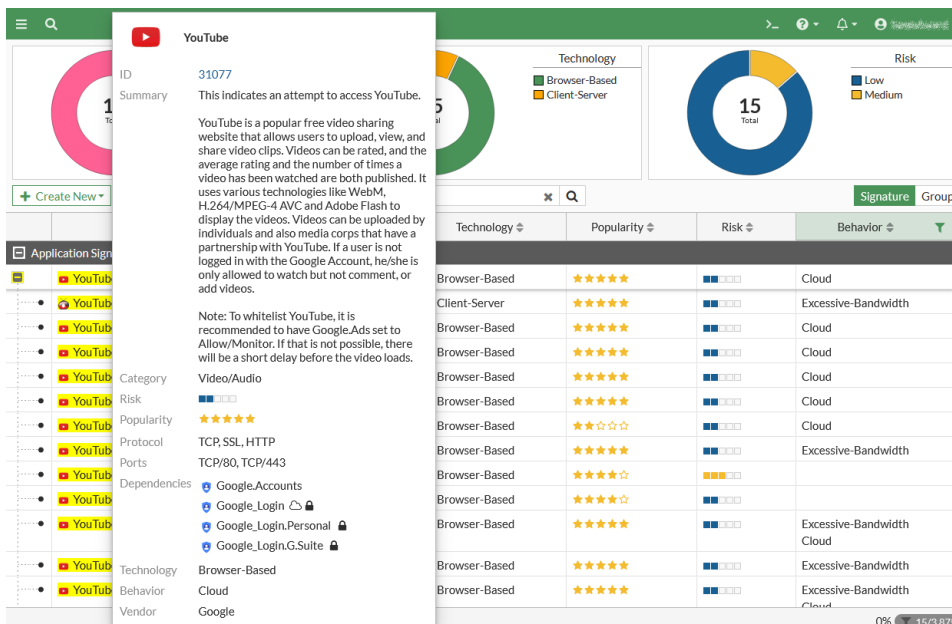

4. Use the *Search* box to search for applications. For example, you can search for *youtube*.

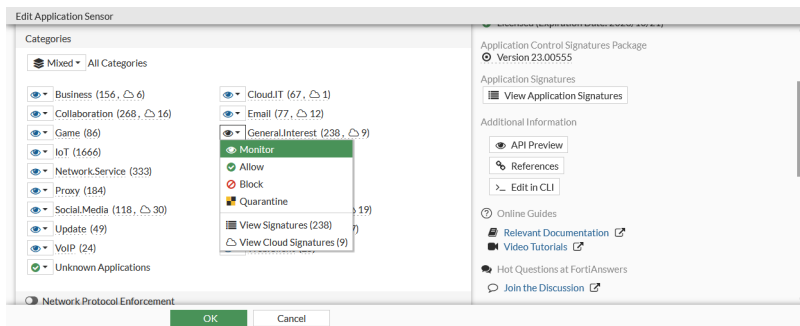

5. Hover over an item to see its details.

This example shows an application sensor with no lock icon which means that this application sensor does not require SSL deep inspection. If any local network user behind the firewall tries to navigate to the YouTube website, that activity is logged.

Configuring the Cloud Applications monitor

Go to *Security Profiles > Application Control* and edit a profile. On the *Edit Application Sensor* page in the *Categories* section, the eye icon next to a category means that category is monitored and logged.

To add the Cloud Applications monitor in the GUI:

1. Click **Add Monitor**. The *Add monitor* window opens.
2. In the **Search** field, enter *FortiView Cloud Applications* and click the **Add** button next to the monitor.

3. In the **FortiGate** area, select the FortiGate(s) from the dropdown.
4. In the **Data Source** area, click *Best Available Device* or *Specify* to select a device in the security fabric.
5. From the **Time Period** dropdown, select a time period greater than *Now*.
6. From the **Sort By** dropdown, select *Bytes*, *Sessions*, *Files (Up/Down)*, or *Videos Played*.
7. Click **OK**. The monitor is added to the tree menu.
8. Open the monitor. If SSL deep inspection is enabled in the related firewall policy, then the monitor shows the additional details that are logged, such as *Files (Up/Down)* and *Videos Played*.
 - For YouTube, the *Videos Played* column is triggered by the *YouTube_Video.Play* cloud application sensor. This shows the number of local network users who logged into YouTube and played YouTube videos.
 - For Dropbox, the *Files (Up/Down)* column is triggered by *Dropbox_File.Download* and *Dropbox_File.Upload* cloud application sensors. This shows the number of local network users who logged into Dropbox and uploaded or downloaded files.

Application	Category	Risk	Bytes	Sessions	Files (Up/Down)	Videos Played
YouTube	Video/Audio	Low	137.53 MB	120	0	34
Dropbox	Storage Backup	Low	7.34 MB	29	1	0
Google Hangouts	Collaboration	Low	35.21 KB	3	0	0
Facebook	Social/Media	Low	33.03 KB	6	0	0
Skype	Collaboration	Low	32.92 KB	1	0	0

Using the Cloud Applications monitor

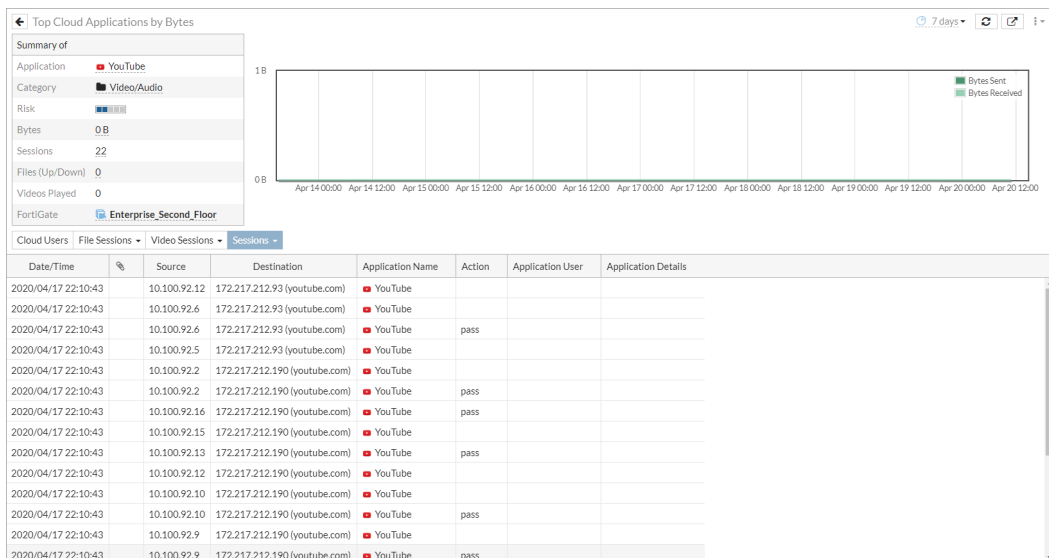

To see additional information in the Cloud Applications monitor:

1. In the tree menu, click the *FortiView Cloud Applications* monitor to open it.

2. For details about a specific entry, double-click the entry or right-click the entry and select *Drill Down to Details*.
3. To see all the sessions for an application, click *Sessions*.

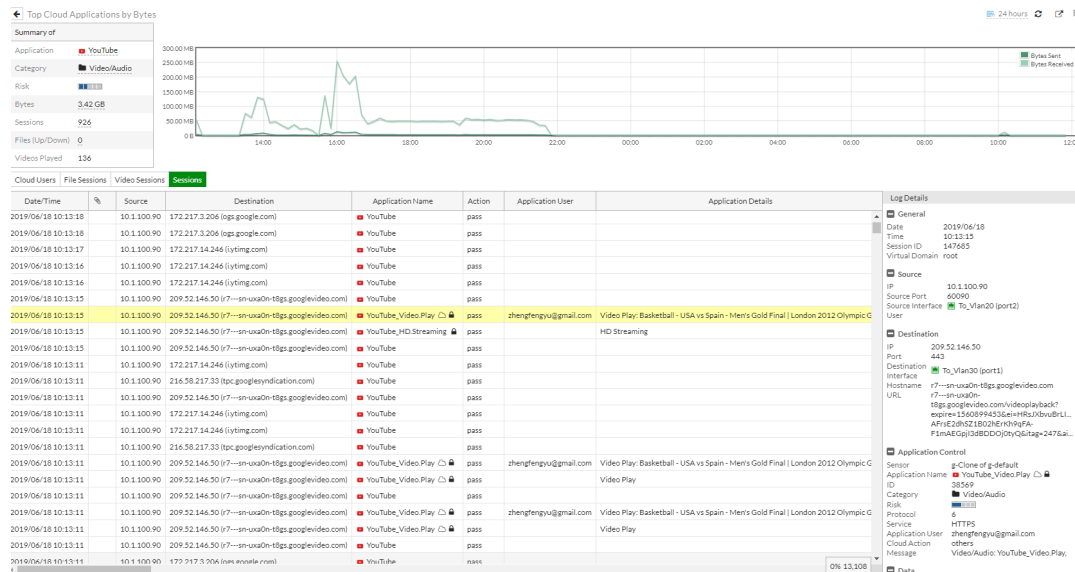

In this example, the *Application Name* column shows all applications related to YouTube.

4. To view log details, double-click a session to display the *Log Details* pane.

Sessions monitored by SSL deep inspection (in this example, Youtube_Video.Play) captured deep information such as *Application User*, *Application Details*, and so on. The *Log Details* pane also shows additional deep information such as application *ID*, *Message*, and so on.

Sessions not monitored by SSL deep inspection (YouTube) did not capture the deep information.

- 5.** To display a specific time period, select and drag in the timeline graph to display only the data for that time period.

Top application: YouTube example

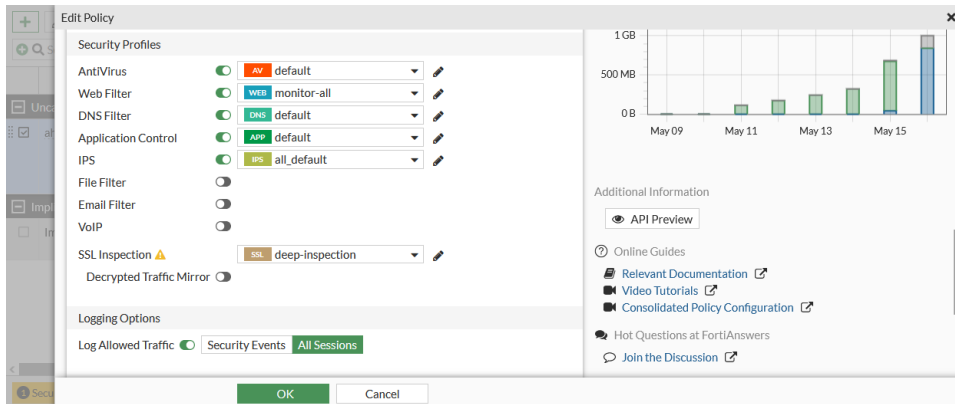

Monitoring network traffic with SSL deep inspection

This example describes how to monitor network traffic for YouTube using *FortiView Applications* view with SSL deep inspection.

To monitor network traffic with SSL deep inspection:

1. Create a firewall policy with the following settings:
 - *Application Control* is enabled.
 - *SSL Inspection* is set to *deep-inspection*.

- *Log Allowed Traffic* is set to *All Sessions*.

2. Go to *Security Profiles > Application Control*.
3. Select a related Application Control profile used by the firewall policy and click *Edit*.
4. Because YouTube cloud applications are categorized into *Video/Audio*, ensure the *Video/Audio* category is monitored. Monitored categories are indicated by an eye icon.
5. Click *View Application Signatures* and hover over YouTube cloud applications to view detailed information about YouTube application sensors.
6. Expand *YouTube* to view the Application Signatures associated with the application.

Application Signature	Description	Application ID
<i>YouTube_Video.Access</i>	An attempt to access a video on YouTube.	16420
<i>YouTube_Channel.ID</i>	An attempt to access a video on a specific channel on YouTube.	44956
<i>YouTube_Comment.Posting</i>	An attempt to post comments on YouTube.	31076
<i>YouTube_HD.Streaming</i>	An attempt to watch HD videos on YouTube.	33104
<i>YouTube_Messenger</i>	An attempt to access messenger on YouTube.	47858
<i>YouTube_Video.Play</i>	An attempt to download and play a video from YouTube.	38569
<i>YouTube_Video.Upload</i>	An attempt to upload a video to YouTube.	22564
<i>YouTube</i>	An attempt to access YouTube. This application sensor does not depend on SSL deep inspection so it does not have a cloud or lock icon.	31077
<i>YouTube_Channel.Access</i>	An attempt to access a video on a specific channel on YouTube.	41598

To view the application signature description, click the ID link in the information window.

7. On the test PC, log into YouTube and play some videos.

- On the FortiGate, go to **Log & Report > Security Events**, select **Application Control**, and look for log entries for browsing and playing YouTube videos.

In this example, note the **Application User** and **Application Details**. Also note that the **Application Control ID** is 38569 showing that this entry was triggered by the application sensor **YouTube_Video.Play**.

- Go to **Dashboard > FortiView Applications**.
- In the **FortiView Applications** monitor, double-click **YouTube** to view the drilldown information.
- Click **View session logs** to see all the entries for the videos played. Check the sessions for **YouTube_Video.Play** with the ID 38569.

Monitoring network traffic without SSL deep inspection

This example describes how to monitor network traffic for YouTube using FortiView cloud application view without SSL deep inspection.

To monitor network traffic without SSL deep inspection:

- Create a firewall policy with the following settings.
 - Application Control** is enabled.
 - SSL Inspection** is set to **certificate-inspection**.
 - Log Allowed Traffic** is set to **All Sessions**.

- On the test PC, log into YouTube and play some videos.

- On the FortiGate, go to **Log & Report > Security Events** and look for log entries for browsing and playing YouTube videos in the **Application Control** card.

In this example, the log shows only applications with the name YouTube. The log cannot show YouTube application sensors which rely on SSL deep inspection.

- Go to **Dashboard > FortiView Applications**.

The **FortiView Application by Bytes** monitor shows the YouTube cloud application without the video played information that requires SSL deep inspection.

- Double-click **YouTube** and click **View session logs**.

These sessions were triggered by the application sensor **YouTube** with the ID **31077**. This is the application sensor with cloud behavior which does not rely on SSL deep inspection.

Sessions - Application by Bytes

Interfaces

Physical and virtual interfaces allow traffic to flow between internal networks, and between the internet and internal networks. FortiOS has options for configuring interfaces and groups of sub-networks that can scale as your organization grows. The following table lists commonly used interface types.

Interface type	Description
Physical	A physical interface can be connected to with either Ethernet or optical cables. Depending on the FortiGate model, there is a varying number of Ethernet or optical physical interfaces. Some FortiGates have a grouping of interfaces labeled as <i>lan</i> that have a built-in switch functionality. See Physical interface on page 188 for more information.

Interface type	Description
VLAN	<p>A virtual local area network (VLAN) logically divides a local area network (LAN) into distinct broadcast domains using IEEE 802.1Q VLAN tags. A VLAN interface supports VLAN tagging and is associated with a physical interface that can be connected to a device, such as a switch or a router that supports these tags. VLANs can be used on a FortiGate in NAT or transparent mode, and the FortiGate functions differently depending on the operation mode.</p> <p>See VLAN on page 189 for more information.</p>
Aggregate	<p>An aggregate interface uses a link aggregation method to combine multiple physical interfaces to increase throughput and to provide redundancy. FortiOS supports a link aggregation (LAG) interface using the Link Aggregation Control Protocol (LACP) based on IEEE 802.3ad.</p> <p>See Aggregation and redundancy on page 205 for more information.</p>
Redundant	<p>A redundant interface combines multiple physical interfaces where traffic only uses one of the interfaces at a time. Its primary purpose is to provide redundancy. This interface is typically used with a fully-meshed HA configuration.</p> <p>See Aggregation and redundancy on page 205 for more information.</p>
Loopback	<p>A loopback interface is a logical interface that is always up because it has no physical link dependency, and the attached subnet is always present in the routing table. It can be accessed through several physical or VLAN interfaces.</p> <p>See Loopback interface on page 213 for more information.</p>
Software switch	<p>A software switch is a virtual switch interface implemented in firmware that allows member interfaces to be added to it. Devices connected to member interfaces communicate on the same subnet, and packets are processed by the FortiGate's CPU. A software switch supports adding a wireless SSID as a member interface.</p> <p>See Software switch on page 214 for more information.</p>
Hardware switch	<p>A hardware switch is a virtual switch interface implemented at the hardware level that allows member interfaces to be added to it. Devices connected to member interfaces communicate on the same subnet. A hardware switch relies on specific hardware to optimize processing and supports the Spanning Tree Protocol (STP).</p> <p>See Hardware switch on page 216 for more information.</p>
Zone	<p>A zone is a logical group containing one or more physical or virtual interfaces. Grouping interfaces in zones can simplify firewall policy configurations.</p> <p>See Zone on page 220 for more information.</p>
Virtual wire pair	<p>A virtual wire pair (VWP) is an interface that acts like a virtual wire consisting of two interfaces, with an interface at each of the wire. No IP addressing is configured on a VWP, and communication is restricted between the two interfaces using firewall policies.</p> <p>See Virtual wire pair on page 222 for more information.</p>
FortiExtender WAN extension	<p>A FortiExtender WAN extension is a managed interface that allows a connected FortiExtender to provide WAN connectivity to the FortiGate.</p> <p>See FortiExtender on page 540 for more information.</p>

Interface type	Description
FortiExtender LAN extension	A FortiExtender LAN extension is a managed interface that allows a connected FortiExtender to provide LAN connectivity to the FortiGate. See FortiExtender on page 540 for more information.
Enhanced MAC VLAN	An enhanced media access control (MAC) VLAN, or EMAC VLAN, interface allows a physical interface to be virtually subdivided into multiple virtual interfaces with different MAC addresses. In FortiOS, the EMAC VLAN functionality acts like a bridge. See Enhanced MAC VLAN on page 229 for more information.
VXLAN	A Virtual Extensible LAN (VXLAN) interface encapsulates layer 2 Ethernet frames within layer 3 IP packets and is used for cloud and data center networks. See VXLAN on page 232 for more information.
Tunnel	A tunnel virtual interface is used for IPsec interface-based or GRE tunnels and are created when configuring IPsec VPN and GRE tunnels, respectively. The tunnel interface can be configured with IP addresses on both sides of the tunnel since this is a requirement when using a tunnel interface with a dynamic routing protocol. See OSPF with IPsec VPN for network redundancy on page 1894 , GRE over IPsec on page 1811 , and Cisco GRE-over-IPsec VPN on page 1841 for more information.
WiFi SSID	A WiFi SSID interface is used to control wireless network user access to a wireless local radio on a FortiWiFi or to a wireless access point using a FortiAP. The SSID is created using the <i>WiFi & Switch Controller > SSIDs</i> page, and it appears in the <i>Network > Interfaces</i> page once it is created. See Defining a wireless network interface (SSID) in the FortiWiFi and FortiAP Configuration Guide for more information.
VDOM link	A VDOM link allows VDOMs to communicate internally without using additional physical interfaces. See Inter-VDOM routing for more information.

Interface settings

Administrators can configure both physical and virtual FortiGate interfaces in *Network > Interfaces*. There are different options for configuring interfaces when FortiGate is in NAT mode or transparent mode.

The available options will vary depending on feature visibility, licensing, device model, and other factors. The following list is not comprehensive.

To configure an interface in the GUI:

1. Go to *Network > Interfaces*.
2. Click *Create New > Interface*.

3. Configure the interface fields:

Interface Name	Physical interface names cannot be changed.
Alias	<p>Enter an alternate name for a physical interface on the FortiGate unit. This field appears when you edit an existing physical interface. The alias does not appear in logs.</p> <p>The maximum length of the alias is 25 characters.</p>
Type	The configuration type for the interface, such as VLAN, Software Switch, 802.3ad Aggregate, and others.
Interface	<p>This field is available when <i>Type</i> is set to <i>VLAN</i>.</p> <p>Select the name of the physical interface that you want to add a VLAN interface to. Once created, the VLAN interface is listed below its physical interface in the <i>Interface</i> list.</p> <p>You cannot change the physical interface of a VLAN interface.</p>
VLAN ID	<p>This field is available when <i>Type</i> is set to <i>VLAN</i>.</p> <p>Enter the VLAN ID. The VLAN ID can be any number between 1 and 4094 and must match the VLAN ID added by the IEEE 802.1Q-compliant router or switch that is connected to the VLAN subinterface.</p> <p>The VLAN ID can be edited after the interface is added.</p>
VRF ID	Virtual Routing and Forwarding (VRF) allows multiple routing table instances to coexist on the same router. One or more interface can have a VRF, and packets are only forwarded between interfaces with the same VRF.
Virtual Domain	<p>Select the virtual domain to add the interface to.</p> <p>Only administrator accounts with the <i>super_admin</i> profile can change the <i>Virtual Domain</i>.</p>
Interface Members	<p>This section can have different formats depending on the <i>Type</i>.</p> <p>Members can be selected for some interface types:</p> <ul style="list-style-type: none"> • <i>Software Switch</i> or <i>Hardware Switch</i>: Specify the physical and wireless interfaces joined into the switch. • <i>802.3ad Aggregate</i> or <i>Redundant Interface</i>: This field includes the available and selected interface lists.
Role	<p>Set the role setting for the interface. Different settings will be shown or hidden when editing an interface depending on the role:</p> <ul style="list-style-type: none"> • <i>LAN</i>: Used to connected to a local network of endpoints. It is default role for new interfaces. • <i>WAN</i>: Used to connected to the internet. When WAN is selected, the <i>Estimated bandwidth</i> setting is available, and the following settings are not: <i>DHCP server</i>, <i>Create address object matching subnet</i>, <i>Device detection</i>, <i>Security mode</i>, <i>One-arm sniffer</i>, <i>Dedicate to extension/fortiap modes</i>, and <i>Admission Control</i>.and will show Estimated Bandwidth settings. • <i>DMZ</i>: Used to connected to the DMZ. When selected, <i>DHCP server</i> and <i>Security mode</i> are not available.

	<ul style="list-style-type: none"> • <i>Undefined</i>: The interface has no specific role. When selected, <i>Create address object matching subnet</i> is not available.
Estimated bandwidth	<p>The estimated WAN bandwidth.</p> <p>The values can be entered manually, or saved from a speed test executed on the interface. The values can be used in SD-WAN rules that use the Maximize Bandwidth or Best Quality strategy.</p>
Traffic mode	<p>This option is only available when <i>Type</i> is <i>WiFi SSD</i>.</p> <ul style="list-style-type: none"> • <i>Tunnel</i>: Tunnel to wireless controller • <i>Bridge</i>: Local bridge with FortiAP's interface • <i>Mesh</i>: Mesh downlink
Address	
Addressing mode	<p>Select the addressing mode for the interface.</p> <ul style="list-style-type: none"> • <i>Manual</i>: Add an IP address and netmask for the interface. If IPv6 configuration is enabled, you can add both an IPv4 and an IPv6 address. • <i>DHCP</i>: Get the interface IP address and other network settings from a DHCP server. • <i>Auto-managed by IPAM</i>: Assign subnets to prevent duplicate IP addresses from overlapping within the same Security Fabric. See Configure IPAM locally on the FortiGate on page 169. • <i>PPPoE</i>: Get the interface IP address and other network settings from a PPPoE server. This option is only available on the low-end FortiGate models. • <i>One-Arm Sniffer</i>: Set the interface as a sniffer port so it can be used to detect attacks. See One-arm sniffer on page 177.
IP/Netmask	<p>If <i>Addressing Mode</i> is set to <i>Manual</i>, enter an IPv4 address and subnet mask for the interface. FortiGate interfaces cannot have multiple IP addresses on the same subnet.</p>
IPv6 addressing mode	<p>Select the addressing mode for the interface:</p> <ul style="list-style-type: none"> • <i>Manual</i>: Add an IP address and netmask for the interface. • <i>DHCP</i>: Get the interface IP address and other network settings from a DHCP server. • <i>Delegated</i>: Select an <i>IPv6 upstream interface</i> that has DHCPv6 prefix delegation enabled, and enter an <i>IPv6 subnet</i> if needed. The interface will get the IPv6 prefix from the upstream DHCPv6 server that is connected to the IPv6 upstream interface, and form the IPv6 address with the subnet configured on the interface.
IPv6 Address/Prefix	<p>If <i>Addressing Mode</i> is set to <i>Manual</i> and IPv6 support is enabled, enter an IPv6 address and subnet mask for the interface. A single interface can have an IPv4 address, IPv6 address, or both.</p>
Auto configure IPv6 address	<p>Automatically configure an IPv6 address using Stateless Address Auto-configuration (SLAAC).</p> <p>This option is available when <i>IPv6 addressing mode</i> is set to <i>Manual</i>.</p>

DHCPv6 prefix delegation	<p>Enable/disable DHCPv6 prefix delegation, which can be used to delegate IPv6 prefixes from an upstream DHCPv6 server to another interface or downstream device.</p> <p>When enabled, there is an option to enable a <i>DHCPv6 prefix hint</i> that helps the DHCPv6 server provide the desired prefix.</p>
Create address object matching subnet	<p>This option is available and automatically enabled when <i>Role</i> is set to <i>LAN</i> or <i>DMZ</i>.</p> <p>This creates an address object that matches the interface subnet and dynamically updates the object when the IP/Netmask changes.</p> <p>See Interface subnet on page 1317 for more information.</p>
Secondary IP Address	Add additional IPv4 addresses to this interface.
Administrative Access	
IPv4 Administrative Access	Select the types of administrative access permitted for IPv4 connections to this interface. See Configure administrative access to interfaces on page 167 .
IPv6 Administrative Access	Select the types of administrative access permitted for IPv6 connections to this interface. See Configure administrative access to interfaces on page 167 .
DHCP Server	Enable a DHCP server for the interface. See DHCP servers and relays on page 384 .
Stateless Address Auto-configuration (SLAAC)	Enable to provide IPv6 addresses to connected devices using SLAAC.
DHCPv6 Server	<p>Select to enable a DHCPv6 server for the interface.</p> <p>When enabled, you can configure <i>DNS service</i> settings: <i>Delegated</i> (delegate the DNS received from the upstream server), <i>Same as System DNS</i>, or <i>Specify</i> (up to four servers).</p> <p>You can also enable <i>Stateful server</i> to configure the DHCPv6 server to be stateful. Manually enter the IP range, or use Delegated mode to delegate IP prefixes from an upstream DHCPv6 server connected to the upstream interface.</p>
Network	
Device Detection	Enable/disable passively gathering device identity information about the devices on the network that are connected to this interface.
Security Mode	Enable/disable captive portal authentication for this interface. After enabling captive portal authentication, you can configure the authentication portal, user and group access, custom portal messages, exempt sources and destinations/services, and redirect after captive portal.
DSL Settings	
Physical mode	Set to <i>ADSL</i> or <i>VDSL</i> .
Transfer mode	<p>Set to <i>PTM</i> or <i>ATM</i>.</p> <p>If the <i>Transfer mode</i> is set to <i>ATM</i>, the <i>Virtual channel identification</i>, <i>Virtual path identification</i>, <i>ATM protocol</i>, and <i>MUX type</i> can be configured.</p>

Traffic Shaping

Outbound shaping profile Enable/disable traffic shaping on the interface. This allows you to enforce bandwidth limits on individual interfaces. See [Interface-based traffic shaping profile on page 1385](#) for more information.

Miscellaneous

Comments Enter a description of the interface of up to 255 characters.

Status Enable/disable the interface.

- *Enabled*: The interface is active and can accept network traffic.
- *Disabled*: The interface is not active and cannot accept traffic.

4. Click **OK**.

To configure an interface in the CLI:

```
config system interface
    edit <name>
        set vdom <VDOM_name>
        set mode {static | dhcp | pppoe}
        set ip <IP_address/netmask>
        set security-mode {none | captive-portal | 802.1X}
        set egress-shaping-profile <profile>
        set device-identification {enable | disable}
        set allowaccess {ping https ssh http snmp telnet fgfm radius-acct probe-response
fabric ftm}
        set eap-supPLICANT {enable | disable}
        set eap-method {peap | tls}
        set eap-identity <identity>
        set eap-password <password>
        set eap-ca-cert <CA_cert>
        set eap-user-cert <user_cert>
        set secondary-IP enable
        config secondaryip
            edit 1
                set ip 9.1.1.2 255.255.255.0
                set allowaccess ping https ssh snmp http
            next
        end
    next
end
```

Configure administrative access to interfaces

You can configure the protocols that administrators can use to access interfaces on the FortiGate. This helps secure access to the FortiGate by restricting access to a limited number of protocols. It helps prevent users from accessing interfaces that you don't want them to access, such as public-facing ports.

As a best practice, you should configure administrative access when you're setting the IP address for a port.

To configure administrative access to interfaces in the GUI:

1. Go to *Network > Interfaces*.
2. Create or edit an interface.
3. In the *Administrative Access* section, select which protocols to enable for *IPv4* and *IPv6 Administrative Access*.

Speed Test	<p>Allow this interface to listen to speed test sender requests.</p> <p>To allow the FortiGate to be configured as speed test server, configure the following:</p> <pre>config system global set speedtest-server {enable disable} end</pre> <p>For more detail, see Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 925.</p>
HTTPS	Allow secure HTTPS connections to the FortiGate GUI through this interface. If configured, this option is enabled automatically.
HTTP	Allow HTTP connections to the FortiGate GUI through this interface. This option can only be enabled if HTTPS is already enabled.
PING	The interface responds to pings. Use this setting to verify your installation and for testing.
FMG-Access	Allow FortiManager authorization automatically during the communication exchanges between FortiManager and FortiGate devices.
SSH	Allow SSH connections to the CLI through this interface.
SNMP	Allow a remote SNMP manager to request SNMP information by connecting to this interface.
FTM	Allow FortiToken Mobile Push (FTM) access.
RADIUS Accounting	Allow RADIUS accounting information on this interface.
Security Fabric Connection	Allow Security Fabric access. This enables FortiTelemetry and CAPWAP.

FEC implementations on 10G, 25G, 40G, and 100G interfaces

Only supported FEC (forward error correction) implementations are allowed to be configured on 10G, 25G, 40G, and 100G interfaces based on the speed that is selected.

- For 1000M, 10G, or 40G interfaces, FEC is not supported and the option is disabled.
- For 25G and 100G interfaces, FEC is automatically set to `cl91-rs-fec` by default.

To configure an interface for FEC:

```
config system interface
    edit <name>
        set speed {10000full | 1000full | 100Gauto | 100Gfull | 25000auto | 25000full | 40000full}
        set mediatype {sr4 | lr4 | cr4}
```

```

        set forward-error-correction {disable | cl91-rs-fec | cl74-fc-fec}
    next
end

```

```

speed {10000full |
      1000full | 100Gauto
      | 100Gfull |
      25000auto |
      25000full |
      40000full}

```

Set the interface speed:

- 10000full: 10G full-duplex
- 1000full: 1000M full-duplex
- 100Gauto: 100G auto-negotiation
- 100Gfull: 100G full-duplex
- 25000auto: 25G auto-negotiation
- 25000full: 25G full-duplex
- 40000full: 40G full-duplex

```

mediatype {sr4 | lr4 |
          cr4}

```

Set the media type to use:

- sr4: short-range transceiver (4-lane)
- lr4: long-range transceiver (4-lane)
- cr4: copper transceiver (4-lane)

```

forward-error-correction
{disable | cl91-rs-
fec | cl74-fc-fec}

```

Set the forward error correction type:

- disable: disable forward error correction
- cl91-rs-fec: Reed-Solomon (FEC CL91)
- cl74-fc-fec: Firecode (FEC CL74)

To change the interface speed from 40G to 100G:

```

config system interface
    edit port26
        set speed 100Gfull
    next
end

```

The speed/mediatype/FEC of port26 will be changed from 40000full/sr4/disable to 100Gfull/sr4/cl91-rs-fec.

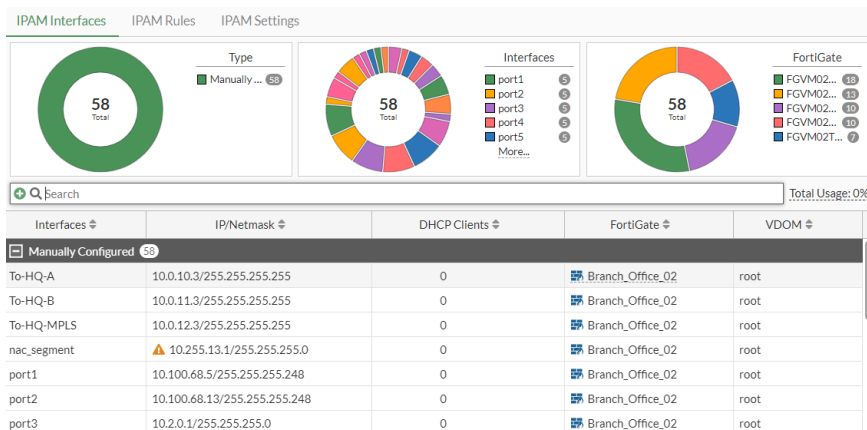

Do you want to continue? (y/n) y

Since the speed changed to 1000G, the `mediatype` setting automatically changes to `sr4`, and the `forward-error-correction` setting automatically changes to `cl91-rs-fec`. When the speed was 40G, the `forward-error-correction` setting was disabled.

Configure IPAM locally on the FortiGate

IPAM (IP address management) is available locally on the FortiGate. A standalone FortiGate, or a Fabric root in the Security Fabric, can act as the IPAM server. Interfaces configured to be auto-managed by IPAM will receive an address from the IPAM server's address/subnet pool. *DHCP Server* is automatically enabled in the GUI, and the address range is populated by IPAM. Users can customize the address pool subnet and the size of a subnet that an interface can request.

IPAM can be configured on the *Network > IPAM* page using the *IPAM Settings*, *IPAM Rules*, and *IPAM Interfaces* tabs.

To configure IPAM settings:

```
config system ipam
    set pool-subnet <class IP and netmask>
    set status {enable | disable}
    config pools
        edit <pool_name>
            set subnet <IP address/netmask>
        next
    end
    config rules
        edit <rule_name>
            set device {<FortiGate_serial_number> | *}
            set interface {<name> | *}
            set pool <pool_name>
        next
    end
end
```

pool-subnet <class IP and netmask>	Set the IPAM pool subnet, class A or class B subnet.
status {enable disable}	Enable/disable IP address management services.
config pools	Set the subnet for the IP pool.
config rules	Set the device, interface, and IP pool for IPAM rules.

In previous FortiOS versions, the `set fortiipam-integration` option was configured under `config system global`.

The following options are available for allocating the subnet size:

```
config system interface
    set managed-subnetwork-size {32 | 64 | 128 | 256 | 512 | 1024 | 2048 | 4096 | 8192 | 16384 | 32768 | 65536}
end
```

Example

In this example, FGT_AA is the Security Fabric root with IPAM enabled. FGT_BB and FGT_CC are downstream Fabric devices and retrieve IPAM information from FGT_AA. The Fabric interface on all FortiGates is port2. FGT_AA acts as the DHCP server, and FGT_BB acts as the DHCP client.

To configure IPAM locally in the Security Fabric:

1. On the root FortiGate, go to *Network > Interfaces* and edit port3.
2. For *Addressing Mode*, select *Auto-Managed by IPAM*. *DHCP Server* is automatically enabled.

Edit Interface

Name: port3

Alias:

Type: Physical Interface

VRF ID: 0

Virtual domain: root

Role: Undefined

Address

Addressing mode: Manual DHCP **Auto-managed by IPAM** One-Arm Sniffer

IPAM is not enabled. [Enable IPAM](#)

IP/Netmask: Not allocated

Network size: 256 (255.255.255.0)

IPAM will allocate an IP subnet with the selected size.

Administrative Access

IPv4: ☐ HTTPS ☐ HTTP ☐ PING ☐ FMG-Access ☐ SSH ☐ SNMP ☐ FTM ☐ RADIUS Accounting ☐ Security Fabric Connection ☐ Speed Test

Receive LLDP: Use VDOM Setting ☐ Enable ☐ Disable

DHCP Server

DHCP status: **Enabled** Disabled

Address range: Not allocated

Netmask: 0.0.0.0

Default gateway: Same as Interface IP Specify

DNS server: Same as System DNS Same as Interface IP Specify

Lease time: 604800 second(s)

FortiGate: FGT_AA

Status: Up

MAC address:

Additional Information: [API Preview](#) [References](#) [Edit in CLI](#)

Documentation: [Online Help](#) [Video Tutorials](#)

3. In this example, IPAM is not enabled yet. Click *Enable IPAM*. The *Subnets Managed by IPAM* pane opens.

4. Select *Enabled*, enter the *Pool subnet* (only class A and B are allowed) and click *OK*. The root FortiGate is now the IPAM server in the Security Fabric.

The following is configured in the backend:

```
config system interface
    edit "port3"
        set vdom "root"
        set ip 172.31.0.1 255.255.0.0
        set type physical
        set device-identification enable
        set snmp-index 5
        set ip-managed-by-fortiipam enable
    end
next
end

config system ipam
    set status enable
end
```

IPAM is managing a 172.31.0.0/16 network and assigned port3 a /24 network by default.

The *IP/Netmask* field in the *Address* section has been automatically assigned a class C IP by IPAM. The *Address range* and *Netmask* fields in the *DHCP Server* section have also been automatically configured by IPAM.

Edit Interface

Name: port3
 Alias:
 Type: Physical Interface
 VRF ID: 0
 Virtual domain: root
 Role: Undefined

Address
 Addressing mode: Manual DHCP **Auto-managed by IPAM** One-Arm Sniffer
 IP/Netmask: 172.31.0.1/255.255.255.0
 Network size: 256 (255.255.255.0)

Administrative Access
 IPv4: ☐ HTTPS ☐ HTTP ☐ PING
☐ FMG-Access ☐ SSH ☐ SNMP
☐ FTM ☐ RADIUS Accounting ☐ Security Fabric Connection
☐ Speed Test
 Receive LLDP: **Use VDOM Setting** Enable Disable

DHCP Server
☒ DHCP Server
 DHCP status: **Enabled** Disabled
 Address range: 172.31.0.1-172.31.0.254
 Netmask: 255.255.255.0
 Default gateway: **Same as Interface IP** Specify
 DNS server: **Same as System DNS** Same as Interface IP Specify
 Lease time: 604800 second(s)

FortiGate
 FGT_AA
 Status: Up
 MAC address:
 Additional Information: API Preview, References, Edit in CLI
 Documentation: Online Help, Video Tutorials

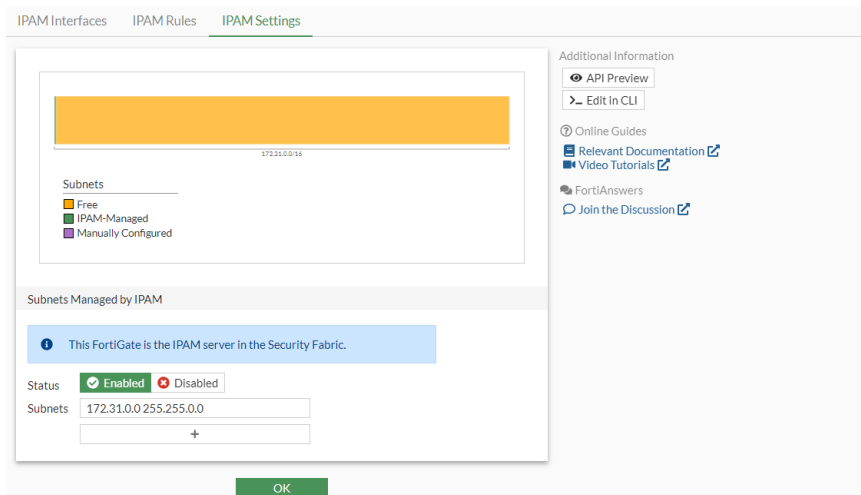

5. Click **OK**.
6. Log in to FGT-BB and set the *Addressing Mode* of port4 to *Auto-Managed by IPAM*. The subnet assigned from the pool on the root is 172.31.1.1/24.
7. Log in to FG_CC and set the *Addressing Mode* of port34 to *Auto-Managed by IPAM*. The subnet assigned from the pool on the root is 172.31.2.1/24.

Any interface on a downstream FortiGate can be managed by the IPAM server. The interface does not have to be directly connected to the Fabric root FortiGate.

To edit the IPAM subnet:

1. Go to *Network > IPAM > IPAM Settings*.
2. Edit the pool subnet if needed.

3. Click **OK**.

On downstream FortiGates, the settings on the *Network > IPAM > IPAM Settings* tab cannot be changed if IPAM is enabled on the root FortiGate.

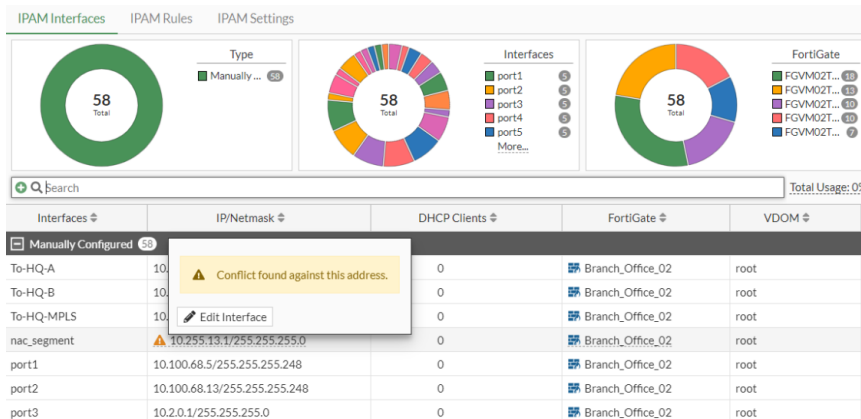

Go to *Network > IPAM > IPAM Interfaces* to view the subnet allocations (port34, port3, and port3) and DHCP lease information. On FGT_BB, port3 is a DHCP client and the DHCP server interface (FGT_AA port3) is managed by IPAM, so it is displayed in the *Manually Configured* section.

IPAM conflict markers

The *IPAM Interfaces* tab displays conflict markers when there are IP pool IP address conflicts with manually configured IP addresses. Administrators can use the *Edit Interface* dialog to manually resolve the conflict.

To resolve conflicts in the GUI:

1. Go to *Network > IPAM > IPAM Interfaces*.
2. Hover your mouse over the conflict marker. The conflict marker information is displayed.

3. Click **Edit Interface**. The *Edit Interface* pane opens.

4. Enter a new IP address and netmask in the *IP/Netmask* field.
5. Click **OK**. A confirmation message is displayed.
6. Click **OK**.

Diagnostics

Use the following commands to view IPAM related diagnostics.

To view the largest available subnet size:

```
# diagnose sys ipam largest-available-subnet
Largest available subnet is a /17.
```

To verify IPAM allocation information:

```
# diagnose sys ipam dump-ipams-entries
IPAM Entries: (sn, vdom, interface, subnet/mask, flag)
F140EP4Q17000000 root port34 172.31.2.1/24 0
FG5H1E5818900001 root port3 172.31.0.1/24 0
FG5H1E5818900002 root port4 172.31.1.1/24 0
FG5H1E5818900003 root port3 172.31.0.2/24 1
```

To verify the available subnets:

```
# diagnose sys ipam dump-ipams-free-subnets
IPAM free subnets: (subnet/mask)
172.31.3.0/24
172.31.4.0/22
172.31.8.0/21
172.31.16.0/20
172.31.32.0/19
172.31.64.0/18
172.31.128.0/17
```

To remove a device from IPAM in the Security Fabric:

```
# diagnose sys ipam delete-device-from-ipams F140EP4Q17000000
Successfully removed device F140EP4Q17000000 from ipam
```

Interface MTU packet size

Changing the maximum transmission unit (MTU) on FortiGate interfaces changes the size of transmitted packets. Most FortiGate device's physical interfaces support jumbo frames that are up to 9216 bytes, but some only support 9000 or 9204 bytes.

To avoid fragmentation, the MTU should be the same as the smallest MTU in all of the networks between the FortiGate and the destination. If the packets sent by the FortiGate are larger than the smallest MTU, then they are fragmented, slowing down the transmission. Packets with the DF flag set in the IPv4 header are dropped and not fragmented.

On many network and endpoint devices, the path MTU is used to determine the smallest MTU and to transmit packets within that size.

- ASIC accelerated FortiGate interfaces, such as NP6, NP7, and SOC4 (np6xlite), support MTU sizes up to 9216 bytes.
- FortiGate VMs can have varying maximum MTU sizes, depending on the underlying interface and driver.
- Virtual interfaces, such as VLAN interfaces, inherit their MTU size from their parent interface.

To verify the supported MTU size:

```
config system interface
    edit <interface>
        set mtu-override enable
        set mtu <integer>
    next
end
```

To change the MTU size:

```
config system interface
    edit <interface>
        set mtu-override enable
        set mtu <max bytes>
    next
end
```

Maximum MTU size on a path

To manually test the maximum MTU size on a path, you can use the ping command on a Windows computer.

For example, you can send ICMP packets of a specific size with a DF flag, and iterate through increasing sizes until the ping fails.

- The `-f` option specifies the Do not Fragment (DF) flag.
- The `-l` option specifies the length, in bytes, of the Data field in the echo Request messages. This does not include the 8 bytes for the ICMP header and 20 bytes for the IP header. Therefore, if the maximum MTU is 1500 bytes, then the maximum supported data size is: $1500 - 8 - 20 = 1472$ bytes.

To determine the maximum MTU size on a path:

1. In Windows command prompt, try a likely MTU size:

```
>ping 4.2.2.1 -l 1472 -f
Pinging 4.2.2.1 with 1472 bytes of data:
Reply from 4.2.2.1: bytes=1472 time=41ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=42ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=103ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=38ms TTL=52

Ping statistics for 4.2.2.1:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 38ms, Maximum = 103ms, Average = 56ms
```

2. Increase the size and try the ping again:

```
>ping 4.2.2.1 -l 1473 -f
Pinging 4.2.2.1 with 1473 bytes of data:
Request timed out.

Ping statistics for 4.2.2.1:
    Packets: Sent = 1, Received = 0, Lost = 1 (100% loss),
```

The second test fails, so the maximum MTU size on the path is 1472 bytes + 8-byte ICMP header + 20-byte IP header = 1500 bytes

Maximum segment size

The TCP maximum segment size (MSS) is the maximum amount of data that can be sent in a TCP segment. The MSS is the MTU size of the interface minus the 20 byte IP header and 20 byte TCP header. By reducing the TCP MSS, you can effectively reduce the MTU size of the packet.

The TCP MSS can be configured in a firewall policy (see [Configurations in the CLI on page 1183](#)), or directly on an interface.

To configure the MSS on an interface:

```
config system interface
    edit "wan2"
        set vdom "root"
        set mode dhcp
        set allowaccess ping fgfm
        set type physical
        set tcp-mss 1448
        set role wan
    next
end
```

One-arm sniffer

You can use a one-arm sniffer to configure a physical interface as a one-arm intrusion detection system (IDS). Traffic sent to the interface is examined for matches to the configured security profile. The matches are logged, and then all received traffic is dropped. Sniffing only reports on attacks; it does not deny or influence traffic.

You can also use the one-arm sniffer to configure the FortiGate to operate as an IDS appliance to sniff network traffic for attacks without actually processing the packets. To configure a one-arm IDS, enable sniffer mode on a physical interface and connect the interface to the SPAN port of a switch or a dedicated network tap that can replicate the traffic to the FortiGate.

If the one-arm sniffer option is not available, this means the interface is in use. Ensure that the interface is not selected in any firewall policies, routes, virtual IPs, or other features where a physical interface is specified. The option also does not appear if the role is set to WAN. Ensure the role is set to LAN, DMZ, or undefined.

The following table lists some of the one-arm sniffer settings you can configure:

Field	Description
Security Profiles	<p>The following profiles are configurable in the GUI and CLI:</p> <ul style="list-style-type: none"> • Antivirus • Web filter • Application control • IPS • File filter <p>The following profiles are only configurable in the CLI:</p> <ul style="list-style-type: none"> • Email filter • DLP • IPS DoS

Each security profile has a predefined profile for *One-Arm Sniffer* called *sniffer-profile*. The *sniffer-profile* can be viewed or edited from the GUI through the *Edit Interface* page only. Please refer to the [Example configuration on page 178](#) for a demonstration.

CPU usage and packet loss

Traffic scanned on the one-arm sniffer interface is processed by the CPU, even if there is an SPU, such as NPU or CP, present. The one-arm sniffer may cause higher CPU usage and perform at a lower level than traditional inline scanning, which uses NTurbo or CP to accelerate traffic when present.

The absence of high CPU usage does not indicate the absence of packet loss. Packet loss may occur due to the capacity of the TAP devices hitting maximum traffic volume during mirroring, or on the FortiGate when the kernel buffer size is exceeded and it is unable to handle bursts of traffic.

Example configuration

The following example shows how to configure a file filter profile that blocks PDF and RAR files used in a one-arm sniffer policy.

To configure a one-arm sniffer policy in the GUI:

1. Go to *Network > Interfaces* and double-click a physical interface to edit it.
2. For *Role*, select either *LAN*, *DMZ*, or *Undefined*.
3. For *Addressing Mode*, select *One-Arm Sniffer*.

Q

Rule	Comments	Traffic	Protocols	Match Files	Action	File Types
file		Both	CIFS FTP +4	Any	Block	pdf rar

OK Cancel

- Click **OK** to save the interface settings.
- Go to **Log & Report > Security Events** to view the *File Filter* logs.

Date/Time	Service	Action	URL	File Name	Matched file name	File Type	Matched file type	Filter Name
9 minutes ago	FTP	passthrough		hello2.pdf		pdf		file
10 minutes ago	FTP	passthrough		test.rar		rar		file

To configure a one-arm sniffer policy in the CLI:

- Configure the interface:

```
config system interface
    edit "s1"
        set vdom "root"
        set ips-sniffer-mode enable
        set type physical
        set role undefined
        set snmp-index 31
    next
end
```

- Configure the file filter profile:

```
config file-filter profile
    edit "sniffer-profile"
        set comment "File type inspection."
        config rules
            edit "1"
                set protocol http ftp smtp imap pop3 cifs
```

```
        set action block
        set file-type "pdf" "rar"
    next
end
next
end
```

3. Configure the firewall sniffer policy:

```
config firewall sniffer
    edit 1
        set interface "s1"
        set file-filter-profile-status enable
        set file-filter-profile "sniffer-profile"
    next
end
```

4. View the log:

```
# execute log filter category 19
# execute log display
1 logs found.
1 logs returned.
```

Interface migration wizard

The *Integrate Interface* option on the *Network > Interfaces* page helps migrate a physical port into another interface or interface type such as aggregate, software switch, redundant, zone, or SD-WAN zone. The FortiGate will migrate object references either by replacing the existing instance with the new interface, or deleting the existing instance based on the user's choice. Users can also change the VLAN ID of existing VLAN sub-interface or FortiSwitch VLANs.

The interface migration wizard does not support turning an aggregate, software switch, redundant, zone, or SD-WAN zone interface back into a physical interface.

Integrating an interface

In this example, a DHCP server interface is integrated into a newly created redundant interface, which transfers the DHCP server to a redundant interface.

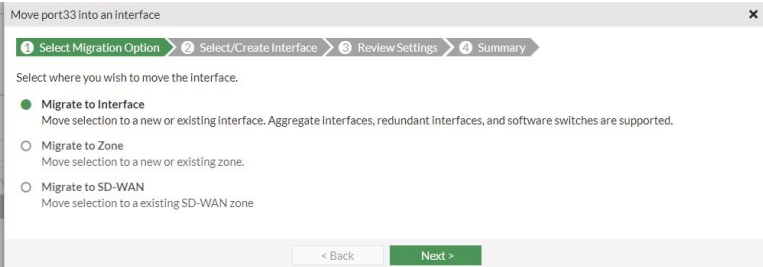

To integrate an interface:

1. Go to *Network > Interfaces* and select an interface in the list.
2. Click *Integrate Interface*. The wizard opens.

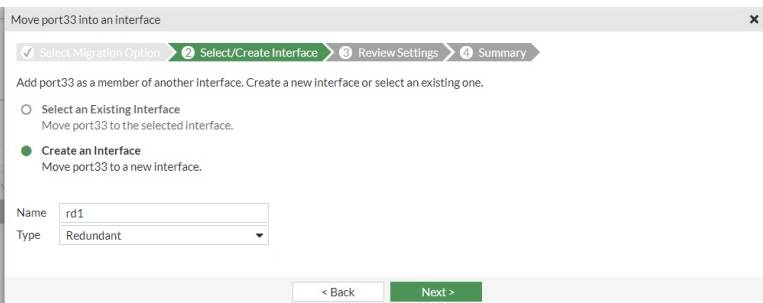

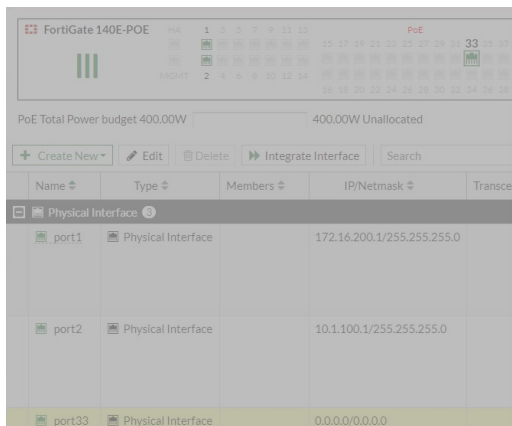

Alternatively, select an interface in the list. Then right-click and select *Integrate Interface*.

3. Select *Migrate to Interface* and click *Next*.

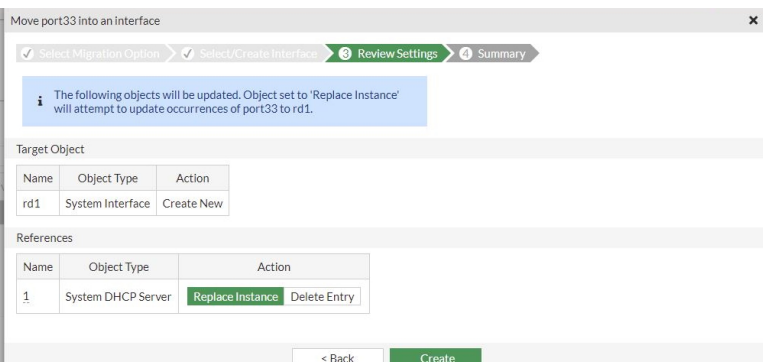

4. Select *Create an Interface*. Enter a name (*rd1*) and set the *Type* to *Redundant*.

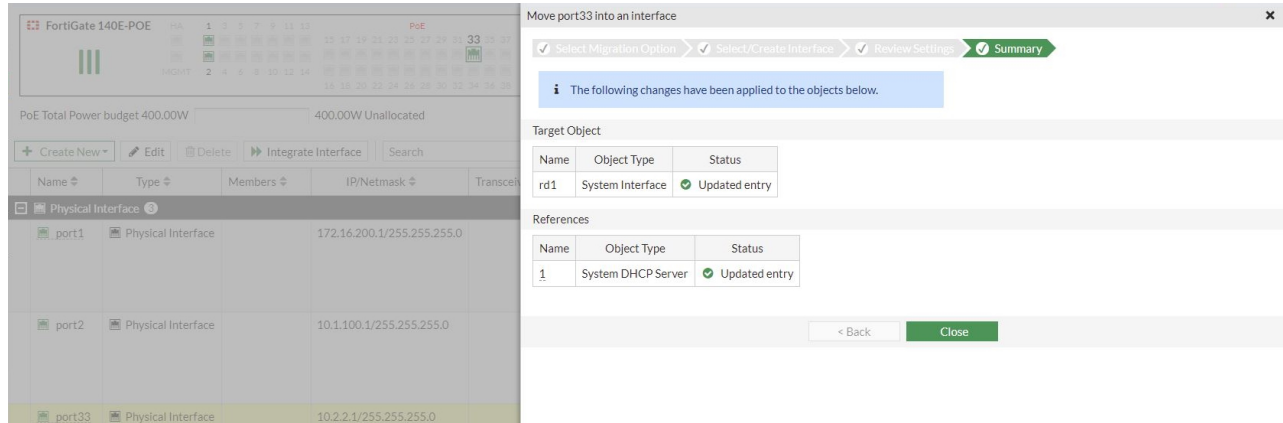

5. Click *Next*. The *References* section lists the associated services with options to *Replace Instance* or *Delete Entry*.

6. For the DHCP server *Action*, select *Replace Instance* and click *Create*.

7. The migration occurs automatically and the statuses for the object and reference change to *Updated entry*. Click *Close*.

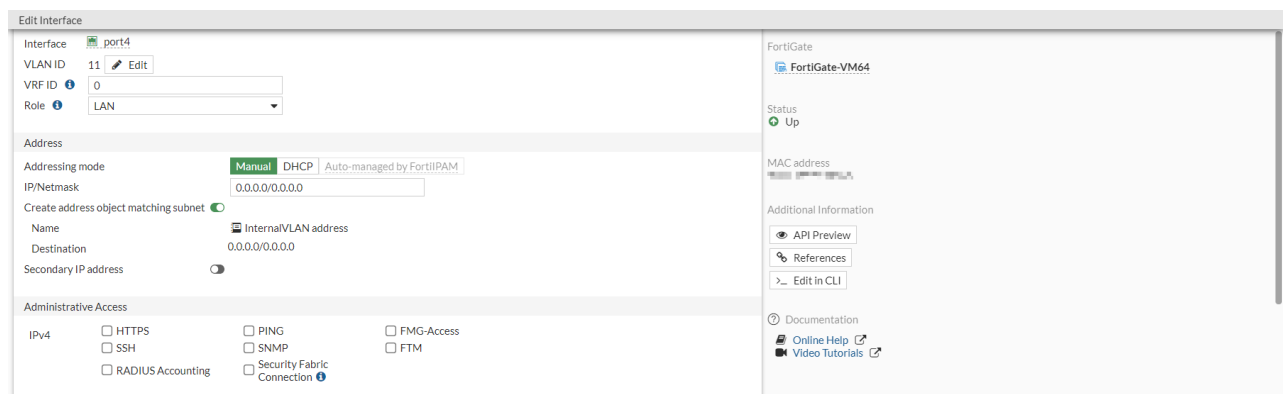

Changing the VLAN ID

In this example, the VLAN ID of *Internal/VLAN* is changed from 11 to 22.

To change the VLAN ID:

1. Go to *Network > Interfaces* and edit an existing interface.
2. Beside the *VLAN ID* field, click *Edit*. The *Update VLAN ID* window opens.

3. Enter the new ID (22) and click *Next*.

Captive portals

A captive portal is used to enforce authentication before web resources can be accessed. Until a user authenticates successfully, any HTTP request returns the authentication page. After successfully authenticating, a user can access the requested URL and other web resources, as permitted by policies. The captive portal can also be configured to only allow access to members of specific user groups.

Captive portals can be hosted on the FortiGate or an external authentication server. They can be configured on any network interface, including VLAN and WiFi interfaces. On a WiFi interface, the access point appears open, and the client can connect to access point with no security credentials, but then sees the captive portal authentication page. See [Captive Portal Security](#), in the [FortiWiFi and FortiAP Configuration Guide](#) for more information.

All users on the interface are required to authenticate. Exemption lists can be created for devices that are unable to authenticate, such as a printer that requires access to the internet for firmware upgrades.

To configure a captive portal in the GUI:

1. Go to **Network > Interfaces** and edit the interface that the users connect to. The interface *Role* must be *LAN* or *Undefined*.
2. Enable *Security mode*.

3. Configure the following settings, then click **OK**.

Authentication Portal

Configure the location of the portal:

- *Local*: the portal is hosted on the FortiGate unit.

	<ul style="list-style-type: none"> • <i>External</i>: enter the FQDN or IP address of external portal.
User access	<p>Select if the portal applies to all users, or selected user groups:</p> <ul style="list-style-type: none"> • <i>Restricted to Groups</i>: restrict access to the selected user groups. The <i>Login page</i> is shown when a user tries to log in to the captive portal. • <i>Allow all</i>: all users can log in, but access will be defined by relevant policies. The <i>Disclaimer page</i> is shown when a user tried to log in to the captive portal.
Customize portal messages	<p>Enable to use custom portal pages, then select a replacement message group. See Custom captive portal pages on page 188.</p>
Exempt sources	<p>Select sources that are exempt from the captive portal.</p> <p>Each exemption is added as a rule in an automatically generated exemption list.</p>
Exempt destinations/services	<p>Select destinations and services that are exempt from the captive portal.</p> <p>Each exemption is added as a rule in an automatically generated exemption list.</p>
Redirect after Captive Portal	<p>Configure website redirection after successful captive portal authentication:</p> <ul style="list-style-type: none"> • <i>Original Request</i>: redirect to the initially browsed to URL . • <i>Specific URL</i>: redirect to the specified URL.

To configure a captive portal in the CLI:

1. If required, create a security exemption list:

```
config user security-exempt-list
  edit <list>
    config rule
      edit 1
        set srcaddr <source(s)>
        set dstaddr <source(s)>
        set service <service(s)>
      next
      edit 2
        set srcaddr <source(s)>
        set dstaddr <source(s)>
        set service <service(s)>
      next
    end
  next
end
```

2. Configure captive portal authentication on the interface:

```
config system interface
  edit <interface>
    set security-mode {none | captive-portal}
    set security-external-web <string>
    set replacemsg-override-group <group>
    set security-redirect-url <string>
    set security-exempt-list <list>
    set security-groups <group(s)>
  end
```

```

    next
end

```

Custom captive portal pages

Portal pages are HTML files that can be customized to meet user requirements.

Most of the text and some of the HTML in the message can be changed. Tags are enclosed by double percent signs (%%); most of them should not be changed because they might carry information that the FortiGate unit needs. For information about customizing replacement messages, see [Modifying replacement messages on page 2671](#).

The images on the pages can be replaced. For example, your organization's logo can replace the Fortinet logo. For information about uploading and using new images in replacement messages, see [Replacement message images on page 2673](#).

The following pages are used by captive portals:

Login Page	Requests user credentials. The %%QUESTION%% tag provides the <i>Please enter the required information to continue.</i> text. This page is shown to users that are trying to log in when <i>User access</i> is set to <i>Restricted to Groups</i> .
Login Failed Page	Reports that incorrect credentials were entered, and requests correct credentials. The %%FAILED_MESSAGE%% tag provides the <i>Firewall authentication failed. Please try again.</i> text.
Disclaimer Page	A statement of the legal responsibilities of the user and the host organization that the user must agree to before proceeding. This page is shown users that are trying to log in when <i>User access</i> is set to <i>Allow all</i> .
Declined Disclaimer Page	Shown if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

Physical interface

A FortiGate has several physical interfaces that can connect to Ethernet or optical cables. Depending on the FortiGate model, it can have a varying combination of Ethernet, small form-factor pluggable (SFP), and enhanced small form-factor pluggable (SFP+) interfaces.

The port names, as labeled on the FortiGate, appear in the interfaces list on the *Network > Interfaces* page. Hover the cursor over a port to view information, such as the name and the IP address.

Refer to [Configuring an interface](#) for basic GUI and CLI configuration steps.

Displaying transceiver status information for SFP and SFP+ interfaces

Transceiver status information for SFP and SFP+ interfaces installed on the FortiGate can be displayed in the GUI and CLI. For example, the type, vendor name, part number, serial number, and port name. The CLI output includes additional information that can be useful for diagnosing transmission problems, such as the temperature, voltage, and optical transmission power.

To view transceiver status information in the GUI:

1. Go to *Network > Interfaces*. The *Transceiver* column is visible in the table, which displays the transceiver vendor name and part number.
2. Hover the cursor over a transceiver to view more information.

To view transceiver status information in the CLI:

```
# get system interface transceiver
Interface port9 - SFP/SFP+
  Vendor Name   :      FINISAR CORP.
  Part No.      :      FCLF-8521-3
  Serial No.    :      PMS***

++ : high alarm, + : high warning, - : low warning, -- : low alarm, ? : suspect.

VLAN

Virtual local area networks (VLANs) multiply the capabilities of your FortiGate and can also provide added network security. VLANs use ID tags to logically separate devices on a network into smaller broadcast domains. These smaller

domains forward packets only to devices that are part of that VLAN domain. This reduces traffic and increases network security.

VLANs in NAT mode

In NAT mode, the FortiGate unit functions as a layer-3 device. In this mode, the FortiGate unit controls the flow of packets between VLANs and can also remove VLAN tags from incoming VLAN packets. The FortiGate unit can also forward untagged packets to other networks such as the Internet.

In NAT mode, the FortiGate unit supports VLAN trunk links with IEEE 802.1Q-compliant switches or routers. The trunk link transports VLAN-tagged packets between physical subnets or networks. When you add VLAN subinterfaces to the FortiGate's physical interfaces, the VLANs have IDs that match the VLAN IDs of packets on the trunk link. The FortiGate unit directs packets with VLAN IDs to subinterfaces with matching IDs.

You can define VLAN subinterfaces on all FortiGate physical interfaces. However, if multiple virtual domains are configured on the FortiGate unit, you only have access to the physical interfaces on your virtual domain. The FortiGate unit can tag packets leaving on a VLAN subinterface. It can also remove VLAN tags from incoming packets and add a different VLAN tag to outgoing packets.

Normally in VLAN configurations, the FortiGate unit's internal interface is connected to a VLAN trunk, and the external interface connects to an Internet router that is not configured for VLANs. In this configuration, the FortiGate unit can apply different policies for traffic on each VLAN interface connected to the internal interface, which results in less network traffic and better security.

Sample topology

In this example, two different internal VLAN networks share one interface on the FortiGate unit and share the connection to the Internet. This example shows that two networks can have separate traffic streams while sharing a single interface. This configuration can apply to two departments in a single company or to different companies.

There are two different internal network VLANs in this example. VLAN_100 is on the 10.1.1.0/255.255.255.0 subnet, and VLAN_200 is on the 10.1.2.0/255.255.255.0 subnet. These VLANs are connected to the VLAN switch.

The FortiGate internal interface connects to the VLAN switch through an 802.1Q trunk. The internal interface has an IP address of 192.168.110.126 and is configured with two VLAN subinterfaces (VLAN_100 and VLAN_200). The external interface has an IP address of 172.16.21.2 and connects to the Internet. The external interface has no VLAN subinterfaces.

When the VLAN switch receives packets from VLAN_100 and VLAN_200, it applies VLAN ID tags and forwards the packets of each VLAN both to local ports and to the FortiGate unit across the trunk link. The FortiGate unit has policies that allow traffic to flow between the VLANs, and from the VLANs to the external network.

Sample configuration

In this example, both the FortiGate unit and the Cisco 2950 switch are installed and connected and basic configuration has been completed. On the switch, you need access to the CLI to enter commands. No VDOMs are enabled in this example.

General configuration steps include:

1. [Configure the external interface.](#)
2. [Add two VLAN subinterfaces to the internal network interface.](#)
3. [Add firewall addresses and address ranges for the internal and external networks.](#)
4. [Add security policies to allow:](#)
 - the VLAN networks to access each other.
 - the VLAN networks to access the external network.

To configure the external interface:

```
config system interface
    edit external
        set mode static
        set ip 172.16.21.2 255.255.255.0
    next
end
```

To add VLAN subinterfaces:

```
config system interface
    edit VLAN_100
        set vdom root
        set interface internal
        set type vlan
```

```
        set vlanid 100
        set mode static
        set ip 10.1.1.1 255.255.255.0
        set allowaccess https ping
    next
    edit VLAN_200
        set vdom root
        set interface internal
        set type vlan
        set vlanid 200
        set mode static
        set ip 10.1.2.1 255.255.255.0
        set allowaccess https ping
    next
end
```

To add the firewall addresses:

```
config firewall address
    edit VLAN_100_Net
        set type ipmask
        set subnet 10.1.1.0 255.255.255.0
    next
    edit VLAN_200_Net
        set type ipmask
        set subnet 10.1.2.0 255.255.255.0
    next
end
```

To add security policies:

Policies 1 and 2 do not need NAT enabled, but policies 3 and 4 do need NAT enabled.

```
config firewall policy
    edit 1
        set srcintf VLAN_100
        set srcaddr VLAN_100_Net
        set dstintf VLAN_200
        set dstaddr VLAN_200_Net
        set schedule always
        set service ALL
        set action accept
        set nat disable
        set status enable
    next
    edit 2
        set srcintf VLAN_200
        set srcaddr VLAN_200_Net
        set dstintf VLAN_100
        set dstaddr VLAN_100_Net
        set schedule always
        set service ALL
        set action accept
        set nat disable
        set status enable
    next
```

```
edit 3
    set srcintf VLAN_100
    set srcaddr VLAN_100_Net
    set dstintf external
    set dstaddr all
    set schedule always
    set service ALL
    set action accept
    set nat enable
    set status enable
next
edit 4
    set srcintf VLAN_200
    set srcaddr VLAN_200_Net
    set dstintf external
    set dstaddr all
    set schedule always
    set service ALL
    set action accept
    set nat enable
    set status enable
next
end
```

VLANs in transparent mode

In transparent mode, the FortiGate unit behaves like a layer-2 bridge but can still provide services such as antivirus scanning, web filtering, spam filtering, and intrusion protection to traffic. Some limitations of transparent mode is that you cannot use SSL VPN, PPTP/L2TP VPN, DHCP server, or easily perform NAT on traffic. The limits in transparent mode apply to IEEE 802.1Q VLAN trunks passing through the unit.

You can insert the FortiGate unit operating in transparent mode into the VLAN trunk without making changes to your network. In a typical configuration, the FortiGate unit internal interface accepts VLAN packets on a VLAN trunk from a VLAN switch or router connected to internal network VLANs. The FortiGate external interface forwards VLAN-tagged packets through another VLAN trunk to an external VLAN switch or router and on to external networks such as the Internet. You can configure the unit to apply different policies for traffic on each VLAN in the trunk.

To pass VLAN traffic through the FortiGate unit, you add two VLAN subinterfaces with the same VLAN ID, one to the internal interface and the other to the external interface. You then create a security policy to permit packets to flow from the internal VLAN interface to the external VLAN interface. If required, create another security policy to permit packets to flow from the external VLAN interface to the internal VLAN interface. Typically in transparent mode, you do not permit packets to move between different VLANs. Network protection features such as spam filtering, web filtering, and anti-virus scanning, are applied through the UTM profiles specified in each security policy, enabling very detailed control over traffic.

When the FortiGate unit receives a VLAN-tagged packet on a physical interface, it directs the packet to the VLAN subinterface with the matching VLAN ID. The VLAN tag is removed from the packet and the FortiGate unit then applies security policies using the same method it uses for non-VLAN packets. If the packet exits the FortiGate unit through a VLAN subinterface, the VLAN ID for that subinterface is added to the packet and the packet is sent to the corresponding physical interface.

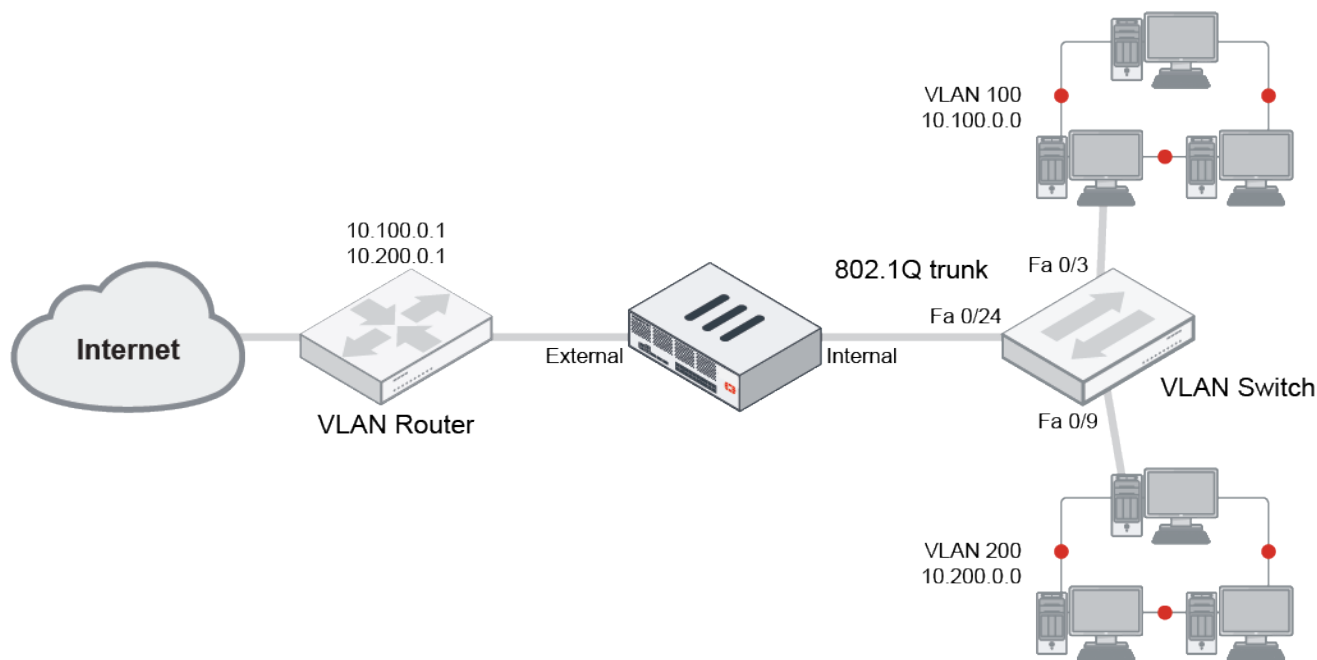

Sample topology

In this example, the FortiGate unit is operating in transparent mode and is configured with two VLANs: one with an ID of 100 and the other with ID 200. The internal and external physical interfaces each have two VLAN subinterfaces, one for VLAN_100 and one for VLAN_200.

The IP range for the internal VLAN_100 network is 10.100.0.0/255.255.0.0, and for the internal VLAN_200 network is 10.200.0.0/255.255.0.0.

The internal networks are connected to a Cisco 2950 VLAN switch which combines traffic from the two VLANs onto one in the FortiGate unit's internal interface. The VLAN traffic leaves the FortiGate unit on the external network interface, goes on to the VLAN switch, and on to the Internet. When the FortiGate unit receives a tagged packet, it directs it from the incoming VLAN subinterface to the outgoing VLAN subinterface for that VLAN.

In this example, we create a VLAN subinterface on the internal interface and another one on the external interface, both with the same VLAN ID. Then we create security policies that allow packets to travel between the VLAN_100_int interface and the VLAN_100_ext interface. Two policies are required: one for each direction of traffic. The same is required between the VLAN_200_int interface and the VLAN_200_ext interface, for a total of four security policies.

Sample configuration

There are two main steps to configure your FortiGate unit to work with VLANs in transparent mode:

1. [Add VLAN subinterfaces.](#)
2. [Add security policies.](#)

You can also configure the protection profiles that manage antivirus scanning, web filtering, and spam filtering.

To add VLAN subinterfaces:

```
config system interface
    edit VLAN_100_int
        set type vlan
```

```
        set interface internal
        set vlanid 100
    next
    edit VLAN_100_ext
        set type vlan
        set interface external
        set vlanid 100
    next
    edit VLAN_200_int
        set type vlan
        set interface internal
        set vlanid 200
    next
    edit VLAN_200_ext
        set type vlan
        set interface external
        set vlanid 200
    next
end
```

To add security policies:

```
config firewall policy
    edit 1
        set srcintf VLAN_100_int
        set srcaddr all
        set dstintf VLAN_100_ext
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 2
        set srcintf VLAN_100_ext
        set srcaddr all
        set dstintf VLAN_100_int
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 3
        set srcintf VLAN_200_int
        set srcaddr all
        set dstintf VLAN_200_ext
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 4
        set srcintf VLAN_200_ext
        set srcaddr all
        set dstintf VLAN_200_int
        set dstaddr all
        set action accept
```

```
        set schedule always
        set service ALL
    next
end
```

Virtual VLAN switch

The hardware switch ports on FortiGate models that support virtual VLAN switches can be used as a layer 2 switch. Virtual VLAN switch mode allows 802.1Q VLANs to be assigned to ports, and the configuration of one interface as a trunk port.

The following FortiGate series are supported in FortiOS 7.4: 60F, 80F, 100E, 100F, 140E, 200F, 300E, 400E, 1100E, 1800F, 2600F, 3500F, 4200F, and 4400F.

The `virtual-switch-vlan` option must be enabled in the CLI to configure VLAN switch mode from the GUI or CLI.

To enable VLAN switches:

```
config system global
    set virtual-switch-vlan enable
end
```

After this setting is enabled, any previously configured hardware switches will appear in the *Network > Interfaces* page under *VLAN Switch*.

To enable VLAN switch mode in the GUI:

1. Go to *System > Settings*.
2. In the *View Settings* section, enable *VLAN switch mode*.
3. Click *Apply*.

Basic configurations

Hardware switch ports can be configured as either a VLAN switch port or a trunk port. The available interfaces and allowable VLAN IDs that can be used depend on the FortiGate model. It is recommended to remove ports from the default VLAN switch before you begin configurations.

To create a new VLAN and assign ports in the GUI:

1. Go to *Network > Interfaces* and click *Create New > Interface*.
2. Enter a name and configure the following:
 - a. Set the *Type* to *VLAN Switch*.
 - b. Enter a *VLAN ID*.
 - c. Click the **+** and add the *Interface Members*.
 - d. Configure the *Address* and *Administrative Access* settings as needed.
3. Click *OK*.

To create a new VLAN and assign ports in the CLI:**1. Configure the VLAN:**

```
config system virtual-switch
  edit "VLAN10"
    set physical-switch "sw0"
    set vlan 10
    config port
      edit "internal1"
      next
      edit "internal2"
      next
    end
  next
end
```

2. Configure the VLAN switch interface addressing:

```
config system interface
  edit "VLAN10"
    set vdom "root"
    set ip 192.168.10.99 255.255.255.0
    set allowaccess ping https ssh snmp http fgfm
    set type hard-switch
  next
end
```

To designate an interface as a trunk port:

```
config system interface
  edit internal5
    set trunk enable
  next
end
```

Example 1: HA using a VLAN switch

In this example, two FortiGates in an HA cluster are connected to two ISP routers. Instead of connecting to external L2 switches, each FortiGate connects to each ISP router on the same hardware switch port on the same VLAN. A trunk port connects the two FortiGates to deliver the 802.1Q tagged traffic to the other. A full mesh between the FortiGate cluster and the ISP routers is achieved where no single point of failure will cause traffic disruptions.

This example assumes that the HA settings are already configured. The interface and VLAN switch settings are identical between cluster members and synchronized. See [HA using a hardware switch to replace a physical switch on page 2559](#) for a similar example that does not use a VLAN switch.

To configure the VLAN switches:

1. Configure the ISP interfaces with the corresponding VLAN IDs:

```

config system virtual-switch
    edit "ISP1"
        set physical-switch "sw0"
        set vlan 2951
        config port
            edit "port1"
            next
        end
    next
    edit "ISP2"
        set physical-switch "sw0"
        set vlan 2952
        config port
            edit "port2"
            next
        end
    next
end

```

2. Configure the VLAN switch interface addressing:

```

config system interface
    edit "ISP1"
        set vdom "root"
        set ip 192.168.10.99 255.255.255.0
        set allowaccess ping
        set type hard-switch
    next
    edit "ISP2"
        set vdom "root"
    next
end

```

```
        set ip 192.168.20.99 255.255.255.0
        set allowaccess ping
        set type hard-switch
    next
end
```

3. Designate port15 as the trunk port:

```
config system interface
    edit port15
        set trunk enable
    next
end
```

4. Configure firewall policies to allow outgoing traffic on the ISP1 and ISP2 interfaces:

```
config firewall policy
    edit 1
        set srcintf "port11"
        set dstintf "ISP1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
    edit 2
        set srcintf "port11"
        set dstintf "ISP2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Example 2: LAN extension

In this example, two hardware switch ports are assigned VLAN10, and two ports are assigned VLAN20 on FortiGate B. The wan2 interface is designated as the trunk port, and is connected to the upstream FortiGate A. The corresponding VLAN subinterfaces VLAN10 and VLAN20 on the upstream FortiGate allow further access to other networks.

The available interfaces and VLAN IDs varies between FortiGate models. The FortiGate B in this example is a 60F model.

To configure FortiGate B:

1. Configure the VLAN interfaces:

```

config system virtual-switch
  edit "VLAN10"
    set physical-switch "sw0"
    set vlan 10
    config port
      edit "internal1"
      next
      edit "internal2"
      next
    end
  next
  edit "VLAN20"
    set physical-switch "sw0"
    set vlan 20
    config port
      edit "internal3"
      next
      edit "internal4"
      next
    end
  next
end

```

2. Configure the VLAN switch interface addressing:

```

config system interface
  edit "VLAN10"
    set vdom "root"
    set ip 192.168.10.99 255.255.255.0
    set allowaccess ping https ssh snmp http fgfm
  
```

```
        set type hard-switch
    next
    edit "VLAN20"
        set vdom "root"
        set ip 192.168.20.99 255.255.255.0
        set allowaccess ping https ssh snmp http fgfm
        set type hard-switch
    next
end
```

3. Designate wan2 as the trunk port:

```
config system interface
    edit wan2
        set trunk enable
    next
end
```

To configure FortiGate A:

1. Configure the VLAN subinterfaces:

```
config system interface
    edit "VLAN10"
        set ip 192.168.10.98 255.255.255.0
        set allowaccess ping https ssh
        set role lan
        set interface "dmz"
        set vlanid 10
    next
    edit "VLAN20"
        set ip 192.168.20.98 255.255.255.0
        set allowaccess ping https ssh
        set role lan
        set interface "dmz"
        set vlanid 20
    next
end
```

2. Configure the DHCP server on VLAN10:

```
config system dhcp server
    edit 0
        set dns-service default
        set default-gateway 192.168.10.98
        set netmask 255.255.255.0
        set interface "VLAN10 "
        config ip-range
            edit 1
                set start-ip 192.168.10.100
                set end-ip 192.168.10.254
            next
        end
        set timezone-option default
    next
end
```

3. Configure firewall policies that allow traffic from the VLAN10 and VLAN20 interfaces to the internet:

```
config firewall policy
    edit 0
        set name "VLAN10-out"
        set srcintf "VLAN10"
        set dstintf "wan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
    edit 0
        set name "VLAN20-out"
        set srcintf "VLAN20"
        set dstintf "wan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

To test the connection:

1. Connect a PC to internal1 on FortiGate B.
2. Verify that it receives an IP address from FortiGate A's DHCP server.
3. From the PC, ping FortiGate B on 192.168.10.99.
4. Ping FortiGate A on 192.168.10.98.
5. Connect to the internet. Traffic is allowed by the VLAN10-out policy.

QinQ 802.1Q in 802.1ad

QinQ (802.1ad) allows multiple VLAN tags to be inserted into a single frame, and can be configured on supported FortiGate devices.

In this example, the customer connects to a provider that uses 802.1ad double-tagging to separate their customer VLANs. The FortiGate connecting to the provider double-tags its frames with an outer provider-tag (S-Tag) and an inner customer-tag (C-Tag).

The customer identifies itself with the provider-tag (S-Tag) 232 and uses the customer-tag (C-Tag) 444 for traffic to its VLAN.

To configure the interfaces:

1. Configure the interface to the provider that uses the outer tag (S-Tag):

```
config system interface
  edit "vlan-8021ad"
    set vdom "root"
    set vlan-protocol 8021ad
    set device-identification enable
    set role lan
    set snmp-index 47
    set interface "PORT"
    set vlanid 232
  next
end
```

2. Configure a dynamic VLAN interface that uses the inner tag (C-Tag):

```
config system interface
  edit "DVLAN"
    set vdom "vdom1"
    set device-identification enable
    set role lan
    set snmp-index 48
    set interface "vlan-8021ad"
    set vlanid 444
  next
end
```

QinQ 802.1Q in 802.1Q

QinQ (802.1Q in 802.1Q) is supported for FortiGate VM models, where multiple VLAN tags can be inserted into a single frame.

In this example, the FortiGate VM is connected to a provider vSwitch and then a customer switch. The FortiGate encapsulates the frame with an outer 802.1Q tag of VLAN 100 and an inner 802.1Q tag of VLAN 200; port5 is used as the physical port. The provider vSwitch strips the outer tag and forwards traffic to the appropriate customer. Then the customer switch strips the inner tag and forwards the packet to the appropriate customer VLAN.

To configure the interfaces:

1. Configure the interface to the provider that uses the outer tag:

```
config system interface
    edit "vlan-8021q"
        set vdom "root"
        set device-identification enable
        set role lan
        set interface "port5"
        set vlan-protocol 8021q
        set vlanid 100
    next
end
```

2. Configure the interface to the provider that uses the inner tag:

```
config system interface
    edit "vlan-qinq8021q"
        set vdom "root"
        set ip 1.1.1.71 255.255.255.0
        set allowaccess ping https ssh snmp http
        set device-identification enable
        set role lan
        set interface "vlan-8021q"
        set vlanid 200
    next
end
```

To verify the traffic:

1. From the FortiGate, ping 1.1.1.72:

```
# execute ping 1.1.1.72
PING 1.1.1.72 (1.1.1.72): 56 data bytes
64 bytes from 1.1.1.72: icmp_seq=0 ttl=255 time=0.2 ms
64 bytes from 1.1.1.72: icmp_seq=1 ttl=255 time=0.1 ms
64 bytes from 1.1.1.72: icmp_seq=2 ttl=255 time=0.1 ms
64 bytes from 1.1.1.72: icmp_seq=3 ttl=255 time=0.1 ms
^C
--- 1.1.1.72 ping statistics ---
4 packets transmitted, 4 packets received, 0% packet loss
round-trip min/avg/max = 0.1/0.1/0.2 ms
```

2. Verify the packet capture frame header output captured from the FortiGate's port5:

```
Frame 2: 106 bytes on wire (848 bits), 106 bytes captured (848 bits)
Ethernet II, Src: VMware_93:ae:8f (00:50:56:93:ae:8f), Dst: VMware_93:e3:72
(00:50:56:93:e3:72)
    Destination: VMware_93:e3:72 (00:50:56:93:e3:72)
    Source: VMware_93:ae:8f (00:50:56:93:ae:8f)
    Type: 802.1Q Virtual LAN (0x8100)
802.1Q Virtual LAN, PRI: 0, DEI: 0, ID: 100
    000. .... = Priority: Best Effort (default) (0)
    ...0 .... = DEI: Ineligible
    .... 0000 0110 0100 = ID: 100
    Type: 802.1Q Virtual LAN (0x8100)
802.1Q Virtual LAN, PRI: 0, DEI: 0, ID: 200
```

```
000. .... .... = Priority: Best Effort (default) (0)
...0 .... .... = DEI: Ineligible
.... 0000 1100 1000 = ID: 200
Type: IPv4 (0x0800)
Internet Protocol Version 4, Src: 1.1.1.71, Dst: 1.1.1.72
Internet Control Message Protocol
```

The outer tag (first tag) is an 802.1Q tag with VLAN ID 100. The inner tag (second tag) is also an 802.1Q tag with VLAN ID 200.

Aggregation and redundancy

Link aggregation (IEEE 802.3ad) enables you to bind two or more physical interfaces together to form an aggregated (combined) link. This new link has the bandwidth of all the links combined. If a link in the group fails, traffic is transferred automatically to the remaining interfaces. The only noticeable effect is reduced bandwidth.

This feature is similar to redundant interfaces. The major difference is a redundant interface group only uses one link at a time, where an aggregate link group uses the total bandwidth of the functioning links in the group, up to eight (or more).

An interface is available to be an aggregate interface if:

- It is a physical interface and not a VLAN interface or subinterface.
- It is not already part of an aggregate or redundant interface.
- It is in the same VDOM as the aggregated interface. Aggregate ports cannot span multiple VDOMs.
- It does not have an IP address and is not configured for DHCP or PPPoE.
- It is not referenced in any security policy, VIP, IP Pool, or multicast policy.
- It is not an HA heartbeat interface.
- It is not one of the FortiGate-5000 series backplane interfaces.

When an interface is included in an aggregate interface, it is not listed on the *Network > Interfaces* page. Interfaces still appear in the CLI although configuration for those interfaces do not take affect. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, IP pools, or routing.

Example configuration

This example creates an aggregate interface on a FortiGate-140D POE using ports 3-5 with an internal IP address of 10.1.1.123, as well as the administrative access to HTTPS and SSH.

To create an aggregate interface in the GUI:

1. Go to *Network > Interfaces* and select *Create New > Interface*.
2. Set *Name* to *aggregate*.
3. Set *Type* to *802.3ad Aggregate*.
4. Set *Interface members* to *port4*, *port5*, and *port6*.
5. Set *Addressing mode* to *Manual*.
6. Set *IP/Netmask* to *10.1.1.123/24*.
7. For *Administrative Access*, select *HTTPS* and *SSH*.
8. Click *OK*.

To create an aggregate interface in the CLI:

```
config system interface
    edit "aggregate"
        set vdom "root"
        set ip 10.1.1.123 255.255.255.0
        set allowaccess https ssh
        set type aggregate
        set member "port4" "port5" "port6"
        set snmp-index 45
    next
end
```

Redundancy

In a redundant interface, traffic only goes over one interface at any time. This differs from an aggregated interface where traffic goes over all interfaces for increased bandwidth. This difference means redundant interfaces can have more robust configurations with fewer possible points of failure. This is important in a fully-meshed HA configuration.

An interface is available to be in a redundant interface if:

- It is a physical interface and not a VLAN interface.
- It is not already part of an aggregated or redundant interface.
- It is in the same VDOM as the redundant interface.
- It does not have an IP address and is not configured for DHCP or PPPoE.
- It has no DHCP server or relay configured on it.
- It does not have any VLAN subinterfaces.
- It is not referenced in any security policy, VIP, or multicast policy.
- It is not monitored by HA.
- It is not one of the FortiGate-5000 series backplane interfaces.

When an interface is included in a redundant interface, it is not listed on the *Network > Interfaces* page. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, or routing.

Example configuration

To create a redundant interface in the GUI:

1. Go to *Network > Interfaces* and select *Create New > Interface*.
2. Set *Name* to *redundant*.
3. Set *Type* to *Redundant Interface*.
4. Set *Interface members* to *port4*, *port5*, and *port6*.
5. Set *Addressing mode* to *Manual*.
6. Set *IP/Netmask* to *10.13.101.100/24*.
7. For *Administrative Access*, select *HTTPS* and *SSH*.
8. Click *OK*.

To create a redundant interface in the CLI:

```
config system interface
    edit "redundant"
```

```

        set vdom "root"
        set ip 10.13.101.100 255.255.255.0
        set allowaccess https http
        set type redundant
        set member "port4" "port5" "port6"
        set snmp-index 9
    next
end

```

Enhanced hashing for LAG member selection

FortiGate models that have an internal switch that supports modifying the distribution algorithm can use enhanced hashing to help distribute traffic evenly, or load balance, across links on the Link Aggregation (LAG) interface.

The enhanced hashing algorithm is based on a 5-tuple of the IP protocol, source IP address, destination IP address, source port, and destination port.

Different computation methods allow for more variation in the load balancing distribution, in case one algorithm does not distribute traffic evenly between links across different XAUIs. The available methods are:

xor16	Use the XOR operator to make a 16 bit hash.
xor8	Use the XOR operator to make an 8 bit hash.
xor4	Use the XOR operator to make a 4 bit hash.
crc16	Use the CRC-16-CCITT polynomial to make a 16 bit hash.

The following NP6 non-service FortiGate models support this feature: 1500D, 1500DT, 3000D, 3100D, 3200D, 3700D, and 5001D.

To configure the enhanced hashing:

```

config system npu
    set lag-out-port-select {enable | disable}
    config sw-eh-hash
        set computation {xor4 | xor8 | xor16 | crc16}
        set ip-protocol {include | exclude}
        set source-ip-upper-16 {include | exclude}
        set source-ip-lower-16 {include | exclude}
        set destination-ip-upper-16 {include | exclude}
        set destination-ip-lower-16 {include | exclude}
        set source-port {include | exclude}
        set destination-port {include | exclude}
        set netmask-length {0 - 32}
    end
end

```

For example, to use XOR16 and include all of the fields in the 5-tuple to compute the link in the LAG interface that the packet is distributed to:

```

config system npu
    set lag-out-port-select enable

```

```

config sw-eh-hash
    set computation xor16
    set ip-protocol include
    set source-ip-upper-16 include
    set source-ip-lower-16 include
    set destination-ip-upper-16 include
    set destination-ip-lower-16 include
    set source-port include
    set destination-port include
    set netmask-length 32
end
end

```

LAG interface status signals to peer device

FortiGate can signal LAG (link aggregate group) interface status to the peer device. If the number of available links in the LAG on the FortiGate falls below the configured minimum number of links (`min-links`), the LAG interface goes down on both the FortiGate and the peer device.

When the minimum number of links is satisfied again, the LAG interface automatically resumes operation on both the FortiGate and the peer device. While the LAG interface is down, interface members are in the Link Aggregation Control Protocol (LACP) MUX state of *Waiting*.

Example

In this example, the LAG interface is configured on FGT_A and peered with FGT_B.

To verify the configuration:

1. On FGT_A, check the minimum number of links for the LAG interface named `test_agg1`.

In the following example, `set min-links 1` indicates that a minimum of one alive interface member is required to keep the LAG interface up.

```

# show
config system interface
    edit "test_agg1"
        set vdom "vdom1"
        set ip 11.1.1.1 255.255.255.0
        set allowaccess ping https
        set type aggregate
        set member "port7" "port8" "port9"
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 41
        set min-links 1
    next
end

```

2. Change the status of port9 to down.

```

Config system interface
    edit port9

```

```

    set status down
end

```

3. On FGT_A, test the LAG interface named test_agg1.

The status is up for test_agg1 interface because two interface members (port7 and port8) are up, and only one interface member (port9) is down.

```

# diagnose netlink aggregate name test_agg1
LACP flags: (A|P) (S|F) (A|I) (I|O) (E|D) (E|D)
(A|P) - LACP mode is Active or Passive
(S|F) - LACP speed is Slow or Fast
(A|I) - Aggregatable or Individual
(I|O) - Port In sync or Out of sync
(E|D) - Frame collection is Enabled or Disabled
(E|D) - Frame distribution is Enabled or Disabled

```

status: up

```

```

4. On FGT_A, change the minimum number of links to 3.

```

config system interface
  edit "test_agg1"
    set vdom "vdom1"
    set ip 11.1.1.1 255.255.255.0
    set allowaccess ping https
    set type aggregate
    set member "port7" "port8" "port9"
    set device-identification enable
    set lldp-transmission enable
    set role lan
    set snmp-index 41
    set min-links 3
  next
end

```

5. On FGT_A, check the LAG interface named test_agg1:

The status is down for test_agg1 interface because only two of the three required interface members are up. Interface members port7 and port8 are up, but interface member port9 is down.

```

# diagnose netlink aggregate name agg1
LACP flags: (A|P) (S|F) (A|I) (I|O) (E|D) (E|D)
(A|P) - LACP mode is Active or Passive

```

Failure detection for aggregate and redundant interfaces

When an aggregate or redundant interface goes down, the corresponding fail-alert interface changes to down. When an aggregate or redundant interface comes up, the corresponding fail-alert interface changes to up.

Fail-detect for aggregate and redundant interfaces can be configured using the CLI.

To configure an aggregate interface so that port3 goes down with it:

```

config system interface
  edit "aggl"
    set vdom "root"
    set fail-detect enable
    set fail-alert-method link-down
    set fail-alert-interfaces "port3"
    set type aggregate
    set member "port1" "port2"
  next
end

```

To configure a redundant interface so that port4 goes down with it:

```

config system interface
  edit "red1"
    set vdom "root"
    set fail-detect enable
    set fail-alert-method link-down
    set fail-alert-interfaces "port4"
    set type redundant
    set member "port1" "port2"
  next
end

```

Loopback interface

A loopback interface is a logical interface that is always up. Its IP address does not depend on one specific physical port, and the attached subnet is always present in the routing table. Therefore, it can be accessed through several physical or VLAN interfaces.

Typically, a loopback interface can be used with management access, BGP peering, PIM rendezvous points, and SD-WAN.

Loopback interfaces require appropriate firewall policies to allow traffic to and from the interfaces. Multiple loopback interfaces can be configured in either non-VDOM mode or in each VDOM.

Dynamic routing protocols can be enabled on loopback interfaces. For example, loopback interfaces are a good practice for OSPF. To make it easier to troubleshoot OSPF, set the OSPF router ID to the same value as the loopback IP address to access a specific FortiGate using that IP address and SSH.

A loopback interface is configured using similar steps as a physical interface (see [Configuring an interface](#)).

Software switch

A software switch is a virtual switch that is implemented at the software or firmware level and not at the hardware level. A software switch can be used to simplify communication between devices connected to different FortiGate interfaces. For example, a software switch lets you place the FortiGate interface connected to an internal network on the same subnet as your wireless interfaces. Then devices on the internal network can communicate with devices on the wireless network without any additional configuration on the FortiGate unit, such as additional security policies.

A software switch can also be useful if you require more hardware ports for the switch on a FortiGate unit. For example, if your FortiGate unit has a 4-port switch, WAN1, WAN2, and DMZ interfaces, and you need one more port, you can create a soft switch that can include the four-port switch and the DMZ interface, all on the same subnet. These types of applications also apply to wireless interfaces, virtual wireless interfaces, and physical interfaces such as those in FortiWiFi and FortiAP units.

Similar to a hardware switch, a software switch functions like a single interface. It has one IP address, and all the interfaces in the software switch are on the same subnet. Traffic between devices connected to each interface is not regulated by security policies, and traffic passing in and out of the switch is controlled by the same policy.

When setting up a software switch, consider the following:

- Ensure that you have a back up of the configuration.
- Ensure that you have at least one port or connection, such as the console port, to connect to the FortiGate unit. If you accidentally combine too many ports, you need a way to undo errors.
- The ports that you include must not have any link or relation to any other aspect of the FortiGate unit, such as DHCP servers, security policies, and so on.
- Ensure the *Create address object matching subnet* option is disabled, if any port *Role* is set to either *LAN* or *DMZ*.
- For increased security, you can create a captive portal for the switch to allow only specific user groups access to the resources connected to the switch.

Some of the difference between software and hardware switches are:

Feature	Software switch	Hardware switch
Processing	Packets are processed in software by the CPU.	Packets are processed in hardware by the hardware switch controller, or SPU where applicable.
STP	Not Supported	Supported
Wireless SSIDs	Supported	Not Supported
Intra-switch traffic	Allowed by default. Can be explicitly set to require a policy.	Allowed by default.

To create a software switch in the GUI:

1. Go to *Network > Interfaces*.
2. Click *Create New > Interface*.
3. Set *Type* to *Software Switch*.
4. Configure the *Name*, *Interface members*, and other fields as required.
To add an interface to a software switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.
5. Click *OK*.

To create a software switch in the CLI:

```
config system switch-interface
    edit <interface>
        set vdom <vdom>
        set member <interface_list>
        set type switch
    next
end
config system interface
    edit <interface>
        set vdom <vdom>
        set type switch
        set ip <ip_address>
        set allowaccess https ssh ping
    next
end
```

To add an interface to a software switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.

Example

For this example, the wireless interface (WiFi) needs to be on the same subnet as the DMZ1 interface to facilitate wireless synchronization between an iPhone and a local computer. Because synchronization between two subnets is problematic, putting both interfaces on the same subnet allows synchronization to work. The software switch will accomplish this.

1. Clear the interfaces and back up the configuration:
 - a. Ensure the interfaces are not used for other security policy or for other use on the FortiGate unit.
 - b. Check the WiFi and DMZ1 ports to ensure that DHCP is disabled and that there are no other dependencies on these interfaces.
 - c. Save the current configuration so that it can be recovered if something goes wrong.
2. Merge the WiFi port and DMZ1 port to create a software switch named `synchro` with an IP address of 10.10.21.12 and administrative access for HTTPS, SSH and PING:

```
config system switch-interface
    edit synchro
        set vdom "root"
        set type switch
        set member dmz1 wifi
    next
```

```

end
config system interface
    edit synchro
        set ip 10.10.21.12 255.255.255.0
        set allowaccess https ssh ping
    next
end

```

After the switch is set up, add security policies, DHCP servers, and any other settings that are required.

Hardware switch

A hardware switch is a virtual switch interface that groups different ports together so that the FortiGate can use the group as a single interface. Supported FortiGate models have a default hardware switch called either *internal* or *lan*. The hardware switch is supported by the chipset at the hardware level.

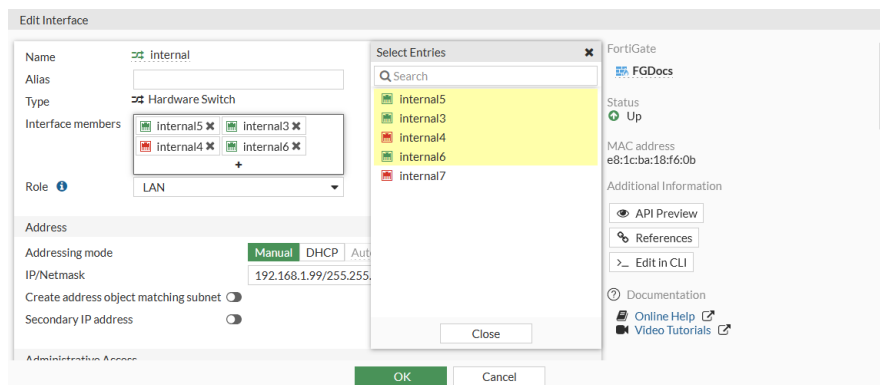

Ports that are connected to the same hardware switch behave like they are on the same physical switch in the same broadcast domain. Ports can be removed from a hardware switch and assigned to another switch or used as standalone interfaces.

Some of the difference between hardware and software switches are:

Feature	Hardware switch	Software switch
Processing	Packets are processed in hardware by the hardware switch controller, or SPU where applicable.	Packets are processed in software by the CPU.
STP	Supported	Not Supported
Wireless SSIDs	Not Supported	Supported
Intra-switch traffic	Allowed by default.	Allowed by default. Can be explicitly set to require a policy.

To change the ports in a hardware switch in the GUI:

1. Go to *Network > Interface* and edit the hardware switch.
2. Click inside the *Interface members* field.

3. Select interfaces to add or remove them from the hardware switch, then click *Close*.
To add an interface to a hardware switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.
4. Click *OK*.
Removed interfaces will now be listed as standalone interfaces in the *Physical Interface* section.

To remove ports from a hardware switch in the CLI:

```
config system virtual-switch
  edit "internal"
    config port
      delete internal2
      delete internal7
      ...
    end
  next
end
```

To add ports to a hardware switch in the CLI:

```
config system virtual-switch
  edit "internal"
    set physical-switch "sw0"
    config port
      edit "internal3"
      next
      edit "internal5"
      next
      edit "internal4"
      next
      edit "internal6"
      next
    end
  next
end
```

To add an interface to a hardware switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.

Using 802.1X on virtual switches for certain NP6 platforms

802.1X is supported under the hardware switch interface on the following NP6 platforms: FG-30xE, FG-40xE, and FG-110xE.

In this example, port3 and port4 are part of a hardware switch interface. The hardware switch acts as a virtual switch so that devices can connect directly to these ports and perform 802.1X authentication on the port.

Prerequisites:

1. Configure a RADIUS server (see [RADIUS servers on page 2258](#)).
2. Define a user group named test to use the remote RADIUS server and for 802.1X authentication (see [User definition and groups on page 2229](#)).
3. Configure a hardware switch (named 18188) with port3 and port4 as the members.
4. Configure a firewall policy that allows traffic from the 18188 hardware switch to go to the internet.
5. Enable 802.1X authentication on the client devices.

To configure 802.1X authentication on a hardware switch in the GUI:

1. Go to *Network > Interfaces* and edit the hardware switch.
2. In the *Network* section, enable *Security mode* and select *802.1X*.

3. Click the + to add the *User group*.

4. Click OK.

To configure 802.1X authentication on a hardware switch in the CLI:

1. Configure the virtual hardware switch interfaces:

```
config system virtual-switch
  edit "18188"
    set physical-switch "sw0"
  config port
    edit "port3"
    next
    edit "port4"
    next
  end
end
```

```

        end
    next
end

```

2. Configure 802.1X authentication:

```

config system interface
    edit "18188"
        set vdom "vdom1"
        set ip 1.1.1.1 255.255.255.0
        set allowaccess ping https ssh snmp fgfm ftm
        set type hard-switch
        set security-mode 802.1X
        set security-groups "test"
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 52
    next
end

```

To verify the that the 802.1X authentication was successful:

1. Get a client connected to port3 to authenticate to access the internet.
2. In FortiOS, verify the 802.1X authentication port status:

```

# diagnose sys 802-1x status

Virtual switch '18188' (default mode) 802.1x member status:
    port3: Link up, 802.1X state: authorized
    port4: Link up, 802.1X state: unauthorized

```

Zone

Zones are a group of one or more physical or virtual FortiGate interfaces that you can apply firewall policies to for controlling inbound and outbound traffic. Grouping interfaces and VLAN subinterfaces into zones simplifies creating firewall policies where a number of network segments can use the same policy settings and protection profiles.

When you add a zone, you select the names of the interfaces and VLAN subinterfaces to add to the zone. Each interface still has its own address. Routing is still done between interfaces, that is, routing is not affected by zones. You can use firewall policies to control the flow of intra-zone traffic.

For example, in the sample configuration below, the network includes three separate groups of users representing different entities on the company network. While each group has its own set of ports and VLANs in each area, they can all use the same firewall policy and protection profiles to access the Internet. Rather than the administrator making nine separate firewall policies, he can make administration simpler by adding the required interfaces to a zone and creating three policies.

Example configuration

You can configure policies for connections to and from a zone but not between interfaces in a zone. For this example, you can create a firewall policy to go between zone 1 and zone 3, but not between WAN2 and WAN1, or WAN1 and DMZ1.

To create a zone in the GUI:

1. Go to *Network > Interfaces*.

If VDOMs are enabled, go to the VDOM to create a zone.

2. Click *Create New > Zone*.
3. Configure the *Name* and add the *Interface Members*.
4. Enable or disable *Block intra-zone traffic* as required.
5. Click *OK*.

To configure a zone to include the internal interface and a VLAN using the CLI:

```

config system zone
    edit zone_1
        set interface internal VLAN_1
        set intrazone {deny | allow}
    next
end
  
```

Using zone in a firewall policy

To configure a firewall policy to allow any interface to access the Internet using the CLI:

```

config firewall policy
    edit 2
        set name "2"
        set srcintf "Zone_1"
        set dstintf "port15"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
  
```

Intra-zone traffic

In the zone configuration you can set `intrazone deny` to prohibit the different interfaces in the same zone to talk to each other.

For example, if you have ten interfaces in your zone and the `intrazone` setting is `deny`. You now want to allow traffic between a very small number of networks on different interfaces that are part of the zone but you do not want to disable the intra-zone blocking.

In this example, the zone VLANs are defined as: `192.168.1.0/24`, `192.168.2.0/24`, ... `192.168.10.0/24`.

This policy allows traffic from `192.168.1.x` to `192.168.2.x` even though they are in the same zone and intra-zone blocking is enabled. The intra-zone blocking acts as a default deny rule and you have to specifically override it by creating a policy within the zone.

To enable intra-zone traffic, create the following policy:

Source Interface	Zone-name, e.g., <code>Vlans</code>
Source Address	<code>192.168.1.0/24</code>
Destination	Zone-name (same as Source Interface, i.e., <code>Vlans</code>)
Destination Address	<code>192.168.2.0/24</code>

Virtual wire pair

A virtual wire pair consists of two interfaces that do not have IP addressing and are treated like a transparent mode VDOM. All traffic received by one interface in the virtual wire pair can only be forwarded to the other interface, provided a virtual wire pair firewall policy allows this traffic. Traffic from other interfaces cannot be routed to the interfaces in a virtual wire pair. Redundant and 802.3ad aggregate (LACP) interfaces can be included in a virtual wire pair.

Virtual wire pairs are useful for a typical topology where MAC addresses do not behave normally. For example, port pairing can be used in a Direct Server Return (DSR) topology where the response MAC address pair may not match the request's MAC address pair.

Example

In this example, a virtual wire pair (port3 and port4) makes it easier to protect a web server that is behind a FortiGate operating as an Internal Segmentation Firewall (ISFW). Users on the internal network access the web server through the ISFW over the virtual wire pair.

Interfaces used in a virtual wire pair cannot be used to access the ISFW FortiGate. Before creating a virtual wire pair, make sure you have a different port configured to allow admin access using your preferred protocol.

To add a virtual wire pair using the GUI:

1. Go to *Network > Interfaces*.
2. Click *Create New > Virtual Wire Pair*.
3. Enter a name for the virtual wire pair.
4. Select the *Interface Members* to add to the virtual wire pair (*port3* and *port4*).
These interfaces cannot be part of a switch, such as the default LAN/internal interface.
5. If required, enable *Wildcard VLAN* and set the *VLAN Filter*.
6. Click *OK*.

To add a virtual wire pair using the CLI:

```
config system virtual-wire-pair
  edit "VWP-name"
    set member "port3" "port4"
    set wildcard-vlan disable
  next
end
```

To create a virtual wire pair policy using the GUI:

1. Go to *Policy & Objects > Firewall Virtual Wire Pair Policy*.
2. Click *Create New*.
3. In the *Virtual Wire Pair* field, click the + to add the virtual wire pair.
4. Select the direction (arrows) that traffic is allowed to flow.
5. Configure the other settings as needed.
6. Click *OK*.

To create a virtual wire pair policy using the CLI:

```
config firewall policy
  edit 1
    set name "VWP-Policy"
    set srcintf "port3" "port4"
    set dstintf "port3" "port4"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set fsso disable
```

```
next
end
```

Configuring multiple virtual wire pairs in a virtual wire pair policy

You can create a virtual wire pair policy that includes different virtual wire pairs in NGFW profile and policy mode. This reduces overhead to create multiple similar policies for each VWP. In NGFW policy mode, multiple virtual wire pairs can be configured in a *Security Virtual Wire Pair Policy* and *Virtual Wire Pair SSL Inspection & Authentication* policy.

The virtual wire pair settings must have wildcard VLAN enabled. When configuring a policy in the CLI, the virtual wire pair members must be entered in `srcintf` and `dstintf` as pairs.

To configure multiple virtual wire pairs in a policy in the GUI:

1. Configure the virtual wire pairs:

- a. Go to *Network > Interfaces* and click *Create New > Virtual Wire Pair*.
- b. Create a pair with the following settings:

Name	test-vwp-1
Interface members	wan1, wan2
Wildcard VLAN	Enable

- c. Click *OK*.
- d. Click *Create New > Virtual Wire Pair* and create another pair with the following settings:

Name	test-vwp-2
Interface members	port19, port20
Wildcard VLAN	Enable

- e. Click *OK*.
2. Configure the policy:
- a. Go to *Policy & Objects > Firewall Virtual Wire Pair Policy* and click *Create New*.
 - b. In the *Virtual Wire Pair* field, click the + to add *test-vwp-1* and *test-vwp-2*. Select the direction for each of the selected virtual wire pairs.

- c. Configure the other settings as needed.
- d. Click OK.

To configure multiple virtual wire pairs in a policy in the CLI:

1. Configure the virtual wire pairs:

```
config system virtual-wire-pair
  edit "test-vwp-1"
    set member "wan1" "wan2"
    set wildcard-vlan enable
  next
  edit "test-vwp-2"
    set member "port19" "port20"
    set wildcard-vlan enable
  next
end
```

2. Configure the policy:

```
config firewall policy
  edit 1
    set name "vwp1&2-policy"
    set srcintf "port19" "wan1"
    set dstintf "port20" "wan2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
  next
end
```

PRP handling in NAT mode with virtual wire pair

PRP (Parallel Redundancy Protocol) is supported in NAT mode for a virtual wire pair. This preserves the PRP RCT (redundancy control trailer) while the packet is processed by the FortiGate.

To configure PRP handling on a device in NAT mode:

1. Enable PRP in the VDOM settings:

```
(root) # config system settings
      set prp-trailer-action enable
end
```

2. Enable PRP in the NPU attributes:

```
(global) # config system npu
      set prp-port-in "port15"
      set prp-port-out "port16"
end
```

3. Configure the virtual wire pair:

```
(root) # config system virtual-wire-pair
      edit "test-vwp-1"
        set member "port15" "port16"
      next
end
```

Using VLAN sub-interfaces in virtual wire pairs

VLAN sub-interfaces, such as regular 802.1Q and 802.1ad (QinQ), are allowed to be members of a virtual wire pair.

Example

In this example, the FortiGate has two VLAN interfaces. The first interface is a QinQ (802.1ad) interface over the physical interface port3. The second interface is a basic 802.1Q VLAN interface over physical interface port5. These two interfaces are grouped in a virtual wire pair so that bi-directional traffic is allowed. This example demonstrates ICMP from the client (3.3.3.4) sent to the server (3.3.3.1).

To configure VLAN sub-interfaces in a virtual wire pair:**1. Configure the QinQ interfaces:**

```
config system interface
    edit "8021ad-port3"
        set vdom "vdom1"
        set vlan-protocol 8021ad
        set device-identification enable
        set role lan
        set snmp-index 31
        set interface "port3"
        set vlanid 3
    next
    edit "8021Q"
        set vdom "vdom1"
        set device-identification enable
        set role lan
        set snmp-index 32
        set interface "8021ad-port3"
        set vlanid 33
    next
end
```

2. Configure the 802.1Q interface:

```
config system interface
    edit "8021q-port5"
        set vdom "vdom1"
        set device-identification enable
        set role lan
        set snmp-index 33
        set interface "port5"
        set vlanid 5
    next
end
```

3. Configure the virtual wire pair:

```
config system virtual-wire-pair
    edit "VWP1"
        set member "8021Q" "8021q-port5"
    next
end
```

4. Configure the firewall policy:

```
config firewall policy
    edit 1
        set name "1"
        set srcintf "8021Q" "8021q-port5"
        set dstintf "8021Q" "8021q-port5"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
```

```

    next
end

```

To verify that bi-directional traffic passes through the FortiGate:

```

# diagnose sys session filter policy 1
# diagnose sys session list

session info: proto=1 proto_state=00 duration=18 expire=42 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3

total session 1

```

DVLAN QinQ on NP7 platforms

DVLAN 802.1ad and 802.1Q modes are supported on NP7 platforms, which provides better performance and packet processing.

The default DVLAN mode is 802.1ad, but the DVLAN mode can be changed using `diagnose npu np7 dvlan-mode <dvlan_mode> {<npid> | all}`. The DVLAN mode can be applied to a specific NPID or all NPIDs. For example:

- `diagnose npu np7 dvlan-mode 802.1AD 0` will set NP0 to work in 802.1ad mode.
- `diagnose npu np7 dvlan-mode 802.1Q all` will set all NPUs to work in 802.1Q mode.

A reboot is required for custom DVLAN settings to take effect. To avoid any inconveniences or disruptions, changing the DVLAN settings should be done during a scheduled downtime or maintenance window.

In the virtual wire pair settings, the `outer-vlan-id` can be set. This is the same value as the outer provider-tag (S-Tag).

To configure the outer VLAN ID:

```

config system virtual-wire-pair
    edit "dvlan-test"
        set member "port33" "port34"
        set wildcard-vlan enable

```

```
set outer-vlan-id 1234
next
end
```

Enhanced MAC VLAN

The Media Access Control (MAC) Virtual Local Area Network (VLAN) feature in Linux allows you to configure multiple virtual interfaces with different MAC addresses (and therefore different IP addresses) on a physical interface.

FortiGate implements an enhanced MAC VLAN consisting of a MAC VLAN with bridge functionality. Because each MAC VLAN has a unique MAC address, virtual IP addresses (VIPs) and IP pools are supported, and you can disable Source Network Address Translation (SNAT) in policies.

MAC VLAN cannot be used in a transparent mode virtual domain (VDM). In a transparent mode VDM, a packet leaves an interface with the MAC address of the original source instead of the interface's MAC address. FortiGate implements an enhanced version of MAC VLAN where it adds a MAC table in the MAC VLAN which learns the MAC addresses when traffic passes through.

If you configure a VLAN ID for an enhanced MAC VLAN, it won't join the switch of the underlying interface. When a packet is sent to this interface, a VLAN tag is inserted in the packet and the packet is sent to the driver of the underlying interface. When the underlying interface receives a packet, if the VLAN ID doesn't match, it won't deliver the packet to this enhanced MAC VLAN interface.

When using a VLAN ID, the ID and the underlying interface must be a unique pair, even if they belong to different VDMs. This is because the underlying, physical interface uses the VLAN ID as the identifier to dispatch traffic among the VLAN and enhanced MAC VLAN interfaces.

If you use an interface in an enhanced MAC VLAN, do not use it for other purposes such as a management interface, HA heartbeat interface, or in Transparent VDMs.

If a physical interface is used by an EMAC VLAN interface, you cannot use it in a Virtual Wire Pair.

In high availability (HA) configurations, enhanced MAC VLAN is treated as a physical interface. It's assigned a unique physical interface ID and the MAC table is synchronized with the secondary devices in the same HA cluster.

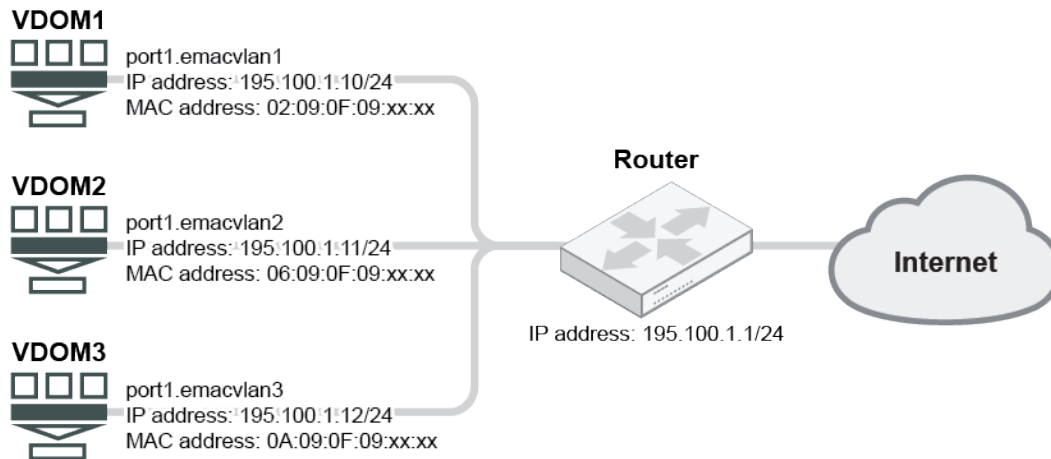

In HA configurations, FortiGate assigns a virtual MAC to each interface. Virtual interfaces, such as EMAC VLAN interfaces with underlying NPU VLINK interface, are an exception and do not get assigned virtual MAC addresses.

Example 1: Enhanced MAC VLAN configuration for multiple VDMs that use the same interface or VLAN

In this example, a FortiGate is connected, through port 1 to a router that's connected to the Internet. Three VDMs share the same interface (port 1) which connects to the same router that's connected to the Internet. Three enhanced MAC VLAN interfaces are configured on port 1 for the three VDMs. The enhanced MAC VLAN interfaces are in the same IP subnet segment and each have unique MAC addresses.

The underlying interface (port 1) can be a physical interface, an aggregate interface, or a VLAN interface on a physical or aggregate interface.

To configure enhanced MAC VLAN for this example in the CLI:

```

config system interface
    edit port1.emacvlan1
        set vdom VDOM1
        set type emac-vlan
        set interface port1
    next
    edit port 1.emacvlan2
        set vdom VDOM2
        set type emac-vlan
        set interface port1
    next
    edit port1.emacvlan3
        set vdom VDOM3
        set type emac-vlan
        set interface port1
    next
end
  
```

Example 2: Enhanced MAC VLAN configuration for shared VDOM links among multiple VDOMs

In this example, multiple VDOMs can connect to each other using enhanced MAC VLAN on network processing unit (NPU) virtual link (Vlink) interfaces.

FortiGate VDOM links (NPU-Vlink) are designed to be peer-to-peer connections and VLAN interfaces on NPU Vlink ports use the same MAC address. Connecting more than two VDOMs using NPU Vlinks and VLAN interfaces is not recommended as the VLAN interfaces share the same MAC address. To avoid overlapping MAC addresses on the same NPU Vlink, use EMAC VLANs instead.

To configure enhanced MAC VLAN for this example in the CLI:

```
config system interface
  edit npu0_vlink0.emacvlan1
    set vdom VDOM1
    set type emac-vlan
    set interface npu0_vlink0
  next
  edit npu0_vlink0.emacvlan2
    set vdom VDOM3
    set type emac-vlan
    set interface npu0_vlink0
  next
  edit npu0_vlink1.emacvlan1
    set vdom VDOM2
    set type emac-vlan
    set interface npu0_vlink1
  next
end
```

Example 3: Enhanced MAC VLAN configuration for unique MAC addresses for each VLAN interface on the same physical port

Some networks require a unique MAC address for each VLAN interface when the VLAN interfaces share the same physical port. In this case, the enhanced MAC VLAN interface is used the same way as normal VLAN interfaces.

To configure this, use the `set vlandid` command for the VLAN tag. The VLAN ID and interface must be a unique pair, even if they belong to different VDOMs.

To configure enhanced MAC VLAN:

```
config system interface
  edit <interface-name>
    set type emac-vlan
    set vlandid <VLAN-ID>
    set interface <physical-interface>
  next
end
```

FortiGate supports a maximum of 512 EMAC VLAN interfaces per underlying interface, and a maximum of 600 MAC addresses including EMAC VLAN interfaces.

VXLAN

Virtual Extensible LAN (VXLAN) is a network virtualization technology used in large cloud computing deployments. It encapsulates layer 2 Ethernet frames within layer 3 IP packets using the UDP transport protocol on port 4789. VXLAN endpoints that terminate VXLAN tunnels can be virtual or physical switch ports, and are known as VXLAN tunnel endpoints (VTEPs).

Sample VXLAN packet

A VXLAN packet encapsulation occurs by first inserting a VXLAN header in front of the original layer 2 frame. This VXLAN header uses 3 B for the VNID that is used to identify the VXLAN segment, meaning that there are 16,777,215 different possible VNIDs. This allows for more unique LAN segments than possible VLANs. The original frame and the VXLAN header are then encapsulated into the UDP payload. The outer IP header allows it to be routed and transported over a layer 3 network, thus providing a layer 2 overlay scheme over a layer 3 network.

This equates to 50 B of overhead over the original frame: 14 B (Ethernet) + 20 B (IPv4) + 8 B (UDP) + 8 B (VXLAN headers). Since fragmenting a VXLAN packet is not recommended, it is advisable to increase the MTU size to 1550 B or above if possible, or to decrease the TCP MSS size inside a firewall policy.

For more information about VXLAN, see [RFC 7348](#).

The following topics provide information about VXLAN:

- [General VXLAN configuration and topologies on page 232](#)
- [VLAN inside VXLAN on page 237](#)
- [Virtual wire pair with VXLAN on page 239](#)
- [VXLAN over IPsec tunnel with virtual wire pair on page 241](#)
- [VXLAN over IPsec using a VXLAN tunnel endpoint on page 245](#)
- [VXLAN with MP-BGP EVPN on page 250](#)
- [VXLAN troubleshooting on page 263](#)

General VXLAN configuration and topologies

This topic describes general VXLAN configurations and commonly used topologies. In the most basic configuration, a FortiGate is configured as a VXLAN tunnel endpoint (VTEP).

To configure a FortiGate as a VTEP:

1. Configure the local interface:

```
config system vxlan
    edit <name>
        set interface <string>
        set vni <integer>
        set ip-version {ipv4-unicast | ipv6-unicast | ipv4-multicast | ipv6-multicast}
        set dstport <integer>
        set remote-ip <IP_address>
        set remote-ip6 <IP_address>
    next
end
```

interface <string>	Set the local outgoing interface for the VXLAN encapsulated traffic.
vni <integer>	Set the VXLAN network ID.
ip-version {ipv4-unicast ipv6-unicast ipv4-multicast ipv6-multicast}	Set the IP version to use for the VXLAN device and communication over VXLAN (default = ipv4-unicast).
dstport <integer>	Set the VXLAN destination port (default = 4789).
remote-ip <IP_address>	Set the IPv4 address of the remote VXLAN endpoint.
remote-ip6 <IP_address>	Set the IPv6 address of the remote VXLAN endpoint.

The VXLAN system interface is automatically created with a `vxlan` type.

2. Configure the VXLAN interface settings:

```
config system interface
    edit <name>
        set vdom <string>
        set type vxlan
        set ip <IP_address>
        set allowaccess {ping https ssh http telnet fgfm radius-acct probe-response
fabric ftm speed-test}
    next
end
```

3. Connect the internal interface and VXLAN interface to the same L2 network.

- Connect using a software switch:

```
config system switch-interface
    edit <name>
        set vdom <string>
        set member <member_1> <member_2> ... <member_n>
        set intra-switch-policy {implicit | explicit}
    next
end
```

member <member_1> <member_2> ... <member_n>	Enter the VXLAN interface and other physical or virtual interfaces that will share the L2 network.
---	--

When adding an interface member to a software switch, it cannot have an IP address or be referenced in any other settings. For newly created VLAN interfaces, it is advised to change the role from LAN to undefined so that an address is not automatically assigned.

```
intra-switch-policy
{implicit |
explicit}
```

Allow any traffic between switch interfaces or require firewall policies to allow traffic between switch interfaces:

- implicit: traffic between switch members is implicitly allowed.
- explicit: traffic between switch members must match firewall policies (explicit firewall policies are required to allow traffic between members).

- Connect using a virtual wire pair:

```
config system virtual-wire-pair
edit <name>
set member <member_1> <member_2>
set wildcard-vlan {enable | disable}
set vlan-filter <filter>
next
end
```

```
member <member_1>
<member_2>
```

Enter the VXLAN interface and other physical or virtual interface that will share the L2 network.

```
wildcard-vlan {enable |
disable}
```

Enable/disable wildcard VLAN. Disable to prevent VLAN-tagged traffic between the members of the virtual wire pair (default). Enable for VLAN tags to be allowed between the members.

```
vlan-filter <filter>
```

When wildcard-vlan is enabled, set the VLAN filter to specify which VLANs are allowed. By default, an empty vlan-filter allows all VLANs.

4. If using a virtual wire pair, configure a firewall policy that allows bi-directional traffic between the members of the virtual wire pair and inspection between them:

```
config firewall policy
edit <id>
set name <name>
set srcintf <member_1> <member_2>
set dstintf <member_1> <member_2>
set srcaddr "all"
set dstaddr "all"
set action accept
set schedule "always"
set service "ALL"
next
end
```

Topologies

Many topologies can be deployed with VXLAN. A FortiGate can connect to VXLAN endpoints that are Fortinet devices or devices from other vendors. In the following topologies, it is assumed that at least one of the VTEPs is a FortiGate. The second VTEP can be any vendor.

Basic VXLAN between two VTEPs

In this topology, a FortiGate (VTEP 1) is configured with a VXLAN interface over port1 where the `remote-ip` points to port1 of VTEP 2. The VXLAN interface and port2 can be associated with the same L2 network by making them members of either a software switch or a virtual wire pair. Devices under the L2 switches are part of the same L2 network.

See [Virtual wire pair with VXLAN on page 239](#) for an example configuration.

VXLAN between two VTEPs with wildcard VLANs

In this topology, a FortiGate (VTEP 1) is configured with a VXLAN interface over port1 where the `remote-ip` points to port1 of VTEP 2. The VXLAN interface is combined with port2 into the same L2 network using a virtual wire pair. The virtual wire pair allows wildcard VLANs to pass, which allows VLAN tags to be encapsulated over VXLAN. As a result, VLANs can span different switches over VXLAN.

Variations of these two scenarios can also be found in FortiGate to FortiSwitch FortiLink connections over VXLAN. See [Deployment procedures](#) in the FortiSwitch VXLAN Deployment Guide for example configurations.

VXLAN between two VTEPs over IPsec

In scenarios where VTEPs are located in different sites and traffic must be secured between the sites, VXLAN will need to be encrypted over IPsec. The VXLAN interface must use the IPsec interface as its outgoing interface. The `remote-ip` must be configured as the IP of the remote IPsec gateway. The VXLAN interface can be combined with `port2` into the same L2 network using a software switch or virtual wire pair. Devices under the L2 switches can communicate with each other.

See [VXLAN over IPsec tunnel with virtual wire pair on page 241](#) for an example configuration. A variation of this scenario is explained in [FortiGate LAN extension on page 684](#) and in [FortiExtender as FortiGate LAN extension](#) (FortiExtender FortiGate-Managed Administration Guide).

VXLAN between multiple VTEPs in an IPsec hub and spoke topology

In this topology, an IPsec VPN hub and spoke overlay network is already configured between sites. To allow networks behind the hub and spokes to be connected together, each spoke has a VXLAN connection to the hub, and the hub allows interconnection between its private network and each of the VXLAN interfaces to the spokes. In this scenario, the private networks behind each spoke are actually on the same L2 network as the private network behind the hub.

See [VXLAN over IPsec using a VXLAN tunnel endpoint on page 245](#) for an example configuration.

VLAN inside VXLAN

VLANs can be assigned to VXLAN interfaces. In a data center network where VXLAN is used to create an L2 overlay network and for multitenant environments, a customer VLAN tag can be assigned to VXLAN interface. This allows the VLAN tag from VLAN traffic to be encapsulated within the VXLAN packet.

To configure VLAN inside VXLAN on HQ1:**1. Configure VXLAN:**

```
config system vxlan
  edit "vxlan1"
    set interface port1
    set vni 1000
    set remote-ip 173.1.1.1
  next
end
```

2. Configure system interface:

```
config system interface
  edit vlan100
    set vdom root
    set vlanid 100
    set interface dmz
  next
  edit vxlan100
    set type vlan
    set vlanid 100
    set vdom root
    set interface vxlan1
  next
end
```

3. Configure software-switch:

```
config system switch-interface
  edit sw1
    set vdom root
    set member vlan100 vxlan100
    set intra-switch-policy implicit
  next
end
```

The default `intra-switch-policy implicit` behavior allows traffic between member interfaces within the switch. Therefore, it is not necessary to create firewall policies to allow this traffic.

Instead of creating a software-switch, it is possible to use a virtual-wire-pair as well. See [Virtual wire pair with VXLAN on page 239](#).

To configure VLAN inside VXLAN on HQ2:**1. Configure VXLAN:**

```
config system vxlan
  edit "vxlan2"
    set interface port25
    set vni 1000
    set remote-ip 173.1.1.2
  next
```

```
end
```

2. Configure system interface:

```
config system interface
edit vlan100
set vdom root
set vlanid 100
set interface port20
next
edit vxlan100
set type vlan
set vlanid 100
set vdom root
set interface vxlan2
next
end
```

3. Configure software-switch:

```
config system switch-interface
edit sw1
set vdom root
set member vlan100 vxlan100
next
end
```

To verify the configuration:

Ping PC1 from PC2.

The following is captured on HQ2:

The image shows a Wireshark packet capture on interface eth0. The filter is 'eth0'. The capture shows several ICMP Echo (ping) requests and replies between 20.1.1.1 and 20.1.1.2. The packets are tagged with VLAN 100. The packet details pane shows the following structure:

- Frame 3: 152 bytes on wire (1216 bits), 152 bytes captured (1216 bits) on interface eth0
- Ethernet II, Src: Fortinet-5b:a6:eb (08:5b:0e:eb:c8:99), Dst: Fortinet-32:1a:d6 (90:6c:ac:32:1a:d6)
- Internet Protocol Version 4, Src: 173.1.1.1, Dst: 173.1.1.2
- User Datagram Protocol, Src Port: 4829, Dst Port: 4789
- Virtual extensible local Area Network
- Ethernet II, Src: Fortinet-5b:a6:eb (90:6c:ac:5b:a6:eb), Dst: Fortinet-dd:69:cc (08:5b:0e:dd:69:cc)
- 802.1Q (Virtual LAN, PVID: 0, DEI: 0, ID: 100)
 - 0000 = Priority: Best effort (default) (0)
 - = DEI: Ineligible
 - 0000 0100 = ID: 100
 - Type: IPv4 (0x0008)
- Internet Protocol Version 4, Src: 20.1.1.2, Dst: 20.1.1.1
- Internet Control Message Protocol

The packet bytes pane shows the raw data of the packet, including the VLAN tag and the ICMP payload.

This captures the VXLAN traffic between 172.1.1.1 and 172.1.1.2 with the VLAN 100 tag inside.

Virtual wire pair with VXLAN

Virtual wire pairs can be used with VXLAN interfaces.

In these examples, VXLAN interfaces are added between FortiGate HQ1 and FortiGate HQ2, a virtual wire pair is added in HQ1, and firewall policies are created on both HQ1 and HQ2.

To create VXLAN interface on HQ1:

```

config system interface
    edit "port11"
        set vdom "root"
        set ip 10.2.2.1 255.255.255.0
        set allowaccess ping https ssh snmp telnet
    next
end
config system vxlan
    edit "vxlan1"
        set interface "port11"
        set vni 1000
        set remote-ip "10.2.2.2"
    next
end

```

To create VXLAN interface on HQ2:

```

config system interface
    edit "port11"
        set vdom "root"
        set ip 10.2.2.2 255.255.255.0
        set allowaccess ping https ssh snmp http
    next
end
config system vxlan
    edit "vxlan1"
        set interface "port11"
        set vni 1000
        set remote-ip "10.2.2.1"
    next
end
config system interface
    edit "vxlan1"
        set vdom "root"
        set ip 10.1.100.2 255.255.255.0
        set allowaccess ping https ssh snmp
    next
end

```

To create a virtual wire pair on HQ1:

```

config system virtual-wire-pair
    edit "vwp1"
        set member "port10" "vxlan1"
    next
end

```

```
    next
end
```

To create a firewall policy on HQ1:

```
config firewall policy
    edit 5
        set name "vxlan-policy"
        set srcintf "port10" "vxlan1"
        set dstintf "port10" "vxlan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set av-profile "default"
        set webfilter-profile "default"
        set dnsfilter-profile "default"
        set ips-sensor "default"
        set application-list "default"
        set fsso disable
    next
end
```

To create a firewall policy on HQ2:

```
config firewall policy
    edit 5
        set name "1"
        set srcintf "port13"
        set dstintf "vxlan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set fsso disable
        set nat enable
    next
end
```

VXLAN over IPsec tunnel with virtual wire pair

VXLAN can be used to encapsulate VLAN traffic over a Layer 3 network. Using IPsec VPN tunnels to secure a connection between two sites, VXLAN can encapsulate VLAN traffic over the VPN tunnel to extend the VLANs between the two sites.

In this example, a site-to-site VPN tunnel is formed between two FortiGates. A VXLAN is configured over the IPsec interface. Multiple VLANs are connected to a switch behind each FortiGate. Host1 and Host2 are connected to VLAN10 on the switches on each site, and Host21 and Host22 are connected to VLAN20. Using virtual wire pairs, the internal interface (port1) will be paired with the VXLAN interface (vxlan) to allow VLAN traffic to pass through in either direction.

To configure FGT-A:

1. Configure the WAN interface:

```
config system interface
  edit "wan1"
    set vdom "root"
    set ip 11.11.11.11 255.255.255.0
    set allowaccess ping https ssh http fgfm
    set type physical
    set role wan
    set snmp-index 1
  next
end
```

2. Configure a static route to send all traffic out the WAN interface:

```
config router static
  edit 1
    set gateway 11.11.11.1
    set device "wan1"
  next
end
```

3. Configure the IPsec tunnel:

```
config vpn ipsec phase1-interface
  edit "ipsec"
    set interface "wan1"
    set peertype any
    set proposal aes256-sha1
    set remote-gw 22.22.22.22
    set psksecret *****
  next
end
config vpn ipsec phase2-interface
  edit "ipsec"
    set phase1name "ipsec"
    set proposal aes256-sha1
```

```

        set auto-negotiate enable
    next
end

```

4. Configure local and remote IP addresses for the IPsec interface:

```

config system interface
    edit "ipsec"
        set ip 10.200.0.1 255.255.255.255
        set remote-ip 10.200.0.2 255.255.255.252
    next
end

```

5. Configure the VXLAN interface and bind it to the IPsec interface:

```

config system vxlan
    edit "vxlan"
        set interface "ipsec"
        set vni 10
        set remote-ip "10.200.0.2"
    next
end

```

The remote IP address is the address of the remote IPsec peer.

6. Configure a virtual wire pair with the port1 and vxlan interfaces as members:

```

config system virtual-wire-pair
    edit "vwp"
        set member "port1" "vxlan"
        set wildcard-vlan enable
    next
end

```

The interfaces added to the virtual wire pair cannot be part of a switch, such as the default internal interface.

By enabling wildcard VLANs on the virtual wire pair, all VLAN tagged traffic that is allowed by the virtual wire pair firewall policies passes through the pair.

7. Configure a virtual wire pair firewall policy to allow traffic between the port1 and vxlan interfaces:

```

config firewall policy
    edit 4
        set name "vwp-pol"
        set srcintf "port1" "vxlan"
        set dstintf "port1" "vxlan"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
    next
end

```

To configure FGT-B

1. Configure the WAN interface:

```

config system interface
    edit "wan1"
        set vdom "root"

```

```
        set ip 22.22.22.22 255.255.255.0 255.255.255.0
        set allowaccess ping https ssh http fgfm
        set type physical
        set role wan
        set snmp-index 1
    next
end
```

2. Configure a static route to send all traffic out the WAN interface:

```
config router static
    edit 1
        set gateway 22.22.22.2
        set device "wan1"
    next
end
```

3. Configure the IPsec tunnel:

```
config vpn ipsec phase1-interface
    edit "ipsec"
        set interface "wan1"
        set peertype any
        set proposal aes256-sha1
        set remote-gw 11.11.11.11
        set psksecret *****
    next
end
config vpn ipsec phase2-interface
    edit "ipsec"
        set phase1name "ipsec"
        set proposal aes256-sha1
        set auto-negotiate enable
    next
end
```

4. Configure local and remote IP addresses for the IPsec interface:

```
config system interface
    edit "ipsec"
        set ip 10.200.0.2 255.255.255.255
        set remote-ip 10.200.0.1 255.255.255.252
    next
end
```

5. Configure the VXLAN interface and bind it to the IPsec interface:

```
config system vxlan
    edit "vxlan"
        set interface "ipsec"
        set vni 10
        set remote-ip "10.200.0.1"
    next
end
```

The remote IP address is the address of the remote IPsec peer.

6. Configure a virtual wire pair with the port1 and vxlan interfaces as members:

```
config system virtual-wire-pair
  edit "vwp"
    set member "port1" "vxlan"
    set wildcard-vlan enable
  next
end
```

7. Configure a firewall policy to allow traffic between the port1 and vxlan interfaces:

```
config firewall policy
  edit 4
    set name "vwp-pol"
    set srcintf "port1" "vxlan"
    set dstintf "port1" "vxlan"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
  next
end
```

Test the configuration

To test the configuration, ping Host2 (VLAN10: 192.168.10.2/24) from Host1 (VLAN10: 192.168.10.1/24):

```
C:\>ping 192.168.10.2
```

```
Pinging 192.168.10.2 with 32 bytes of data:
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=11ms TTL=56

Ping statistics for 192.168.10.2:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 8ms, Maximum = 11ms, Average = 8ms
```

Host21 should also be able to ping Host22.

VXLAN over IPsec using a VXLAN tunnel endpoint

This example describes how to implement VXLAN over IPsec VPN using a VXLAN tunnel endpoint (VTEP).

This example uses a hub and spoke topology. Dialup VPN is used because it allows a single phase 1 dialup definition on the hub FortiGate. Additional spoke tunnels are added with minimal changes to the hub by adding a user account and VXLAN interface for each spoke. Spoke-to-spoke communication is established through the hub. This example assumes that the authentication users and user groups have already been created. While this topology demonstrates hub and spoke with dialup tunnels with XAuth authentication, the same logic can be applied to a static VPN with or without XAuth.

IPsec tunnel interfaces are used to support VXLAN tunnel termination. An IP address is set for each tunnel interface. Ping access is allowed for troubleshooting purposes.

VTEPs are created on the hub and each spoke to forward VXLAN traffic through the IPsec tunnels. VXLAN encapsulates OSI layer 2 Ethernet frames within layer 3 IP packets. You will need to either combine the internal port1 and VXLAN interface into a soft switch, or create a virtual wire pair so that devices behind port1 have direct layer 2 access to remote peers over the VXLAN tunnel. This example uses a switch interface on the hub and a virtual wire pair on the spokes to demonstrate the two different methods.

In order to apply an IPsec VPN interface on the VXLAN interface setting, `net-device` must be disabled in the IPsec VPN phase 1 settings.

To configure the hub FortiGate:

1. Configure the IPsec phase 1 interface:

```
config vpn ipsec phase1-interface
  edit "SPOKES"
    set type dynamic
    set interface "port2"
    set mode aggressive
    set peertype one
    set net-device disable
    set proposal aes256-sha256
    set xauthtype auto
    set authusrgrp "SPOKES"
    set peerid "SPOKES"
    set psksecret <secret>
  next
end
```

2. Configure the IPsec phase 2 interface:

```
config vpn ipsec phase2-interface
    edit "SPOKES"
        set phase1name "SPOKES"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
        aes256gcm chacha20poly1305
    next
end
```

3. Configure the IPsec VPN policy that allows VXLAN traffic between the spokes:

```
config firewall policy
    edit 1
        set name "VXLAN_SPOKE_to_SPOKE"
        set srcintf "SPOKES"
        set dstintf "SPOKES"
        set srcaddr "NET_192.168.255.0"
        set dstaddr "NET_192.168.255.0"
        set action accept
        set schedule "always"
        set service "UDP_4789"
        set logtraffic all
        set fsso disable
    next
end
```

4. Configure the IPsec tunnel interfaces (the remote IP address is not used, but it is necessary for this configuration):

```
config system interface
    edit "SPOKES"
        set vdom "root"
        set ip 192.168.255.1 255.255.255.255
        set allowaccess ping
        set type tunnel
        set remote-ip 192.168.255.254 255.255.255.0
        set snmp-index 12
        set interface "port2"
    next
end
```

5. Configure the VXLAN interfaces. Each spoke requires a VXLAN interface with a different VNI. The remote IP is the tunnel interfaces IP of the spokes.**a. Spoke 1:**

```
config system VXLAN
    edit "SPOKES_VXLAN1"
        set interface "SPOKES"
        set vni 1
        set remote-ip "192.168.255.2"
    next
end
```

b. Spoke 2:

```
config system VXLAN
    edit "SPOKES_VXLAN2"
        set interface "SPOKES"
        set vni 2
```

```
        set remote-ip "192.168.255.3"
    next
end
```

To configure the spoke FortiGate:

1. Configure the IPsec phase 1 interface:

```
config vpn ipsec phase1-interface
    edit "HUB"
        set interface "port2"
        set mode aggressive
        set peertype any
        set net-device disable
        set proposal aes256-sha256
        set localid "SPOKES"
        set xauthtype client
        set authusr "SPOKE1"
        set authpasswd <secret>
        set remote-gw <hub public IP>
        set psksecret <secret>
    next
end
```

2. Configure the IPsec phase 2 interface:

```
config vpn ipsec phase2-interface
    edit "HUB"
        set phase1name "HUB"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set auto-negotiate enable
        set src-subnet 192.168.255.2 255.255.255.255
    next
end
```

The hub FortiGate inserts a reverse route pointing to newly established tunnel interfaces for any of the subnets that the spoke FortiGate's source quick mode selectors provides. This is why you should set the tunnel IP address here.

3. Configure the IPsec VPN policy:

```
config firewall policy
    edit 1
        set name "VTEP_IPSEC_POLICY"
        set srcintf "HUB"
        set dstintf "HUB"
        set srcaddr "none"
        set dstaddr "none"
        set action accept
        set schedule "always"
        set service "PING"
        set logtraffic disable
        set fsso disable
    next
end
```

4. Configure the IPsec tunnel interface:

```
config system interface
  edit "HUB"
    set vdom "root"
    set ip 192.168.255.2 255.255.255.255
    set allowaccess ping
    set type tunnel
    set remote-ip 192.168.255.1 255.255.255.0
    set snmp-index 12
    set interface "port2"
  next
end
```

5. Configure the VXLAN interfaces (the remote IP is the tunnel interface IP of the hub):**a. Spoke 1:**

```
config system VXLAN
  edit "HUB_VXLAN"
    set interface "HUB"
    set vni 1
    set remote-ip "192.168.255.1"
  next
end
```

b. Spoke 2:

```
config system VXLAN
  edit "HUB_VXLAN"
    set interface "HUB"
    set vni 2
    set remote-ip "192.168.255.1"
  next
end
```

To bind the VXLAN interface to the internal interface:**1. Configure a switch interface on the hub:**

```
config system switch-interface
  edit "SW"
    set vdom "root"
    set member "port1" "SPOKES_VXLAN1" "SPOKES_VXLAN2"
    set intra-switch-policy {implicit | explicit}
  next
end
```

Allowing intra-switch traffic is implicitly allowed by default. Use `set intra-switch-policy explicit` to require firewall policies to allow traffic between switch interfaces.

2. Configure a virtual wire pair on the spokes:

```
config system virtual-wire-pair
  edit "VWP"
    set member "HUB_VXLAN" "port1"
```

```
next
end
```

The virtual wire pair requires an explicit policy to allow traffic between interfaces.

To test the configuration:

1. Ping the hub FortiGate from the spoke FortiGate:

```
user@pc-spoke1:~$ ping 192.168.1.1 -c 3
PING 192.168.1.1 (192.168.1.1) 56(84) bytes of data.
64 bytes from 192.168.1.1: icmp_seq=1 ttl=64 time=1.24 ms
64 bytes from 192.168.1.1: icmp_seq=2 ttl=64 time=0.672 ms
64 bytes from 192.168.1.1: icmp_seq=3 ttl=64 time=0.855 ms
--- 192.168.1.1 ping statistics ---
3 packets transmitted, 3 received, 0% packet loss, time 2002 ms
rtt min/avg/max/mdev = 0.672/0.923/1.243/0.239 ms
```

2. Sniff traffic on the hub FortiGate:

```
# diagnose sniffer packet any 'icmp or (udp and port 4789)' 4 0
interfaces=[any] filters=[icmp or (udp and port 4789)]
15:00:01.438230 SPOKES in 192.168.255.2.4790 -> 192.168.255.1.4789: udp 106
15:00:01.438256 SPOKES_VXLAN1 in 192.168.1.2 -> 192.168.1.1: icmp: echo request
15:00:01.438260 port1 out 192.168.1.2 -> 192.168.1.1: icmp: echo request
15:00:01.438532 port1 in 192.168.1.1 -> 192.168.1.2: icmp: echo reply
15:00:01.438536 SPOKES_VXLAN1 out 192.168.1.1 -> 192.168.1.2: icmp: echo reply
15:00:01.438546 SPOKES out 192.168.255.1.4851 -> 192.168.255.2.4789: udp 106
```

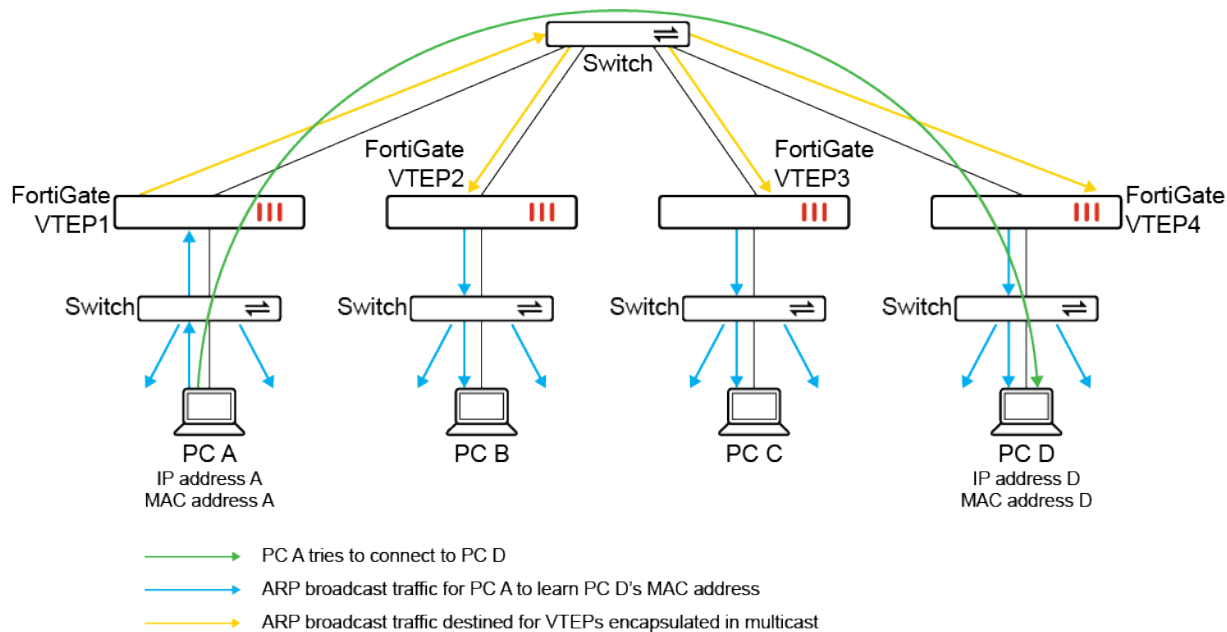

VXLAN with MP-BGP EVPN

FortiOS supports VXLAN as implemented according to [RFC 7348](#). Currently, VXLAN relies on determining the MAC address of the destination host by using address resolution protocol (ARP) broadcast frames encapsulated in multicast packets.

- A multicast group is maintained with all the VXLAN tunnel endpoints (VTEPs) associated with the same VXLAN, namely, with the same VXLAN network identifier (VNI).
- The multicast packets that encapsulate ARP broadcast frames are sent to this multicast group, and then the destination host replies to the source host using unicast IP packet encapsulated using VXLAN.
- The source and destination FortiGates as VTEPs each maintain a mapping of MAC addresses to remote VTEPs.

As with non-VXLAN traffic, VXLAN relies on the preceding ARP process, commonly known as flood-and-learn that floods the network with broadcast frames encapsulated as multicast packets to learn MAC addresses. In the [RFC 7348](#) implementation of VXLAN, the data plane is simultaneously used as a control plane.

The following topology demonstrates how flood-and-learn uses ARP broadcast traffic flooded throughout the VXLAN for PC A to learn PC D's MAC address when PC A tries to connect to PC D.

Multiprotocol Border Gateway Protocol Ethernet Virtual Private Network (MP-BGP EVPN) support for VXLAN allows for learning MAC addresses in a way that is more suitable for large deployments than flood-and-learn.

MP-BGP EVPN is a standards-based control plane that supports the distribution of attached host MAC and IP addresses using MP-BGP, namely, using the EVPN address family and MAC addresses treated as routing entries in BGP. As a control plane that is separate from the data plane, MP-BGP EVPN avoids flood-and-learn in the network, and the wide use of BGP as an external gateway protocol on the internet proves its ability to scale well with large deployments. The following topology demonstrates how MP-BGP EVPN distributes route type 2 MAC/IP advertisement routes among VTEPs in the VXLAN, and minimizes ARP broadcast traffic required for PC A to learn PC D's MAC address when PC A tries to connect to PC D.

MP-BGP EVPN supports the following features:

- Route type 2 (MAC/IP advertisement route) and route type 3 (inclusive multicast Ethernet tag route)
- Intra-subnet communication
- Single-homing use cases
- VLAN-based service, namely, there is only one broadcast domain per EVPN instance (EVI). This is due to the current VXLAN design that supports a single VNI for a VXLAN interface.
- EVPN running on IPv4 unicast VXLAN
- Egress replication for broadcast, unknown unicast, and multicast (BUM) traffic
- VXLAN MAC learning from traffic
- IP address local learning
- ARP suppression

For more information about MP-BGP EVPN, see [RFC 7432](#). For more information about EVPN and VXLAN, see [RFC 8365](#).

Basic MP-BGP EVPN configuration

The MP-BGP EVPN feature builds on the CLI commands used for configuring VXLAN using a VXLAN tunnel endpoint (VTEP). See [General VXLAN configuration and topologies on page 232](#) for more details.

After configuring VXLAN using a VTEP, the following CLI commands are configured to enable MP-BGP EVPN on each VTEP.

To configure MP-BGP EVPN on each VTEP:

1. Configure the EVPN settings:

```
config system evpn
    edit <id>
        set rd {AA | AA:NN | A.B.C.D:NN}
        set import-rt <AA:NN>
        set export-rt <AA:NN>
        set ip-local-learning {enable | disable}
        set arp-suppression {enable | disable}
    next
end
```

The `ip-local-learning` setting is used to enable/disable monitoring the local ARP table of the switch interface to learn the IP/MAC bindings, and advertise them to neighbors. This setting is disabled by default, but must be enabled when configuring MP-BGP EVPN.

The `arp-suppression` setting is used to enable/disable using proxy ARP to perform suppression of ARP discovery using the flood-and-learn approach. This setting is disabled by default. When enabled, proxy ARP entries are added on the switch interface to suppress the ARP flooding of known IP/MAC bindings, which were learned by the MP-BGP EVPN control plane.

2. Configure the EVPN settings within the VXLAN settings:

```
config system vxlan
    edit <name>
        set interface <string>
        set vni <integer>
```

```

        set evpn-id <integer>
        set learn-from-traffic {enable | disable}
    next
end

```

The `learn-from-traffic` setting is used to enable/disable learning of remote VNIs from VXLAN traffic. This setting is disabled by default, and should only be enabled when local and all remote peers are using same VNI value, and some of the peers do not have MP-BGP EVPN capability.

3. Configure the BGP settings:

```

config router bgp
    set ibgp-multipath {enable | disable}
    set recursive-next-hop {enable | disable}
    set graceful-restart {enable | disable}
    config neighbor
        edit <WAN_IP_of_other_VTEP>
            set ebgp-enforce-multihop {enable | disable}
            set next-hop-self {enable | disable}
            set next-hop-self-vpnv4 {enable | disable}
            set soft-reconfiguration {enable | disable}
            set soft-reconfiguration-evpn {enable | disable}
            set remote-as <AS_number>
        next
    end
end

```

4. Configure the EVPN setting within the HA settings:

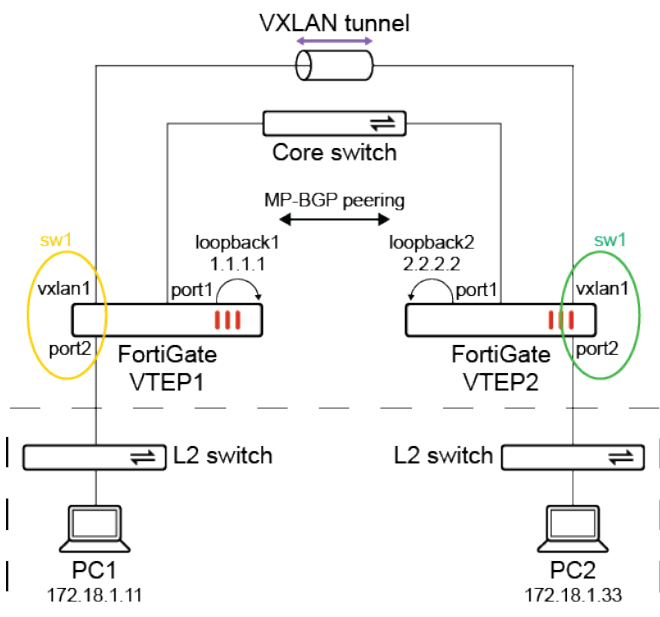

```

config system ha
    set evpn-ttl <integer>
end

```

Example

In this example, two FortiGates are configured as VXLAN tunnel endpoints (VTEPs). A VXLAN is configured to allow L2 connectivity between the networks behind each FortiGate. The VXLAN interface vxlan1 and port2 are placed on the same L2 network using a software switch (sw1). An L2 network is formed between PC1 and PC2. MP-BGP EVPN is used as the control plane to learn and distribute MAC address information within a single L2 domain identified using a specific VNI.

The VTEPs have the following MAC address tables:

Interface/endpoint	VTEP1	VTEP2
vxlan1	82:51:d1:44:bf:93	d2:21:00:c9:e6:98
port2	50:00:00:03:00:01	50:00:00:04:00:01
sw1	50:00:00:03:00:01	50:00:00:04:00:01

The MAC address of PC1 is 00:50:00:00:06:00. The MAC address of PC2 is 00:50:00:00:07:00.

This example assumes that the WAN interface and default route settings have already been configured on the VTEP 1 and VTEP 2 FortiGates. These configurations are omitted from the example. All peers are configured for MP-BGP EVPN.

To configure the VTEP1 FortiGate:

1. Configure the loopback interface:

```
config system interface
  edit "loopback1"
    set vdom "root"
    set ip 1.1.1.1 255.255.255.255
    set allowaccess ping https ssh http
    set type loopback
  next
end
```

2. Configure the EVPN settings:

```
config system evpn
  edit 100
    set rd "100:100"
    set import-rt "1:1"
    set export-rt "1:1"
```

```

        set ip-local-learning enable
        set arp-suppression enable
    next
end

```

3. Configure the local interface and EVPN settings within the VXLAN settings:

```

config system vxlan
    edit "vxlan1"
        set interface "loopback1"
        set vni 1000
        set evpn-id 100
    next
end

```

4. Configure the EVPN settings within the BGP settings:

```

config router bgp
    set as 65001
    set router-id 1.1.1.1
    set ibgp-multipath enable
    set recursive-next-hop enable
    set graceful-restart enable
    config neighbor
        edit "172.25.160.101"
            set ebgp-enforce-multihop enable
            set next-hop-self enable
            set next-hop-self-vpnv4 enable
            set soft-reconfiguration enable
            set soft-reconfiguration-evpn enable
            set remote-as 65001
        next
    end
    config network
        edit 1
            set prefix 1.1.1.1 255.255.255.255
        next
    end
end

```

172.27.16.237 is the WAN IP address of the VTEP2 FortiGate.

5. Configure the software switch:

```

config system switch-interface
    edit "sw1"
        set vdom "root"
        set member "port2" "vxlan1"
        set intra-switch-policy explicit
    next
end

```

6. Configure the software switch interface settings:

```

config system interface
    edit "sw1"
        set vdom "root"
        set ip 172.18.1.253 255.255.255.0
        set allowaccess ping
    end
end

```

```

        set type switch
    next
end

```

7. Configure the firewall policies between the member interfaces in the software switch:

```

config firewall policy
    edit 1
        set srcintf "port2"
        set dstintf "vxlan1"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
    next
    edit 2
        set srcintf "vxlan1"
        set dstintf "port2"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
    next
end

```

To configure the VTEP2 FortiGate:

1. Configure the loopback interface:

```

config system interface
    edit "loopback2"
        set vdom "root"
        set ip 2.2.2.2 255.255.255.255
        set allowaccess ping https ssh http
        set type loopback
    next
end

```

2. Configure the EVPN settings:

```

config system evpn
    edit 100
        set rd "100:100"
        set import-rt "1:1"
        set export-rt "1:1"
        set ip-local-learning enable
        set arp-suppression enable
    next
end

```

3. Configure the local interface and EVPN settings within the VXLAN settings:

```

config system vxlan
    edit "vxlan1"
        set interface "loopback2"
        set vni 1000
    next
end

```

```

        set evpn-id 100
    next
end

```

4. Configure the EVPN settings within the BGP settings:

```

config router bgp
    set as 65001
    set router-id 2.2.2.2
    set ibgp-multipath enable
    set recursive-next-hop enable
    set graceful-restart enable
    config neighbor
        edit "172.25.160.100"
            set ebgp-enforce-multihop enable
            set next-hop-self enable
            set next-hop-self-ipv4 enable
            set soft-reconfiguration enable
            set soft-reconfiguration-evpn enable
            set remote-as 65001
        next
    end
    config network
        edit 1
            set prefix 2.2.2.2 255.255.255.255
        next
    end
end

```

172.27.16.236 is the WAN IP address of the VTEP1 FortiGate.

5. Configure the software switch:

```

config system switch-interface
    edit "sw1"
        set vdom "root"
        set member "port2" "vxlan1"
        set intra-switch-policy explicit
    next
end

```

6. Configure the software switch interface settings:

```

config system interface
    edit "sw1"
        set vdom "root"
        set ip 172.18.1.254 255.255.255.0
        set allowaccess ping
        set type switch
    next
end

```

7. Configure the firewall policies between the member interfaces in the software switch:

```

config firewall policy
    edit 1
        set srcintf "port2"
        set dstintf "vxlan1"
        set action accept
    next
end

```

```

        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
    next
edit 2
    set srcintf "vxlan1"
    set dstintf "port2"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set schedule "always"
    set service "ALL"
next
end

```

To verify the MP-BGP EVPN status on the VTEP1 FortiGate:

1. From a host computer with IP address 172.18.1.11, perform the following.

- a. Check the ARP cache:

```

# arp
Address                  HWtype  HWaddress           Flags Mask            Iface
172.18.1.253             ether    50:00:00:03:00:01    C                      ens3

```

- b. Ping the host computer with IP address 172.18.1.33:

```

# ping 172.18.1.33 -c 4
PING 172.18.1.33 (172.18.1.33) 56(84) bytes of data.
64 bytes from 172.18.1.33: icmp_seq=1 ttl=64 time=1325 ms
64 bytes from 172.18.1.33: icmp_seq=2 ttl=64 time=319 ms
64 bytes from 172.18.1.33: icmp_seq=3 ttl=64 time=3.96 ms
64 bytes from 172.18.1.33: icmp_seq=4 ttl=64 time=1.66 ms

--- 172.18.1.33 ping statistics ---
4 packets transmitted, 4 received, 0% packet loss, time 3007ms
rtt min/avg/max/mdev = 1.660/412.614/1325.209/542.530 ms

```

- c. Check the ARP cache again:

```

# arp
Address                  HWtype  HWaddress           Flags Mask            Iface
172.18.1.33             ether    00:50:00:00:07:00    C                      ens3
172.18.1.253             ether    50:00:00:03:00:01    C                      ens3

```

2. On the VTEP1 FortiGate, run the switch and VXLAN debug commands.

- a. Verify the forwarding database for vxlan1:

```

# diagnose sys vxlan fdb list vxlan1
mac=00:00:00:00:00:00 state=0x0082 remote_ip=2.2.2.2 port=4789 vni=1000 ifindex0
mac=00:50:00:00:07:00 state=0x0082 remote_ip=2.2.2.2 port=4789 vni=1000 ifindex0

total fdb num: 2

```

- b. Verify the forwarding database statistics for vxlan1:

```

# diagnose sys vxlan fdb stat vxlan1
fdb_table_size=256 fdb_table_used=2 fdb_entry=2 fdb_max_depth=1 cleanup_idx=0 c2

```

c. Verify the bridging information for sw1:

```
# diagnose netlink brctl name host sw1
show bridge control interface sw1 host.
fdb: hash size=32768, used=5, num=5, depth=1, gc_time=4, ageing_time=3, arp-sup
Bridge sw1 host table
port no device devname mac addr ttl attributes
2 15 vxlan1 00:00:00:00:00:00 28 Hit(28)
2 15 vxlan1 00:50:00:00:07:00 18 Hit(18)
2 15 vxlan1 82:51:d1:44:bf:93 0 Local Static
1 4 port2 00:50:00:00:06:00 14 Hit(14)
1 4 port2 50:00:00:03:00:01 0 Local Static
```

3. Run the BGP EVPN commands and observe the route type 2 (MAC/IP advertisement route) and route type 3 (inclusive multicast Ethernet tag route).

a. Verify the BGP L2 VPN EVPN summary information:

```
# get router info bgp evpn summary

VRF 0 BGP router identifier 1.1.1.1, local AS number 65001
BGP table version is 2
1 BGP AS-PATH entries
0 BGP community entries

Neighbor V AS MsgRcvd MsgSent TblVer InQ OutQ Up/Down State/Pd
172.25.160.101 4 65001 9 9 1 0 0 00:04:02 3

Total number of neighbors 1
```

b. Verify the BGP L2 VPN EVPN network information:

```
# get router info bgp evpn network
Network Next Hop Metric LocPrf Weight RouteTag Path
Route Distinguisher: 100:100 (Default for VRF 0)
*> [2][0][48][00:50:00:00:06:00][0]/72
1.1.1.1 0 100 32768 0 i <-/>
*> [2][0][48][00:50:00:00:06:00][32][172.18.1.11]/104
1.1.1.1 0 100 32768 0 i <-/>
*>i[2][0][48][00:50:00:00:07:00][0]/72
2.2.2.2 0 100 0 0 i <-/>
*>i[2][0][48][00:50:00:00:07:00][32][172.18.1.33]/104

*>i[3][0][32][2.2.2.2]/80
2.2.2.2 0 100 0 0 i <-/>
```

c. Verify the BGP L2 VPN EVPN context:

```
# get router info bgp evpn context
L2VPN EVPN context for VRF 0
ID 100 vlan-based, RD is [100:100]
Import RT: RT:1:1
Export RT: RT:1:1
Bridge domain 0 VNI 1000
Encapsulation 8 (VXLAN)
Source interface loopback1
Source address 1.1.1.1
```

d. Verify the BGP L2 VPN EVPN information for VRF 0:

```
# get router info bgp evpn vrf 0
Network          Next Hop          Metric      LocPrf Weight RouteTag Path
Route Distinguisher: 100:100 (Default for VRF 0)
*> [2][0][48][00:50:00:00:06:00][0]/72

Total number of prefixes 6

4. Run the following EVPN get commands.

a. Verify the EVPN instances:

```
# get l2vpn evpn instance
EVPN instance: 100
IP local learning enabled
ARP suppression enabled
HA primary
  Number of bridge domain: 1
  Bridge domain: TAGID 0 VNI 1000 ADDR 1.1.1.1 VXLAN vxlan1 SWITCH sw1
```

b. Verify the EVPN table:

```
# get l2vpn evpn table
EVPN instance 100
Broadcast domain VNI 1000 TAGID 0

EVPN instance 100
Broadcast domain VNI 1000 TAGID 0

EVPN MAC table:
MAC          VNI      Remote Addr    Binded Address
00:50:00:00:07:00 1000    2.2.2.2        172.18.1.33
                1000    2.2.2.2        -

EVPN IP table:
Address      VNI      Remote Addr    MAC
172.18.1.33 1000    2.2.2.2        00:50:00:00:07:00

EVPN Local MAC table:
"Inactive" means this MAC/IP pair will not be sent to peer.
Flag code: S - Static F - FDB. Trailing * means HA
MAC          Flag Status    Binded Address
00:50:00:00:06:00      Active  172.18.1.11
                F      Active  -

EVPN Local IP table:
Address      MAC
172.18.1.11 00:50:00:00:06:00

EVPN PEER table:
VNI      Remote Addr    Binded Address
1000     2.2.2.2        2.2.2.2
```

5. Run the proxy ARP diagnose command:

```
# diagnose ip parp list
Address      Hardware Addr    Interface
172.18.1.33  00:50:00:00:07:00 sw1
```

VXLAN troubleshooting

The following commands can be used to troubleshoot VXLAN connectivity:

- `diagnose sys vxlan fdb list <VXLAN_interface>`
- `diagnose sys vxlan fdb stat <VXLAN_interface>`
- `diagnose netlink brctl name host <switch_interface>`
- `diagnose debug sniffer packet any 'udp and port 4789' 4 0 1`
- `diagnose debug enable`
- `diagnose debug flow filter port 4789`
- `diagnose debug flow trace start <repeat_#>`

Topology

The following topology is used as an example configuration to demonstrate VXLAN troubleshooting steps.

In this example, two FortiGates are configured as VXLAN tunnel endpoints (VTEPs). A VXLAN is configured to allow L2 connectivity between the networks behind each FortiGate. The VXLAN interface and port6 are placed on the same L2 network using a software switch (sw100). An L2 network is formed between PC1 and PC2.

The VTEPs have the following MAC address tables:

Interface/endpoint	VTEP 1	VTEP 2
vlan100	7e:f2:d1:84:75:0f	ca:fa:31:23:8d:c1
port6	00:0c:29:4e:5c:1c	00:0c:29:d0:3e:0d
sw100	00:0c:29:4e:5c:1c	00:0c:29:d0:3e:0d

The MAC address of PC1 is 00:0c:29:90:4f:bf. The MAC address of PC2 is 00:0c:29:f0:88:2c.

To configure the VTEP 1 FortiGate:

1. Configure the local interface:

```
config system vxlan
  edit "vxlan100"
    set interface "port2"
    set vni 100
    set remote-ip "192.168.2.87"
  next
end
```

2. Configure the interface settings:

```
config system interface
  edit "port2"
    set vdom "root"
    set ip 192.168.2.86 255.255.255.0
    set allowaccess ping https ssh http fabric
  next
  edit "vxlan100"
    set vdom "root"
    set type vxlan
    set interface "port2"
  next
end
```

3. Configure the software switch:

```
config system switch-interface
  edit "sw100"
    set vdom "root"
    set member "port6" "vxlan100"
  next
end
```

4. Configure the software switch interface settings:

```
config system interface
  edit "sw100"
    set vdom "root"
    set ip 10.10.100.86 255.255.255.0
    set allowaccess ping
    set type switch
    set device-identification enable
    set lldp-transmission enable
```

```
        set role lan
    next
end
```

To configure the VTEP 2 FortiGate:

1. Configure the local interface:

```
config system vxlan
    edit "vxlan100"
        set interface "port2"
        set vni 100
        set remote-ip "192.168.2.86"
    next
end
```

2. Configure the interface settings:

```
config system interface
    edit "port2"
        set vdom "root"
        set ip 192.168.2.87 255.255.255.0
        set allowaccess ping https ssh snmp http
    next
    edit "vxlan100"
        set vdom "root"
        set type vxlan
        set interface "port2"
    next
end
```

3. Configure the software switch:

```
config system switch-interface
    edit "sw100"
        set vdom "root"
        set member "port6" "vxlan100"
    next
end
```

4. Configure the software switch interface settings:

```
config system interface
    edit "sw100"
        set vdom "root"
        set ip 10.10.100.87 255.255.255.0
        set allowaccess ping
        set type switch
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 42
    next
end
```

To run diagnostics and debugs:**1. Start a ping from PC1 10.10.100.10 to PC2 10.10.100.20:**

```
C:\Users\fortidocs>ping 10.10.100.20

Pinging 10.10.100.20 with 32 bytes of data:
Reply from 10.10.100.20: bytes=32 time=2ms TTL=128
Reply from 10.10.100.20: bytes=32 time=1ms TTL=128
Reply from 10.10.100.20: bytes=32 time=1ms TTL=128
Reply from 10.10.100.20: bytes=32 time<1ms TTL=128

Ping statistics for 10.10.100.20:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 0ms, Maximum = 2ms, Average = 1ms
```

2. Verify the ARP table:

```
C:\Users\fortidocs>arp /a

Interface: 10.10.100.10 --- 0x21
    Internet Address      Physical Address      Type
    10.10.100.20          00-0c-29-f0-88-2c    dynamic
    10.10.100.86          00-0c-29-4e-5c-1c    dynamic
    10.10.100.255         ff-ff-ff-ff-ff-ff    static
    224.0.0.22            01-00-5e-00-00-16    static
    224.0.0.252           01-00-5e-00-00-fc    static
```

3. Run diagnostics on the VTEP 1 FortiGate.**a. Verify the forwarding database of VXLAN interface vxlan100:**

```
# diagnose sys vxlan fdb list vxlan100
mac=00:00:00:00:00:00 state=0x0082 remote_ip=192.168.2.87 port=4789 vni=100 ifindex=6
mac=00:0c:29:f0:88:2c state=0x0002 remote_ip=192.168.2.87 port=4789 vni=100 ifindex=6

total fdb num: 2
```

The MAC address 00:0c:29:f0:88:2c is learned from PC2 10.10.100.20.

b. Verify the summary of statistics from the VXLAN's forwarding database:

```
# diagnose sys vxlan fdb stat vxlan100
fdb_table_size=256 fdb_table_used=2 fdb_entry=2 fdb_max_depth=1 cleanup_idx=0
cleanup_timer=252
```

c. Verify the software switch's forwarding table:

```
# diagnose netlink brctl name host sw100
show bridge control interface sw100 host.
fdb: hash size=32768, used=6, num=6, depth=1, gc_time=4, ageing_time=3, simple=switch
Bridge sw100 host table
```

port	no	device	devname	mac	addr	tvl	attributes
1	7	port6	00:0c:29:4e:5c:1c	0		Local Static	
2	33	vxlan100	7e:f2:d1:84:75:0f	0		Local Static	
2	33	vxlan100	00:00:00:00:00:00	26		Hit (26)	
1	7	port6	00:0c:29:90:4f:bf	0		Hit (0)	
1	7	port6	00:0c:29:d0:3e:ef	7		Hit (7)	
2	33	vxlan100	00:0c:29:f0:88:2c	0		Hit (0)	

The MAC address of port6 is 00:0c:29:4e:5c:1c. The MAC address of vxlan100 is 7e:f2:d1:84:75:0f. The MAC address 00:0c:29:f0:88:2c of PC2 is learned from the remote network.

4. Run diagnostics on the VTEP 2 FortiGate.

a. Verify the forwarding database of VXLAN interface vxlan100:

```
# diagnose sys vxlan fdb list vxlan100
mac=00:00:00:00:00:00 state=0x0082 remote_ip=192.168.2.86 port=4789 vni=100 ifindex=6
mac=00:0c:29:90:4f:bf state=0x0002 remote_ip=192.168.2.86 port=4789 vni=100 ifindex=6

total fdb num: 2
```

The MAC address 00:0c:29:90:4f:bf is learned from PC1 10.10.100.10.

b. Verify the summary of statistics from the VXLAN's forwarding database:

```
# diagnose sys vxlan fdb stat vxlan100
fdb_table_size=256 fdb_table_used=2 fdb_entry=2 fdb_max_depth=1 cleanup_idx=0
cleanup_timer=304
```

c. Verify the software switch's forwarding table:

```
# diagnose netlink brctl name host sw100
show bridge control interface sw100 host.
fdb: hash size=32768, used=5, num=5, depth=1, gc_time=4, ageing_time=3, simple=switch
Bridge sw100 host table
```

port	no	device	devname	mac	addr	ttl	attributes
2	50	vxlan100		00:00:00:00:00:00		10	Hit(10)
2	50	vxlan100		00:0c:29:90:4f:bf		2	Hit(2)
1	7	port6		00:0c:29:d0:3e:0d		0	Local Static
2	50	vxlan100		ca:fa:31:23:8d:c1		0	Local Static
1	7	port6		00:0c:29:f0:88:2c		0	Hit(0)

The MAC address of port6 is 00:0c:29:d0:3e:0d. The MAC address of vxlan100 is ca:fa:31:23:8d:c1. The MAC address 00:0c:29:90:4f:bf of PC1 is learned from the remote network.

5. Perform a sniffer trace on the VTEP 1 FortiGate to view the life of the packets as they pass through the FortiGate:

```
# diagnose sniffer packet any 'host 10.10.100.20 or (udp and host 192.168.2.87)' 4 0 1
Using Original Sniffing Mode
interfaces=[any]
filters=[host 10.10.100.20 or (udp and host 192.168.2.87)]
2022-11-04 14:35:18.567602 port6 in arp who-has 10.10.100.20 tell 10.10.100.10
2022-11-04 14:35:18.567629 vxlan100 out arp who-has 10.10.100.20 tell 10.10.100.10
2022-11-04 14:35:18.567642 port2 out 192.168.2.86.4804 -> 192.168.2.87.4789: udp 68

2022-11-04 14:35:18.568945 sw100 in arp who-has 10.10.100.10 tell 10.10.100.20
2022-11-04 14:35:18.569070 port6 in arp reply 10.10.100.10 is-at 00:0c:29:90:4f:bf
2022-11-04 14:35:18.569076 vxlan100 out arp reply 10.10.100.10 is-at 00:0c:29:90:4f:bf
2022-11-04 14:35:18.569081 port2 out 192.168.2.86.4806 -> 192.168.2.87.4789: udp 68
2022-11-04 14:35:18.569417 port2 in 192.168.2.87.4789 -> 192.168.2.86.4789: udp 82
```

```
2022-11-04 14:35:18.569427 vxlan100 in 10.10.100.20 -> 10.10.100.10: icmp: echo reply
2022-11-04 14:35:18.569431 port6 out 10.10.100.20 -> 10.10.100.10: icmp: echo reply
```

In the output, the following packet sequence is seen on the FortiGate:

- a. The FortiGate receives an ARP request from PC1 10.10.100.10 on port6.
 - b. The ARP request is forwarded to vxlan100 on the same software switch, where it gets encapsulated and sent out as a UDP port 4789 packet on port2.
 - c. A reply is received on port2 from the remote VTEP with the ARP response encapsulated in UDP port 4789 again.
 - d. The ARP reply is forwarded back out of port6 to PC1.
 - e. PC1 sends the ICMP request using the same steps.
6. Perform the same sniffer trace filter with a level 6 verbose level. In this example, the packet capture is converted into a Wireshark file.

No.	Time	Source	Destination	Protocol	Length	Info
1	21:46:13.018875	Vmware_90:4f:bf	Broadcast	ARP	60	Who has 10.10.100.20? Tell 10.10.100.10

VXLAN Network Identifier (VNI) (vxlan.vni), 3 bytes

Packets: 28 · Displayed: 28 (100.0%)

Profile: Default

The packet that leaves the physical port2 is encapsulated in UDP and has a VXLAN header with VNI 100 as the identifier. There is an additional 50 B overhead of the UDP encapsulated VXLAN packets as opposed to the unencapsulated packets (for example, packet 4 versus packets 1 and 2).

DNS

Domain name system (DNS) is used by devices to locate websites by mapping a domain name to a website's IP address.

A FortiGate can serve different roles based on user requirements:

- A FortiGate can control what DNS server a network uses.
- A FortiGate can function as a DNS server.

FortiGuard Dynamic DNS (DDNS) allows a remote administrator to access a FortiGate's Internet-facing interface using a domain name that remains constant even when its IP address changes.

FortiOS supports DNS configuration for both IPv4 and IPv6 addressing. When a user requests a website, the FortiGate looks to the configured DNS servers to provide the IP address of the website in order to know which server to contact to complete the transaction.

The FortiGate queries the DNS servers whenever it needs to resolve a domain name into an IP address, such as for NTP or web servers defined by their domain names.

The following topics provide information about DNS:

- [Important DNS CLI commands on page 269](#)
- [DNS domain list on page 272](#)
- [FortiGate DNS server on page 274](#)
- [DDNS on page 276](#)
- [DNS latency information on page 280](#)
- [DNS over TLS and HTTPS on page 282](#)
- [Transparent conditional DNS forwarder NEW on page 286](#)
- [DNS troubleshooting on page 290](#)

Important DNS CLI commands

DNS settings can be configured with the following CLI command:

```
config system dns
    set primary <ip_address>
    set secondary <ip_address>
    set protocol {cleartext dot doh}
    set ssl-certificate <string>
    set server-hostname <hostname>
    set domain <domains>
    set ip6-primary <ip6_address>
    set ip6-secondary <ip6_address>
    set timeout <integer>
    set retry <integer>
    set dns-cache-limit <integer>
    set dns-cache-ttl <integer>
    set cache-notfound-responses {enable | disable}
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
    set source-ip <class_ip>
    set server-select-method {least-rtt | failover}
    set alt-primary <ip_address>
    set alt-secondary <ip_address>
    set log {disable |error | all}
    set fqdn-cache-ttl <integer>
    set fqdn-min-refresh <integer>
    set fqdn-max-refresh <integer>
end
```

For a FortiGate with multiple logical CPUs, you can set the DNS process number from 1 to the number of logical CPUs. The default DNS process number is 1.

```
config system global
    set dnsproxy-worker-count <integer>
end
```

DNS protocols

The following DNS protocols can be enabled:

- `cleartext`: Enable clear text DNS over port 53 (default).
- `dot`: Enable DNS over TLS.
- `doh`: Enable DNS over HTTPS.

For more information, see [DNS over TLS and HTTPS on page 282](#).

cache-notfound-responses

When enabled, any DNS requests that are returned with `NOT FOUND` can be stored in the cache. The DNS server is not asked to resolve the host name for `NOT FOUND` entries. By default, this option is disabled.

dns-cache-limit

Set the number of DNS entries that are stored in the cache (0 to 4294967295, default = 5000). Entries that remain in the cache provide a quicker response to requests than going out to the Internet to get the same information.

dns-cache-ttl

The duration that the DNS cache retains information, in seconds (60 to 86400 (1 day), default = 1800).

fqdn-cache-ttl

FQDN cache time to live (TTL), in seconds (0 - 86400, default = 0).

This is the amount of time an FQDN's address record can live if not refreshed. This setting applies globally, across all VDOMs, to FQDNs that have unspecified firewall address `cache-ttl` settings. If the `cache-ttl` value is configured for an FQDN address, it will supersede the `fqdn-cache-ttl` setting for that address.

For example, configure the FQDN cache TTL on the global VDOM:

```
config system dns
    set fqdn-cache-ttl 2000
end

# diagnose test application dnsproxy 6

...
vfid=0 name=test.bb.com ver=IPv4 wait_list=0 timer=985 min_ttl=1000 cache_ttl=2000 slot=-1
num=1 wildcard=0
    1.1.1.1 (ttl=1000:991:1991)
vfid=0 name=*.google.com ver=IPv4 wait_list=0 timer=0 min_ttl=0 cache_ttl=2000 slot=-1 num=0
wildcard=
...
```

Change the cache TTL in a VDOM for a specific address:

```
config firewall address
    edit "test.bb.com"
        set cache-ttl 1000
```

```

    next
end

# sudo global diagnose test application dnsproxy 6
...
vfid=0 name=test.bb.com ver=IPv4 wait_list=0 timer=864 min_ttl=1000 cache_ttl=1000 slot=-1
num=1 wildcard=0
1.1.1.1 (ttl=1000:870:1870)
vfid=0 name=*.google.com ver=IPv4 wait_list=0 timer=0 min_ttl=0 cache_ttl=2000 slot=-1 num=0
wildcard=1
...

```

fqdn-min-refresh

FQDN cache minimum refresh time, in seconds (10 - 3600, default = 60).

An FQDN normally requeries for updates according to the lowest TTL interval returned from all the DNS records in a DNS response. The FortiGate has a default minimum refresh interval of 60 seconds; if a TTL interval is shorter than 60 seconds, it still requires a minimum of 60 seconds for the FortiGate to requery for new addresses. The `fqdn-min-refresh` setting changes the interval. The settings could be shortened if there are FQDNs that require fast resolutions based on a short TTL interval.

For example, if `fqdn_min_refresh` is unspecified:

```

# diagnose test application dnsproxy 3
worker idx: 0
...
FQDN: min_refresh=60 max_refresh=3600
...

# diagnose test application dnsproxy 6
worker idx: 0
vfid=0 name=aa.com ver=IPv4 wait_list=0 timer=28 min_ttl=20 cache_ttl=0 slot=-1 num=1
wildcard=0
    23.202.195.114 (ttl=20:0:0)

```

The `min_refresh` is the default value of 60 seconds. Although the `min_ttl` (TTL returned) value is shorter, the FortiGate only requeries for updates based on the `min_refresh` value. the `timer` value is the countdown until the next refresh is triggered. The FortiGate triggers a refresh slightly earlier than the larger of the `min_refresh` or `min_ttl` value.

If `fqdn_min_refresh` is configured:

```

config system dns
    set fqdn-min-refresh 20
end

# diagnose test application dnsproxy 3
worker idx: 0
...
FQDN: min_refresh=20 max_refresh=3600
...

# diagnose test application dnsproxy 6
worker idx: 0
vfid=0 name=aa.com ver=IPv4 wait_list=0 timer=8 min_ttl=20 cache_ttl=0 slot=-1 num=1
wildcard=0
    23.202.195.114 (ttl=20:14:14)

```

This setting can be used in combination with `fqdn-cache-ttl` and `cache-ttl` to send more frequent queries and store more resolved addresses in cache. This is useful in scenarios where the FQDN has many resolutions and changes very frequently.

fqdn-max-refresh

FQDN cache maximum refresh time, in seconds (3600 - 86400, default = 3600).

The `fqdn-max-refresh` setting is used to control the global upper limit of the FQDN refresh timer. FQDN entries with a TTL interval that is longer than the `fqdn-max-refresh` value will have their refresh timer reduced to this upper limit. This allows the FortiGate to dictate the upper limit in querying for DNS updates for its FQDN addresses.

VDOM DNS

When the FortiGate is in multi-vdom mode, DNS is handled by the management VDOM. However in some cases, administrators may want to configure custom DNS settings on a non-management VDOM. For example, in a multi-tenant scenario, each VDOM might be occupied by a different tenant, and each tenant might require its own DNS server.

To configure a custom VDOM within a non-management VDOM:

```
config vdom
edit <vdom>
config system vdom-dns
    set vdom-dns enable
    set primary <primary_DNS>
    set secondary <secondary_DNS>
    set protocol {cleartext dot doh}
    set ip6-primary <primary_IPv6_DNS>
    set ip6-secondary <secondary_IPv6_DNS>
    set source-ip <IP_address>
    set interface-select-method {auto | sdwan | specify}
end
```

DNS domain list

You can configure up to eight domains in the DNS settings using the GUI or the CLI.

When a FortiGate requests a URL that does not include an FQDN, FortiOS resolves the URL by traversing through the DNS domain list and performing a query for each domain until the first match is found.

By default, FortiGates use FortiGuard's DNS servers:

- Primary: 96.45.45.45
- Secondary: 96.45.46.46

You can also customize the DNS timeout time and the number of retry attempts.

To configure a DNS domain list in the GUI:

1. Go to *Network > DNS*.
2. Set *DNS Servers* to *Specify*.
3. Configure the primary and secondary DNS servers as needed.
4. In the *Local Domain Name* field, enter the first domain (*sample.com* in this example).
5. Click the **+** to add more domains (*example.com* and *domainname.com* in this example). You can enter up to eight domains.
6. Configure additional DNS protocol and IPv6 settings as needed.

7. Click *Apply*.

To configure a DNS domain list in the CLI:

```
config system dns
    set primary 96.45.45.45
    set secondary 96.45.46.46
    set domain "sample.com" "example.com" "domainname.com"
end
```

Verify the DNS configuration

In the following example, the local DNS server has the entry for *host1* mapped to the FQDN of *host1.sample.com*, and the entry for *host2* is mapped to the FQDN of *host2.example.com*.

To verify that the DNS domain list is configured:

1. Open the FortiGate CLI.
2. Enter `execute ping host1`.

The system returns the following response:

```
PING host1.sample.com (1.1.1.1): 56 data bytes
```

As the request does not include an FQDN, FortiOS traverses the configured DNS domain list to find a match.

Because *host1* is mapped to the *host1.sample.com*, FortiOS resolves *host1* to *sample.com*, the first entry in the domain list.

3. Enter `execute ping host2`.

The system returns the following response:

```
PING host2.example.com (2.2.2.2): 56 data bytes
```

FortiOS traverses the domain list to find a match. It first queries `sample.com`, the first entry in the domain list, but does not find a match. It then queries the second entry in the domain list, `example.com`. Because `host2` is mapped to the FQDN of `host2.example.com`, FortiOS resolves `host2` to `example.com`.

DNS timeout and retry settings

The DNS timeout and retry settings can be customized using the CLI.

```
config system dns
    set timeout <integer>
    set retry <integer>
end
```

<code>timeout <integer></code>	The DNS query timeout interval, in seconds (1 - 10, default = 5).
<code>retry <integer></code>	The number of times to retry the DNS query (0 - 5, default - 2).

FortiGate DNS server

You can create local DNS servers for your network. Depending on your requirements, you can either manually maintain your entries (primary DNS server), or use it to refer to an outside source (secondary DNS server).

A local, primary DNS server requires that you to manually add all URL and IP address combinations. Using a primary DNS server for local services can minimize inbound and outbound traffic, and access time. Making it authoritative is not recommended, because IP addresses can change, and maintaining the list can become labor intensive.

A secondary DNS server refers to an alternate source to obtain URL and IP address combinations. This is useful when there is a primary DNS server where the entry list is maintained.

FortiGate as a DNS server also supports TLS and HTTPS connections to a DNS client. See [DNS over TLS and HTTPS on page 282](#) for details.

By default, DNS server options are not available in the FortiGate GUI.

To enable DNS server options in the GUI:

1. Go to *System > Feature Visibility*.
2. Enable *DNS Database* in the *Additional Features* section.
3. Click *Apply*.

Example configuration

This section describes how to create an unauthoritative primary DNS server. The interface mode is recursive so that, if the request cannot be fulfilled, the external DNS servers will be queried.

To configure FortiGate as a primary DNS server in the GUI:

1. Go to *Network > DNS Servers*.
2. In the *DNS Database* table, click *Create New*.
3. Set *Type* to *Primary*.
4. Set *View* to *Shadow*.
The *View* setting controls the accessibility of the DNS server. If you select *Public*, external users can access or use the DNS server. If you select *Shadow*, only internal users can use it.
5. Enter a *DNS Zone*, for example, *WebServer*.
6. Enter the *Domain Name* of the zone, for example, *fortinet.com*.
7. Enter the *Hostname* of the DNS server, for example, *Corporate*.
8. Enter the *Contact Email Address* for the administrator, for example, *admin@example.com*.
9. Disable *Authoritative*.

10. Add DNS entries:
 - a. In the *DNS Entries* table, click *Create New*.
 - b. Select a *Type*, for example *Address (A)*.
 - c. Set the *Hostname*, for example *web.example.com*.

- d. Configure the remaining settings as needed. The options vary depending on the selected *Type*.
 - e. Click *OK*.
11. Add more DNS entries as needed.
 12. Click *OK*.
 13. Enable DNS services on an interface:
 - a. Go to *Network > DNS Servers*.
 - b. In the *DNS Service on Interface* table, click *Create New*.
 - c. Select the *Interface* for the DNS server, such as *wan2*.

d. Set the *Mode* to *Recursive*.

e. Click OK.

To configure FortiGate as a primary DNS server in the CLI:

```
config system dns-database
  edit WebServer
    set domain example.com
    set type master
    set view shadow
    set ttl 86400
    set primary-name corporate
    set contact admin@example.com
    set authoritative disable
  config dns-entry
    edit 1
      set status enable
      set hostname web.example.com
      set type A
      set ip 192.168.21.12
    next
  end
next
end

config system dns-server
  edit wan2
    set mode recursive
  next
end
```

DDNS

If your external IP address changes regularly and you want a static domain name, you can configure the external interface to use a dynamic DNS (DDNS) service. This ensures that external users and customers can always connect to your company firewall. You can configure FortiGuard as the DDNS server using the GUI or CLI.

A license or subscription is not required to use the DDNS service, but configuring DDNS in the GUI is not supported if:

- The FortiGate model is a 1000-series or higher.
- The FortiGate is a VM.
- The DNS server is not using FortiGuard as the DNS.

FortiGate does not support DDNS when in transparent mode.

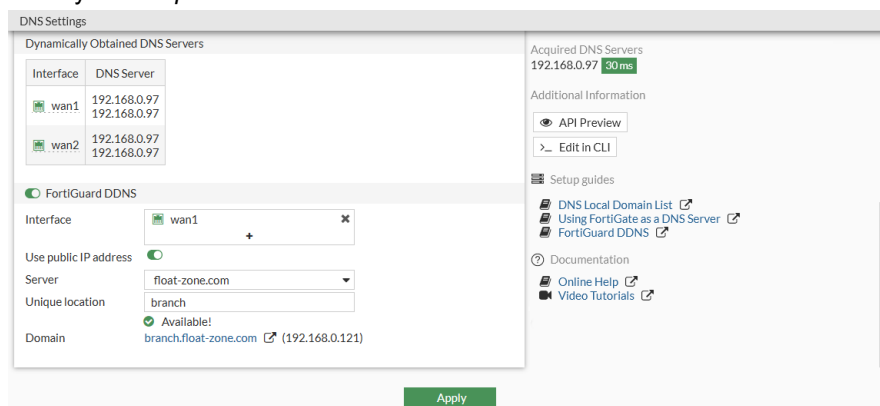

Sample topology

In this example, FortiGuard DDNS is enabled and the DDNS server is set to *float-zone.com*. Other DDNS server options include *fortiddns.com* and *fortidyndns.com*.

To configure FortiGuard DDNS service as a DDNS server in the GUI:

1. Go to *Network > DNS*
2. Enable *FortiGuard DDNS*.
3. Select the *Interface* with the dynamic connection.
4. Select the *Server* that you have an account with.
5. Enter your *Unique Location*.

6. Click *Apply*.

To configure the FortiGuard DDNS service as an IPv4 DDNS server in the CLI:

```

config system ddns
  edit 1
    set ddns-server FortiGuardDDNS
    set server-type ipv4
    set ddns-domain "branch.float-zone.com"
    set addr-type ipv4
    set use-public-ip enable
    set monitor-interface "wan1"
  next
end

```

To configure the FortiGuard DDNS service as an IPv6 DDNS server in the CLI:

```

config system ddns
  edit 1

```

```

        set ddns-server FortiGuardDDNS
        set server-type ipv6
        set ddns-domain "fgtatest001.float-zone.com"
        set addr-type ipv6
        set monitor-interface "wan1"
    next
end

```

DDNS servers other than FortiGuard

If you do not have a FortiGuard subscription, or want to use a different DDNS server, you can configure a DDNS server for each interface. Only the first configure port appears in the GUI.

The available commands vary depending on the selected DDNS server.

To configure DDNS servers other than FortiGuard in the CLI:

```

config system ddns
    edit <DDNS_ID>
        set monitor-interface <external_interface>
        set ddns-server <ddns_server_selection>
        set server-type {ipv4 | ipv6}
        set ddns-server-addr <address>
        set addr-type ipv6 {ipv4 | ipv6}
    next
end

```

To configure an IPv6 DDNS client with generic DDNS on port 3 in the CLI:

```

config system ddns
    edit 1
        set ddns-server genericDDNS
        set server-type ipv6
        set ddns-server-addr "2004:16:16:16::2" "16.16.16.2" "ddns.genericddns.com"
        set ddns-domain "test.com"
        set addr-type ipv6
        set monitor-interface "port3"
    next
end

```

Refresh DDNS IP addresses

When using a public IP that is not assigned to the FortiGate, the FortiGate cannot trigger an update when the IP address changes. The FortiGate can be configured to refresh DDNS IP addresses by periodically checking the DDNS server at an update interval.

To configure FortiGate to refresh DDNS IP addresses in the CLI:

```

config system ddns
    edit 1
        set use-public-ip enable
        set update-interval <seconds>
    next
end

```

```
    next
end
```

When `update-interval` is set to 0:

- For FortiGuard DDNS, the interval is 300 seconds.
- For third part DDNS servers, the interval is assigned by the DDNS server.

Disable cleartext

When `clear-text` is disabled, FortiGate uses the SSL connection to send and receive DDNS updates.

To disable cleartext and set the SSL certificate in the CLI:

```
config system ddns
    edit 2
        set clear-text disable
        set ssl-certificate <cert_name>
    next
end
```

DDNS update override

A DHCP server has an override command option that allows DHCP server communications to go through DDNS to perform updates for the DHCP client. This enforces a DDNS update of the A field every time even if the DHCP client does not request it. This allows support for the `allow`, `ignore`, and `deny` `client-updates` options.

To enable DDNS update override in the CLI:

```
config system dhcp server
    edit 1
        set ddns-update enable
        set ddns-update-override enable
        set ddns-server-ip <ddns_server_ip>
        set ddns-zone <ddns_zone>
    next
end
```

Troubleshooting

To debug DDNS:

```
# diagnose debug application ddnsd -1
# diagnose debug enable
```

To check if a DDNS server is available:

```
# diagnose test application ddnsd 3
```

Not available:

```
FortiDDNS status:
ddns_ip=0.0.0.0, ddns_ip6=::, ddns_port=443 svr_num=0 domain_num=0
```

Available:

```
FortiDDNS status:
ddns_ip=208.91.113.230, ddns_ip6=::, ddns_port=443 svr_num=1 domain_num=3
svr[0]= 208.91.113.230
domain[0]= fortiddns.com
domain[1]= fortidyndns.com
domain[2]= float-zone.com
```

DNS latency information

High latency in DNS traffic can result in an overall sluggish experience for end-users. In the *DNS Settings* pane, you can quickly identify DNS latency issues in your configuration.

Go to *Network > DNS* to view DNS latency information in the right side bar. If you use FortiGuard DNS, latency information for DNS, DNS filter, web filter, and outbreak prevention servers is also visible. Hover your pointer over a latency value to see when it was last updated.

To view DNS latency information using the CLI:

```
# diagnose test application dnsproxy 2
worker idx: 0
worker: count=1 idx=0
retry_interval=500 query_timeout=1495
DNS latency info:
vfid=0 server=2001::1 latency=1494 updated=73311
vfid=0 server=96.45.46.46 latency=1405 updated=2547
vfid=0 server=8.8.8.8 latency=19 updated=91
SDNS latency info:
vfid=0 server=173.243.140.53 latency=1 updated=707681
DNS_CACHE: alloc=35, hit=26
RATING_CACHE: alloc=1, hit=49
DNS UDP: req=66769 res=63438 fwd=83526 alloc=0 cmp=0 retrans=16855 to=3233
         cur=111 switched=8823467 num_switched=294 v6_cur=80 v6_switched=7689041 num_v6_
```

```

switched=6
      ftg_res=8 ftg_fwd=8 ftg_retrans=0
DNS TCP: req=0, res=0, fwd=0, retrans=0 alloc=0, to=0
FQDN: alloc=45 nl_write_cnt=9498 nl_send_cnt=21606 nl_cur_cnt=0
Botnet: searched=57 hit=0 filtered=57 false_positive=0

```

To view the latency from web filter and outbreak protection servers using the CLI:

```

# diagnose debug rating
Locale   : english

```

```

Service  : Web-filter
Status   : Enable
License  : Contract

```

```

Service  : Antispam
Status   : Disable

```

```

Service  : Virus Outbreak Prevention
Status   : Disable

```

```

DNS over TLS and HTTPS

DNS over TLS (DoT) is a security protocol for encrypting and encapsulating DNS queries and responses over the TLS protocol. DoT increases user privacy and security by preventing eavesdropping and manipulation of DNS data via man-in-the-middle attacks. Similarly, DNS over HTTPS (DoH) provides a method of performing DNS resolution over a secure HTTPS connection. DoT and DoH are supported in explicit mode where the FortiGate acts as an explicit DNS server that listens for DoT and DoH requests. Local-out DNS traffic over TLS and HTTPS is also supported.

Basic configurations for enabling DoT and DoH for local-out DNS queries

Before enabling DoT or DoH, ensure that they are supported by the DNS servers. The legacy FortiGuard DNS servers (208.91.112.53 and 208.91.112.52) do not support DoT or DoH queries, and will drop these packets. At times, the latency status of the DNS servers might also appear high or unreachable.

Disabling DoT and DoH is recommended when they are not supported by the DNS servers.

To enable DoT and DoH DNS in the GUI:

1. Go to *Network > DNS*.
2. Enter the primary and secondary DNS server addresses.

3. In the *DNS Protocols* section, enable *TLS (TCP/853)* and *HTTPS (TCP/443)*.

DNS Settings

DNS servers

Use FortiGuard Servers **Specify**

Video Tutorials

Apply

4. Configure the other settings as needed.
5. Click *Apply*.

To enable DoT and DoH DNS in the CLI:

```
config system dns
    set primary 1.1.1.1
    set secondary 1.0.0.1
    set protocol {cleartext dot doh}
end
```

To enable DoH on the DNS server in the GUI:

1. Go to *Network > DNS Servers*.
2. In the *DNS Service on Interface* section, edit an existing interface, or create a new one.
3. Select a *Mode*, and *DNS Filter* profile.
4. Enable *DNS over HTTPS*.

Edit DNS Service

Interface: port1

Mode: Recursive Non-Recursive Forward to System DNS

DNS Filter: ☒ dnsfilter

DNS over HTTPS: ☒

OK **Cancel**

5. Click *OK*.

To enable DoH on the DNS server in the CLI:

```
config system dns-server
    edit "port1"
        set dnsfilter-profile "dnsfilter"
```

```

    set doh enable
  next
end

```

Examples

The following examples demonstrate how to configure DNS settings to support DoT and DoH queries made to the FortiGate.

DoT

The following example uses a DNS filter profile where the education category is blocked.

To enable scanning DoT traffic in explicit mode with a DNS filter:

1. Configure the DNS settings:

```

config system dns
  set primary 1.1.1.1
  set secondary 1.0.0.1
  set protocol dot
end

```

2. Configure the DNS filter profile:

```

config dnsfilter profile
  edit "dnsfilter"
    config ftgd-dns
      config filters
        edit 1
          set category 30
          set action block
        next
      end
    end
  next
end

```

3. Configure the DNS server settings:

```

config system dns-server
  edit "port1"
    set dnsfilter-profile "dnsfilter"
  next
end

```

4. Send a DNS query over TLS (this example uses kdig on an Ubuntu client) using the FortiGate as the DNS server. The www.ubc.ca domain belongs to the education category:

```

root@client:/tmp# kdig -d @10.1.100.173 +tls +header +all www.ubc.ca
;; DEBUG: Querying for owner(www.ubc.ca.), class(1), type(1), server(10.1.100.173), port
(853), protocol(TCP)
;; DEBUG: TLS, received certificate hierarchy:
;; DEBUG: #1,
C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=FortiGate,CN=FG3H1E5818903681,EMAIL=support
@fortinet.com
;; DEBUG:      SHA-256 PIN: XhkpV9ABEhxDLtWG+lGEndNrBR7BlxjRYlGn2ltlkb8=
;; DEBUG: #2, C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=Certificate
Authority,CN=fortinet-subca2001,EMAIL=support@fortinet.com
;; DEBUG:      SHA-256 PIN: 3T8EqFBjpRSkxQNPFagjUNeEUghXOEYp904ROlJM8yo=
;; DEBUG: #3, C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=Certificate
Authority,CN=fortinet-ca2,EMAIL=support@fortinet.com
;; DEBUG:      SHA-256 PIN: /QfV4N3k5oxQR5RHtW/rbn/HrHgKpMLN0DEaeXY5yPg=
;; DEBUG: TLS, skipping certificate PIN check
;; DEBUG: TLS, skipping certificate verification
;; TLS session (TLS1.2)-(ECDHE-RSA-SECP256R1)-(AES-256-GCM)
;; ->>HEADER<<- opcode: QUERY; status: NOERROR; id: 56719
;; Flags: qr rd; QUERY: 1; ANSWER: 1; AUTHORITY: 0; ADDITIONAL: 0

;; QUESTION SECTION:
;; www.ubc.ca.                IN      A

;; ANSWER SECTION:
www.ubc.ca.                60      IN      A          208.91.112.55

;; Received 44 B
;; Time 2021-03-12 23:11:27 PST
;; From 10.1.100.173@853(TCP) in 0.2 ms
root@client:/tmp#

```

The IP returned by the FortiGate for ubc.ca belongs to the FortiGuard block page, so the query was blocked successfully.

DoH

The following example uses a DNS filter profile where the education category is blocked.

To configure scanning DoH traffic in explicit mode with a DNS filter:

1. Configure the DNS settings:

```

config system dns
    set primary 1.1.1.1
    set secondary 1.0.0.1
    set protocol doh
end

```

2. Configure the DNS filter profile:

```

config dnsfilter profile
    edit "dnsfilter"
        config ftgd-dns
            config filters
                edit 1
                    set category 30
                    set action block
            end
        end
    end
end

```

```

        next
    end
end
next
end

```

3. Configure the DNS server settings:

```

config system dns-server
    edit "port1"
        set dnsfilter-profile "dnsfilter"
        set doh enable
    next
end

```

4. In your browser, enable DNS over HTTPS.

5. On your computer, edit the TCP/IP settings to use the FortiGate interface address as the DNS server.

6. In your browser, go to a website in the education category (www.ubc.ca). The website is redirected to the block page.

Transparent conditional DNS forwarder - NEW

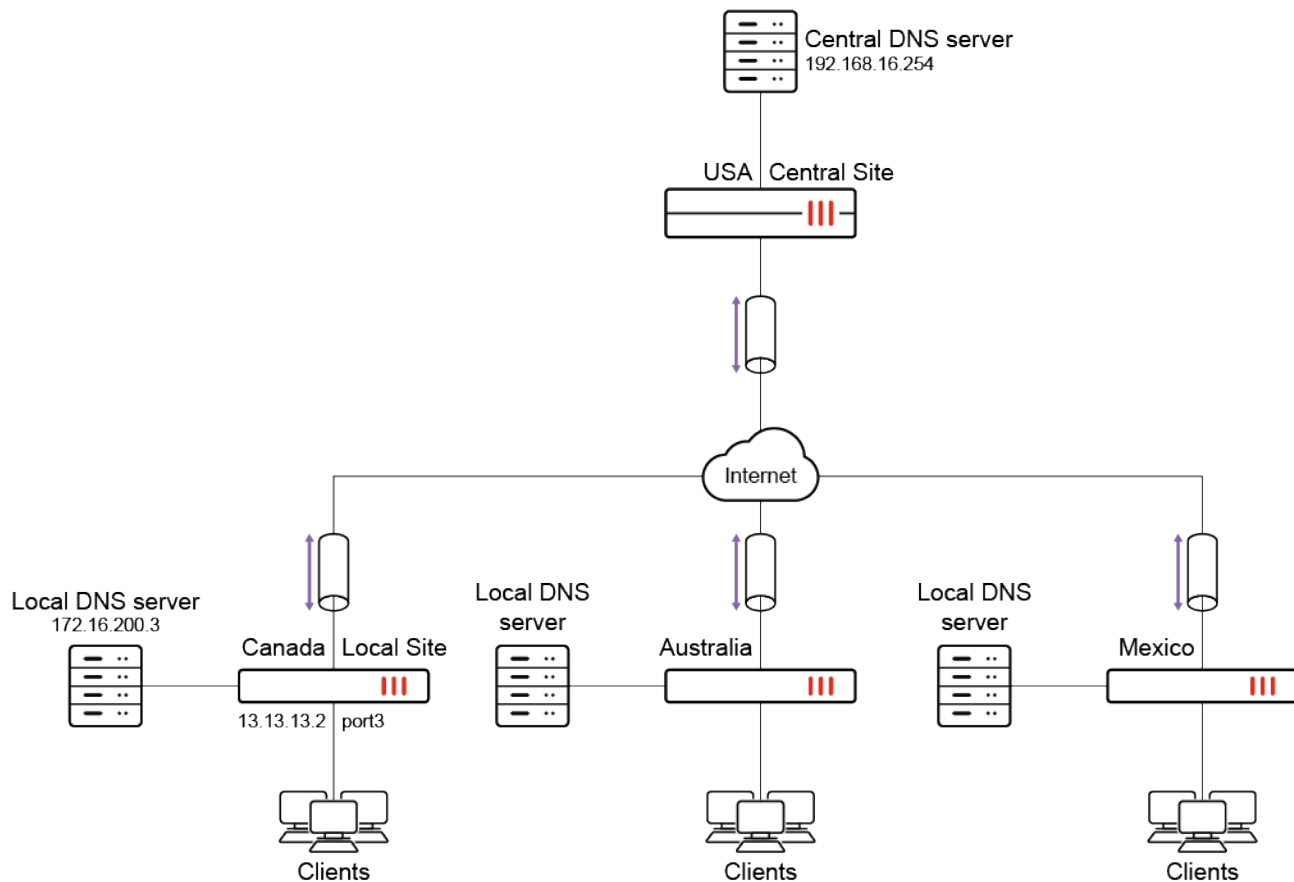

The transparent conditional DNS forwarder allows the FortiGate to intercept and reroute DNS queries for specific domains to a specific DNS server. For example, when a client's DNS is located in a distant location, in order to resolve destination addresses (such as SaaS applications) to the closest application server, the FortiGate can intercept and reroute the requests to a local DNS to resolve.

This is done by parsing entries and creating a list of filters based on the domain names of zones. When a DNS request matches one of these filters, the DNS proxy will retrieve the zone's data. The DNS request will then be handled based on the zone's forwarder settings and whether a local answer is available. It may be forwarded to the original destination address, the forwarder address, or not forwarded at all if a local answer is available.

This provides greater control over DNS requests, especially when the administrator is not managing the DNS server configuration of the client devices. This can improve network efficiency and performance by resolving IPs local to the client's PCs rather than IPs local to the central DNS server.

Example

In this example, FortiGates at various locations are connected to a central site by VPN tunnels where the corporate DNS server is located. Typically, DNS queries from different sites are sent to the central DNS server and resolved to an IP local to the central site, which might cause latency and performance issues for certain destinations, such as SaaS applications.

The Local Site FortiGate is configured with the Microsoft domain and a local DNS entry. Traffic matching the Microsoft domain is either forwarded to the local DNS server or resolved by the FortiGate, which resolves it to an IP local to the Local Site, thus improving performance.

This example assumes the following have been configured:

- A successfully operational site-to-site VPN between the Local Site and the Central Site FortiGates (see [Site-to-site VPN on page 1794](#) for more information).
- Appropriate routing and network interfaces.
- The client PCs are configured to use the Central DNS Server.

The transparent conditional DNS forwarder feature only works with a proxy-based firewall policy.

By default, DNS server options are not available in the GUI.

To enable DNS server options in the GUI:

1. Go to *System > Feature Visibility*.
2. In the *Additional Features* section, enable *DNS Database*.
3. Click *Apply*.

To configure the DNS zone and local DNS entries on the Local Site FortiGate in the GUI:

1. Go to *Network > DNS Servers*.
2. In the *DNS Database* table, click *Create New*.
3. Enter a *DNS Zone* name (*SaaS_applications*).
4. Enter a *Domain Name* (*microsoft.com*).
5. Disable the *Authoritative* setting.
6. In the *DNS Forwarder* field, click the + and enter the DNS Forwarder address (*172.16.200.3*).
7. Configure the DNS entry:
 - a. In the *DNS Entries* table, click *Create New*.
 - b. Set the *Type* to *Address (A)*.
 - c. Enter a *Hostname* (*office*).
 - d. Configure the remaining settings as needed. The options vary depending on the selected *Type*.
 - e. Click *OK*.
 - f. Optionally, add more DNS entries if needed.
8. In the CLI, configure the source IP:

```
config system dns-database
  edit "SaaS_applications"
    set source-ip 13.13.13.2
  next
end
```

If the DNS server is accessed over a VPN, it may be necessary to specify a source IP for the FortiGate to reach the DNS server. See [How to let the FortiGate access internal DNS through site-to-site IPsec VPN](#) for more information.

Site-to-site VPN is not a mandatory requirement for this feature to work and is only applicable to this example.

To configure the DNS zone and local DNS entries on the Local Site FortiGate in the CLI:

```
config system dns-database
  edit "SaaS_applications"
    set domain "microsoft.com"
    set authoritative disable
    set forwarder "172.16.200.3"
    set source-ip 13.13.13.2
    config dns-entry
      edit 1
        set hostname "office"
        set ip 172.16.200.55
      next
    end
```

```

    next
end

```

To add the DNS database to a DNS filter profile:

```

config dnsfilter profile
    edit "SaaS"
        set transparent-dns-database "SaaS_applications"
    next
end

```

Multiple DNS databases can be selected for `transparent-dns-database`.

After selecting a DNS database, users are not permitted to modify the domain name of the zone. Before making any changes to the domain name, remove the reference from the `dnsfilter` profile.

To apply the DNS filter profile in a firewall policy in the GUI:

1. Go to *Policy & Objects > Firewall Policy* and edit the outbound policy towards the IPsec VPN tunnel.
2. Set the *Inspection Mode* to *Proxy-based*.
3. In the *Security Profiles* section, enable *DNS Filter* and select the profile created in the previous procedure (*SaaS*).
4. In the *Logging Options* section, enable *Log Allowed Traffic*.
5. Configure the remaining settings as needed.
6. Click *OK*.

To apply the DNS filter profile to the outbound policy towards the IPsec VPN tunnel in the CLI:

```

config firewall policy
    edit 1
        set name "outbound_VPN"
        ...
        set inspection-mode proxy
        set dnsfilter-profile "SaaS"
        set logtraffic enable
        ...
    next
end

```

To verify the configuration:

From one of the Windows client desktops, use the `nslookup` command to send various DNS queries.

1. Send a DNS query for a DNS entry configured locally on the Local Site FortiGate:

```

C:\Users\demo>nslookup office.microsoft.com
Server:    Unknown
Address:   192.168.16.254
Non-authoritative answer:
Name:      osiprod-wus-pineapple-100.westus.cloudapp.azure.com
Address:   172.16.200.55

```

The query is resolved to the IP address configured on the Local Site FortiGate.

2. Send a DNS query for the domain configured on the Local Site FortiGate:

```
C:\Users\demo>nslookup teams.microsoft.com
Server:    Unknown
Address:   192.168.16.254
Non-authoritative answer:
Name:      s-0005.s-msedge.net
Address:   172.16.200.254
```

The query is resolved by the local DNS server.

3. Send a DNS query for a domain that is not configured on the Local Site FortiGate:

```
C:\Users\demo>nslookup facebook.com
Server:    Unknown
Address:   192.168.16.254
Non-authoritative answer:
Name:      facebook.com
Addresses: 157.240.249.35
```

The query is resolved by the central DNS server.

IPv6 support for conditional DNS forwarder

The configuration for IPv6 is similar to an IPv4 conditional DNS forwarder. When configuring the DNS forwarder address, the IPv6 address must be specified.

To configure a DNS forwarder:

```
config system dns-database
  edit <name>
    set source-ip6 <IPv6_address>
    set forwarder6 <IPv6_address>
  next
end
```

If the DNS server is accessed over a VPN, it may be necessary to specify a source IP for the FortiGate to reach the DNS server. See [How to let the FortiGate access internal DNS through site-to-site IPsec VPN](#) for more information.

DNS troubleshooting

The following diagnose command can be used to collect DNS debug information. If you do not specify worker ID, the default worker ID is 0.

```
# diagnose test application dnsproxy
worker idx: 0
1. Clear DNS cache
2. Show stats
3. Dump DNS setting
4. Reload FQDN
5. Requery FQDN
6. Dump FQDN
7. Dump DNS cache
8. Dump DNS DB
9. Reload DNS DB
```

10. Dump secure DNS policy/profile
11. Dump Botnet domain
12. Reload Secure DNS setting
13. Show Hostname cache
14. Clear Hostname cache
15. Show SDNS rating cache
16. Clear SDNS rating cache
17. DNS debug bit mask
18. DNS debug obj mem
99. Restart dnsproxy worker

To view useful information about the ongoing DNS connection:

```
# diagnose test application dnsproxy 3
worker idx: 0
vdom: root, index=0, is primary, vdom dns is disabled, mip-169.254.0.1 dns_log=1 tls=0 cert=
dns64 is disabled
vdom: vdom1, index=1, is primary, vdom dns is enabled, mip-169.254.0.1 dns_log=1 tls=0 cert=

FDG_SERVER:96.45.45.220:45
FGD_CATEGORY_VERSION:8
SERVER_LDB: gid=eb19, tz=-480, error_allow=0
FGD_REDIR_V4:208.91.112.55 FGD_REDIR_V6:
```

Important fields include:

tls	1 if the connection is TLS, 0 if the connection is not TLS.
rt	The round trip time of the DNS latency.
probe	The number of probes sent.

To dump the second DNS worker's cache:

```
# diagnose test application dnsproxy 7 1
```

To enable debug on the second worker:

```
# diagnose debug application dnsproxy -1 1
```

To enable debug on all workers by specifying -1 as worker ID:

```
# diagnose debug application dnsproxy -1 -1
```

Explicit and transparent proxies

This section contains instructions for configuring explicit and transparent proxies.

Explicit web proxy

Explicit web proxy can be configured on FortiGate for proxying HTTP and HTTPS traffic.

To deploy explicit proxy, individual client browsers can be manually configured to send requests directly to the proxy, or they can be configured to download proxy configuration instructions from a Proxy Auto-Configuration (PAC) file.

When explicit proxy is configured on an interface, the interface IP address can be used by client browsers to forward requests directly to the FortiGate. FortiGate also supports PAC file configuration.

To configure explicit web proxy in the GUI:

1. Enable and configure explicit web proxy:
 - a. Go to *Network > Explicit Proxy*.
 - b. Enable *Explicit Web Proxy*.
 - c. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *8080*.
 - d. Configure the remaining settings as needed.

- e. Click *Apply*.
2. Create an explicit web proxy policy:
 - a. Go to *Policy & Objects > Proxy Policy*.
 - b. Click *Create New*.
 - c. Set *Proxy Type* to *Explicit Web* and *Outgoing Interface* to *port1*.
 - d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.

- e. Click **OK** to create the policy.

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. Configure a client to use the FortiGate explicit proxy:

Set the FortiGate IP address as the proxy IP address in the browser, or use an automatic configuration script for the PAC file.

To configure explicit web proxy in the CLI:

1. Enable and configure explicit web proxy:

```
config web-proxy explicit
  set status enable
  set ftp-over-http enable
  set socks enable
  set http-incoming-port 8080
  set ipv6-status enable
  set unknown-http-version best-effort
end
config system interface
  edit "port2"
    set vdom "vdom1"
    set ip 10.1.100.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet
    set type physical
    set explicit-web-proxy enable
    set snmp-index 12
  end
next
end
```

2. Create an explicit web proxy policy:

```
config firewall proxy-policy
  edit 1
    set name "proxy-policy-explicit"
    set proxy explicit-web
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set logtraffic all
  next
end
```

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. Configure a client to use the FortiGate explicit web proxy:

Set the FortiGate IP address as the proxy IP address in the browser, or use an automatic configuration script for the PAC file.

Downloading a PAC file using HTTPS

PAC files can be downloaded for an explicit proxy through the FortiGate's captive portal using HTTPS to ensure a secure download.

In this example, a Windows PC has an HTTPS URL configured in its proxy settings to download a PAC file from a FortiGate by using a download link, <https://cp.myqalab.local:7831/proxy.pac>, through a captive portal. Once the PAC file is securely downloaded using HTTPS, browsers installed on the PC can use the proxy in the PAC file to visit a website.

The global web proxy settings must be configured to use a customized SSL certificate because the default Fortinet_Factory certificate will not be accepted by Windows due to security restrictions. The customized SSL certificate is used as the HTTPS server's certificate on the FortiGate. All CA certificates in the server certificate must be installed and trusted on the Windows PC.

To download a PAC file using HTTPS:**1. Configure the explicit web proxy to get a PAC file through HTTPS:**

```
config web-proxy explicit
  set pac-file-server-status enable
  unset pac-file-server-port
  set pac-file-name "proxy.pac"
  set pac-file-data "function FindProxyForURL(url, host) {
    // testtest
    return \"PROXY 10.1.100.1:8080\";
  }
  set pac-file-through-https enable
end
```

2. Configure the captive portal to be used as an HTTPS server to provide the service to download the PAC file:

```
config authentication setting
    set captive-portal-type ip
    set captive-portal-ip 10.1.100.1
    set captive-portal-ssl-port 7831
end
```

3. Configure the global web proxy settings to use a customized SSL certificate:

```
config web-proxy global
    set ssl-cert "server_cert"
end
```

4. On the Windows PC, go to *Settings > Network & Internet > Proxy*.

5. In the *Automatic proxy setup* section, click *Save* to trigger the PAC file download from the HTTPS URL.

FTP proxy

FTP proxies can be configured on the FortiGate so that FTP traffic can be proxied. When the FortiGate is configured as an FTP proxy, FTP client applications should be configured to send FTP requests to the FortiGate.

To configure explicit FTP proxy in the GUI:

1. Enable and configure explicit FTP proxy:
 - a. Go to *Network > Explicit Proxy*.
 - b. Enable *Explicit FTP Proxy*.
 - c. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *21*.
 - d. Configure the *Default Firewall Policy Action* as needed.

e. Click *Apply*.

2. Create an explicit FTP proxy policy:

- a. Go to *Policy & Objects > Proxy Policy*.
- b. Click *Create New*.
- c. Set *Proxy Type* to *FTP* and *Outgoing Interface* to *port1*.
- d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, and *Action* to *ACCEPT*.

e. Click *OK* to create the policy.

This example creates a basic policy. If required, security profiles can be enabled.

3. Configure the FTP client application to use the FortiGate IP address.

To configure explicit FTP proxy in the CLI:

1. Enable and configure explicit FTP proxy:

```
config ftp-proxy explicit
    set status enable
    set incoming-port 21
end
config system interface
    edit "port2"
        set vdom "vdom1"
        set ip 10.1.100.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set explicit-ftp-proxy enable
```

```

        set snmp-index 12
    next
end

```

2. Create an explicit FTP proxy policy:

```

config firewall proxy-policy
    edit 4
        set name "proxy-policy-ftp"
        set proxy ftp
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
    next
end

```

This example creates a basic policy. If required, security profiles can be enabled.

3. Configure the FTP client application to use the FortiGate IP address.

Changing the FTP mode from active to passive for explicit proxy

An explicit FTP proxy can convert an active FTP connection initiated by an FTP client to a passive FTP connection between the explicit FTP proxy and FTP server.

```

config ftp-proxy explicit
    set server-data-mode {client | passive}
end

```

```

server-data-mode {client
| passive}

```

Set the data selection mode on the FTP server side:

- **client:** use the same transmission mode for client and server data sessions (default).
- **passive:** use passive mode for server data sessions.

In this example, a client that only supports active mode FTP connects to a remote FTP server through the explicit FTP proxy to download a text file (test1.txt). The explicit FTP proxy converts the active FTP connection to a passive connection between the explicit FTP proxy and the FTP server.

To configure passive mode for FTP server data sessions:

1. Configure the web proxy:

```

config ftp-proxy explicit
    set status enable

```

```

        set incoming-port 21
        set server-data-mode passive
    end
end

```

2. Enable the explicit FTP proxy on port1:

```

config system interface
    edit "port1"
        set ip 10.1.100.2 255.255.255.0
        set explicit-ftp-proxy enable
    next
end

```

3. Configure the firewall policy:

```

config firewall proxy-policy
    edit 1
        set proxy ftp
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
    next
end

```

4. Get the client to download the text file from the FTP server (NcFTP is used in this example):

```

ncftpget -E -r 0 -d stdout -u pc4user1@172.16.200.44 -p 123456 10.1.100.2 ./
/home/pc4user1/test1.txt
...
Cmd: PORT 10,1,100,11,151,115
200: PORT command successful. Consider using PASV.
Cmd: RETR /home/pc4user1/test1.txt

```

5. In the FTP server logs, verify that the explicit FTP proxy converted the active FTP connection to a passive connection:

```

...

```

Transparent proxy

In a transparent proxy deployment, the user's client software, such as a browser, is unaware that it is communicating with a proxy.

Users request internet content as usual, without any special client configuration, and the proxy serves their requests. FortiGate also allows users to configure in transparent proxy mode.

To redirect HTTPS traffic, SSL inspection is required.

If the base firewall policy successfully redirects to the proxy policy then antivirus and web filter profiles configured on the firewall policy will not be applied. Security profiles should be configured on the proxy policy.

To configure transparent proxy in the GUI:

1. Configure a regular firewall policy with HTTP redirect:
 - a. Go to *Policy & Objects > Firewall Policy*.
 - b. Click *Create New*.
 - c. Name the policy appropriately, set the *Incoming Interface* to *port2*, and set the *Outgoing Interface* to *port1*.
 - d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, *Service* to *ALL*, and *Action* to *ACCEPT*.
 - e. Set *Inspection Mode* to *Proxy-based* and *SSL Inspection* to *deep-inspection*.

- f. Configure the remaining settings as needed.
- g. Click *OK*.

By default, HTTP redirect can only be enabled in the CLI. Enable *Policy Advanced Options* in *Feature Visibility* to configure it in the GUI. See [Feature visibility on page 2702](#) on page 1 for more information.

2. Configure a transparent proxy policy:

- a. Go to *Policy & Objects > Proxy Policy*.
- b. Click *Create New*.
- c. Set *Proxy Type* to *Transparent Web*, set the *Incoming Interface* to *port2*, and set the *Outgoing Interface* to *port1*.
- d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.

- e. Configure the remaining settings as needed.
- f. Click *OK* to create the policy.

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. No special configuration is required on the client to use FortiGate transparent proxy. As the client is using the FortiGate as its default gateway, requests will first hit the regular firewall policy, and then be redirected to the transparent proxy policy.

To configure transparent proxy in the CLI:

1. Configure a regular firewall policy with HTTP redirect:

```
config firewall policy
edit 1
    set name "LAN To WAN"
    set srcintf "port2"
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set inspection-mode proxy
```

```
        set http-policy-redirect enable
        set fsso disable
        set ssl-ssh-profile "deep-inspection"
        set nat enable
    next
end
```

2. Configure a transparent proxy policy:

```
config firewall proxy-policy
    edit 5
        set name "proxy-policy-transparent"
        set proxy transparent-web
        set srcintf "port2"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
    next
end
```

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. No special configuration is required on the client to use FortiGate transparent proxy. As the client is using the FortiGate as its default gateway, requests will first hit the regular firewall policy, and then be redirected to the transparent proxy policy.

Proxy policy addresses

Proxy addresses are designed to be used only by proxy policies. The following address types are available:

- [Host regex match on page 303](#)
- [URL pattern on page 303](#)
- [URL category on page 304](#)
- [HTTP method on page 305](#)
- [HTTP header on page 306](#)
- [User agent on page 306](#)
- [Advanced \(source\) on page 307](#)
- [Advanced \(destination\) on page 308](#)

Fast policy match

The fast policy match function improves the performance of IPv4 explicit and transparent web proxies on FortiGate devices.

When enabled, after the proxy policies are configured, the FortiGate builds a fast searching table based on the different proxy policy matching criteria. When fast policy matching is disabled, web proxy traffic is compared to the policies one at a time from the beginning of the policy list.

Fast policy matching is enabled by default, and can be configured with the following CLI command:

```
config web-proxy global
    set fast-policy-match {enable | disable}
end
```

Host regex match

In this address type, a user can create a hostname as a regular expression. Once created, the hostname address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the regular expression.

This example creates a host regex match address with the pattern `qa.[a-z]*.com`.

To create a host regex match address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *Host Regex*,
 - *Type* to *Host Regex Match*, and
 - *Host Regex Pattern* to `qa.[a-z]*.com`.

4. Click **OK**.

To create a host regex match address in the CLI:

```
config firewall proxy-address
    edit "Host Regex"
        set type host-regex
        set host-regex "qa.[a-z]*.com"
    next
end
```

URL pattern

In this address type, a user can create a URL path as a regular expression. Once created, the path address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the

regular expression.

This example creates a URL pattern address with the pattern `/filetypes/`.

To create a URL pattern address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *URL Regex*,
 - *Type* to *URL Pattern*,
 - *Host* to *all*, and
 - *URL Path Regex* to */filetypes/*.

4. Click *OK*.

To create a URL pattern address in the CLI:

```
config firewall proxy-address
  edit "URL Regex"
    set type url
    set host "all"
    set path "/filetypes/"
  next
end
```

URL category

In this address type, a user can create a URL category based on a FortiGuard URL ID. Once created, the address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the URL category.

The example creates a URL category address for URLs in the *Education* category. For more information about categories, see <https://fortiguard.com/webfilter/categories>.

For information about creating and using custom local and remote categories, see [Web rating override on page 1748](#), [Using local and remote categories on page 1756](#), and [Threat feeds on page 3099](#).

To create a URL category address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.

3. Set the following:

- *Category* to *Proxy Address*,
- *Name* to *url-category*,
- *Type* to *URL Category*,
- *Host* to *all*, and
- *URL Category* to *Education*.

4. Click **OK**.

To create a URL category address in the CLI:

```
config firewall proxy-address
  edit "url-category"
    set type category
    set host "all"
    set category 30
  next
end
```

To see a list of all the categories and their numbers, when editing the address, enter `set category ?`.

HTTP method

In this address type, a user can create an address based on the HTTP request methods that are used. Multiple method options are supported, including: *CONNECT*, *DELETE*, *GET*, *HEAD*, *OPTIONS*, *POST*, *PUT*, and *TRACE*. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests that match the selected HTTP method.

The example creates a HTTP method address that uses the GET method.

To create a HTTP method address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *method_get*,
 - *Type* to *HTTP Method*,
 - *Host* to *all*, and
 - *Request Method* to *GET*.
4. Click **OK**.

To create a HTTP method address in the CLI:

```
config firewall proxy-address
  edit "method_get"
    set type method
    set host "all"
    set method get
  next
end
```

HTTP header

In this address type, a user can create a HTTP header as a regular expression. Once created, the header address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests where the HTTP header matches the regular expression.

This example creates a HTTP header address with the pattern *Q[A-B]*.

To create a HTTP header address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *HTTP-header*,
 - *Type* to *HTTP Header*,
 - *Host* to *all*,
 - *Header Name* to *Header_Test*, and
 - *Header Regex* to *Q[A-B]*.
4. Click *OK*.

To create a HTTP header address in the CLI:

```
config firewall proxy-address
  edit "method_get"
    set type header
    set host "all"
    set header-name "Header_Test"
    set header "Q[A-B]"
  next
end
```

User agent

In this address type, a user can create an address based on the names of the browsers that are used as user agents. Multiple browsers are supported, such as Chrome, Firefox, Internet Explorer, and others. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests from the specified user agent.

This example creates a user agent address for Google Chrome.

To create a user agent address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *UA-Chrome*,
 - *Type* to *User Agent*,
 - *Host* to *all*, and
 - *User Agent* to *Google Chrome*.
4. Click *OK*.

To create a user agent address in the CLI:

```
config firewall proxy-address
  edit "UA-Chrome"
    set type ua
    set host "all"
    set ua chrome
  next
end
```

Browser version control

For security reasons, the user can restrict the browser version by specifying a range of the supported versions which can be set from the CLI using `set ua-min-ver` and `set ua-max-ver`. This option is available when the address *Type* is either *User Agent* or *Advanced (Source)*.

To restrict the browser version:

```
config firewall proxy-address
  edit "ua-ver"
    set type ua
    set ua firefox
    set ua-min-ver "100.0.1"
    set ua-max-ver "160"
  next
end
```

Advanced (source)

In this address type, a user can create an address based on multiple parameters, including HTTP method, User Agent, and HTTP header. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests that match the selected address.

This example creates an address that uses the get method, a user agent for Google Chrome, and an HTTP header with the pattern *Q[A-B]*.

To create an advanced (source) address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *advanced_src*,
 - *Type* to *Advanced (Source)*,
 - *Host* to *all*,
 - *Request Method* to *GET*,
 - *User Agent* to *Google Chrome*, and
 - *HTTP header* to *Header_Test : Q[A-B]*.
4. Click *OK*.

To create an advanced (source) address in the CLI:

```
config firewall proxy-address
  edit "advance_src"
    set type src-advanced
    set host "all"
    set method get
    set ua chrome
    config header-group
      edit 1
        set header-name "Header_Test"
        set header "Q[A-B]"
      next
    end
  next
end
```

Advanced (destination)

In this address type, a user can create an address based on URL pattern and URL category parameters. Once created, the address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the selected address.

This example creates an address with the URL pattern */about* that are in the *Education* category. For more information about categories, see <https://fortiguard.com/webfilter/categories>.

To create an advanced (destination) address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *Advanced-dst*,
 - *Type* to *Advanced (Destination)*,
 - *Host* to *all*,

- *URL Path Regex* to */about*, and
- *URL Category* to *Education*.

4. Click **OK**.

To create an advanced (destination) address in the CLI:

```
config firewall proxy-address
  edit "Advanced-dst"
    set type dst-advanced
    set host "ubc"
    set path "/about"
    set category 30
  next
end
```

Proxy policy security profiles

Web proxy policies support most security profile types.

Security profiles must be created before they can be used in a policy, see [Security Profiles on page 1425](#) for information.

Explicit web proxy policy

The security profiles supported by explicit web proxy policies are:

- *AntiVirus*
- *Web Filter*
- *Video Filter*
- *Application Control*
- *IPS*
- *DLP Profile*
- *ICAP*
- *Web Application Firewall*
- *File Filter*
- *SSL Inspection*

To configure security profiles on an explicit web proxy policy in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	Explicit Web
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	webproxy
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Web Filter	urlfilter
Application Control	app
IPS	Sensor-1
DLP Profile	dlp
ICAP	default
Web Application Firewall	default
SSL Inspection	deep-inspection

6. Click *OK* to create the policy.

To configure security profiles on an explicit web proxy policy in the CLI:

```
config firewall proxy-policy
edit 1
    set proxy explicit-web
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "web"
    set action accept
    set schedule "always"
    set utm-status enable
    set av-profile "av"
    set webfilter-profile "urlfilter"
    set dlp-profile "dlp"
    set ips-sensor "sensor-1"
```

```

        set application-list "app"
        set icap-profile "default"
        set waf-profile "default"
        set ssl-ssh-profile "deep-inspection"
    next
end

```

Transparent proxy

The security profiles supported by transparent proxy policies are:

- *AntiVirus*
- *Web Filter*
- *Video Filter*
- *Application Control*
- *IPS*
- *DLP Profile*
- *ICAP*
- *Web Application Firewall*
- *File Filter*
- *SSL Inspection*

To configure security profiles on a transparent proxy policy in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	Transparent Web
Incoming Interface	port2
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	webproxy
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Web Filter	urlfilter
Application Control	app

IPS	Sensor-1
DLP Profile	dlp
ICAP	default
Web Application Firewall	default
SSL Inspection	deep-inspection

6. Click **OK** to create the policy.

To configure security profiles on a transparent proxy policy in the CLI:

```
config firewall proxy-policy
  edit 2
    set proxy transparent-web
    set srcintf "port2"
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set utm-status enable
    set av-profile "av"
    set webfilter-profile "urlfilter"
    set dlp-profile "dlp"
    set ips-sensor "sensor-1"
    set application-list "app"
    set icap-profile "default"
    set waf-profile "default"
    set ssl-ssh-profile "certificate-inspection"
  next
end
```

FTP proxy

The security profiles supported by FTP proxy policies are:

- *AntiVirus*
- *Application Control*
- *IPS*
- *File Filter*
- *DLP Profile*

To configure security profiles on an FTP proxy policy in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	FTP
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to default.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Application Control	app
IPS	Sensor-1
DLP Profile	dlp

6. Click **OK** to create the policy.

To configure security profiles on an FTP proxy policy in the CLI:

```
config firewall proxy-policy
edit 3
    set proxy ftp
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set utm-status enable
    set av-profile "av"
    set dlp-profile "dlp"
    set ips-sensor "sensor-1"
    set application-list "app"
next
end
```

Explicit proxy authentication

FortiGate supports multiple authentication methods. This topic explains using an external authentication server with Kerberos as the primary and NTLM as the fallback.

To configure Explicit Proxy with authentication:

1. [Enable and configure the explicit proxy on page 314.](#)
2. [Configure the authentication server and create user groups on page 314.](#)
3. [Create an authentication scheme and rules on page 317.](#)

4. Create an explicit proxy policy and assign a user group to the policy on page 318.
5. Verify the configuration on page 318.

Enable and configure the explicit proxy

To enable and configure explicit web proxy in the GUI:

1. Go to *Network > Explicit Proxy*.
2. Enable *Explicit Web Proxy*.
3. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *8080*.
4. Configure the remaining settings as needed.
5. Click *Apply*.

To enable and configure explicit web proxy in the CLI:

```
config web-proxy explicit
    set status enable
    set ftp-over-http enable
    set socks enable
    set http-incoming-port 8080
    set ipv6-status enable
    set unknown-http-version best-effort
end
config system interface
    edit "port2"
        set vdom "vdom1"
        set ip 10.1.100.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set explicit-web-proxy enable
        set snmp-index 12
    end
next
end
```

Configure the authentication server and create user groups

Since we are using an external authentication server with Kerberos authentication as the primary and NTLM as the fallback, Kerberos authentication is configured first and then FSSO NTLM authentication is configured.

For successful authorization, the FortiGate checks if user belongs to one of the groups that is permitted in the security policy.

When configuring an LDAP connection to an Active Directory server, an administrator must provide Active Directory user credentials.

- To secure this connection, use LDAPS on both the Active Directory server and FortiGate. See [Configuring an LDAP server on page 2242](#) and [Configuring client certificate authentication on the LDAP server on page 2256](#).
- Apply the principle of least privilege. For the LDAP regular bind operation, do not use credentials that provide full administrative access to the Windows server when using credentials. See [Configuring least privileges for LDAP admin account authentication in Active Directory on page 2249](#).

To configure an authentication server and create user groups in the GUI:

1. Configure Kerberos authentication:

- Go to *User & Authentication > LDAP Servers*.
- Click *Create New*.
- Set the following:

Name	ldap-kerberos
Server IP	172.18.62.220
Server Port	389
Common Name Identifier	cn
Distinguished Name	dc=fortinetqa,dc=local

- Click *OK*

2. Define Kerberos as an authentication service. This option is only available in the CLI. For information on generating a keytab, see [Generating a keytab on a Windows server on page 319](#).

3. Configure FSSO NTLM authentication:

FSSO NTLM authentication is supported in a Windows AD network. FSSO can also provide NTLM authentication service to the FortiGate unit. When a user makes a request that requires authentication, the FortiGate initiates NTLM negotiation with the client browser, but does not process the NTLM packets itself. Instead, it forwards all the NTLM packets to the FSSO service for processing.

- Go to *Security Fabric > External Connectors*.
- Click *Create New* and select *FSSO Agent on Windows AD* from the *Endpoint/Identity* category.
- Set the *Name* to *FSSO*, *Primary FSSO Agent* to *172.16.200.220*, and enter a password.
- Click *OK*.

4. Create a user group for Kerberos authentication:

- Go to *User & Authentication > User Groups*.
- Click *Create New*.
- Set the *Name* to *Ldap-Group*, and *Type* to *Firewall*.
- In the *Remote Groups* table, click *Add*, and set the *Remote Server* to the previously created *ldap-kerberos* server.
- Click *OK*.

5. Create a user group for NTLM authentication:

- a. Go to *User & Authentication > User Groups*.
- b. Click *Create New*.
- c. Set the *Name* to *NTLM-FSSO-Group*, *Type* to *Fortinet Single Sign-On (FSSO)*, and add *FORTINETQA/FSSO* as a member.
- d. Click *OK*.

To configure an authentication server and create user groups in the CLI:

1. Configure Kerberos authentication:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.220"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *****
    next
end
```

2. Define Kerberos as an authentication service:

```
config user krb-keytab
    edit "http_service"
        set pac-data disable
        set principal "HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL"
        set ldap-server "ldap-kerberos"
        set keytab
        "BQIAAABFAAIAEEZPULRJTkVUUUEuTE9DQUwABehUVFAAFEZHVC5GT1JUSU5FVFFBLkxPQ0FMAAAAAQAAAAEAAE
        ACKLCMonpitnVAAAAARQACABBGt1JUSU5FVFFBLkxPQ0FMAARIVFRQABRGR1QuRk9SVElORVRRQS5MT0NBTA AAAAE
        AAAAAABAADAAiiwJKJ6YrZlQAAAE0AAgAQrk9SVElORVRRQS5MT0NBTA AESFRUUA AURkdULkZPULRJTkVUUUEuTE9
        DQUwAAAAABAAAAAQAFwAQUHo9uqR9cSkzyxdzKCEXdwAAAF0AAgAQrk9SVElORVRRQS5MT0NBTA AESFRUUA AURkd
        ULkZPULRJTkVUUUEuTE9DQUwAAAAABAAAAAQAEgAgzee854Aq1HhQiKJZvV4tL2Poy7hMIARQpK8MCB//BIAAAB
        NAAIAEEZPULRJTkVUUUEuTE9DQUwABehUVFAAFEZHVC5GT1JUSU5FVFFBLkxPQ0FMAAAAAQAAAAEABEAEG49vHE
        iiBghr63Z/lnwYrU="
    next
end
```

For information on generating a keytab, see [Generating a keytab on a Windows server on page 319](#).

3. Configure FSSO NTLM authentication:

```
config user fsso
    edit "1"
        set server "172.18.62.220"
        set password *****
    next
end
```

4. Create a user group for Kerberos authentication:

```
config user group
    edit "Ldap-Group"
        set member "ldap" "ldap-kerberos"
    next
end
```

5. Create a user group for NTLM authentication:

```
config user group
    edit "NTLM-FSSO-Group"
        set group-type fsso-service
        set member "FORTINETQA/FSSO"
    next
end
```

Create an authentication scheme and rules

Explicit proxy authentication is managed by authentication schemes and rules. An authentication scheme must be created first, and then the authentication rule.

To create an authentication scheme and rules in the GUI:

1. Create an authentication scheme:
 - a. Go to *Policy & Objects > Authentication Rules*.
 - b. Click *Create New > Authentication Schemes*.
 - c. Set the *Name* to *Auth-scheme-Negotiate* and select *Negotiate* as the *Method*.
 - d. Click *OK*.
2. Create an authentication rule:
 - a. Go to *Policy & Objects > Authentication Rules*.
 - b. Click *Create New > Authentication Rules*.
 - c. Set the *Name* to *Auth-Rule*, *Source Address* to *all*, and *Protocol* to *HTTP*.
 - d. Enable *Authentication Scheme*, and select the just created *Auth-scheme-Negotiate* scheme.
 - e. Click *OK*.

To create an authentication scheme and rules in the CLI:

1. Create an authentication scheme:

```
config authentication scheme
    edit "Auth-scheme-Negotiate"
        set method negotiate <<< Accepts both Kerberos and NTLM as fallback
    next
end
```

2. Create an authentication rule:

```
config authentication rule
    edit "Auth-Rule"
        set status enable
        set protocol http
        set srcaddr "all"
        set ip-based enable
        set active-auth-method "Auth-scheme-Negotiate"
        set comments "Testing"
    next
end
```

Create an explicit proxy policy and assign a user group to the policy

To create an explicit proxy policy and assign a user group to it in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Click *Create New*.
3. Set *Proxy Type* to *Explicit Web* and *Outgoing Interface* to *port1*.
4. Set *Source* to *all*, and the just created user groups *NTLM-FSSO-Group* and *Ldap-Group*.
5. Also set *Destination* to *all*, *Schedule* to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.
6. Click *OK*.

To create an explicit proxy policy and assign a user group to it in the CLI:

```
config firewall proxy-policy
  edit 1
    set proxy explicit-web
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "web"
    set action accept
    set schedule "always"
    set logtraffic all
    set groups "NTLM-FSSO-Group" "Ldap-Group"
    set av-profile "av"
    set ssl-ssh-profile "deep-custom"
  next
end
```

Verify the configuration

Log in using a domain and system that would be authenticated using the Kerberos server, then enter the `diagnose wad user list` CLI command to verify:

```
# diagnose wad user list
ID: 8, IP: 10.1.100.71, VDOM: vdom1
  user name      : test1@FORTINETQA.LOCAL
  duration       : 389
  auth_type      : IP
  auth_method    : Negotiate
  pol_id         : 1
  g_id           : 1
  user_based     : 0
  expire         : no
  LAN:
    bytes_in=4862 bytes_out=11893
  WAN:
    bytes_in=7844 bytes_out=1023
```

Log in using a system that is not part of the domain. The NTLM fallback server should be used:

```
# diagnose wad user list
ID: 2, IP: 10.1.100.202, VDOM: vdom1
```

```

user name      : TEST31@FORTINETQA
duration       : 7
auth_type      : IP
auth_method    : NTLM
pol_id         : 1
g_id           : 5
user_based     : 0
expire         : no
LAN:
  bytes_in=6156 bytes_out=16149
WAN:
  bytes_in=7618 bytes_out=1917

```

Generating a keytab on a Windows server

A keytab is used to allow services that are not running Windows to be configured with service instance accounts in the Active Directory Domain Service (AD DS). This allows Kerberos clients to authenticate to the service through Windows Key Distribution Centers (KDCs).

For an explanation of the process, see <https://docs.microsoft.com/en-us/windows-server/administration/windows-commands/ktpass>.

To generate a keytab on a Windows server:

1. On the server, create a user for the FortiGate:
 - The service name is the FQDN for the explicit proxy interface, such as the hostname in the client browser proxy configuration. In this example, the service name is *FGT*.
 - The account only requires *domain users* membership.
 - The password must be very strong.
 - The password is set to never expire.

2. Add the FortiGate FQDN in to the Windows DNS domain, as well as in-addr.arpa.

3. Generate the Kerberos keytab using the `ktpass` command on Windows servers and many domain workstations:

```
# ktpass -princ HTTP/<domain name of test fgt>@realm -mapuser <user> -pass <password> -
crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

For example:

```
ktpass -princ HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL -mapuser FGT -pass *****
-crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

If the FortiGate is handling multiple keytabs in Kerberos authentication, use different passwords when generating each keytab.

4. Encode the keytab to base64 in a text file:

- On Windows: `certutil -encode fgt.keytab tmp.b64 && findstr /v /c:- tmp.b64 > fgt.txt`
- On Linux: `base64 fgt.keytab > fgt.txt`
- On MacOS: `base64 -i fgt.keytab -o fgt.txt`

5. Use the code in `fgt.txt` as the keytab parameter when configuring the FortiGate.

Transparent web proxy forwarding

In FortiOS, there is an option to enable proxy forwarding for transparent web proxy policies and regular firewall policies for HTTP and HTTPS.

In previous versions of FortiOS, you could forward proxy traffic to another proxy server (proxy chaining) with explicit proxy. Now, you can forward web traffic to the upstream proxy without having to reconfigure your browsers or publish a proxy auto-reconfiguration (PAC) file.

Once configured, the FortiGate forwards traffic generated by a client to the upstream proxy. The upstream proxy then forwards it to the server.

To configure proxy forwarding:

1. Configure the web proxy forwarding server:

```
config web-proxy forward-server
  edit "upStream_proxy_1"
    set ip 172.16.200.20
    set healthcheck enable
    set monitor "http://www.google.ca"
  next
end
```

2. Append the web proxy forwarding server to a firewall policy:

```
config firewall policy
  edit 1
    set name "LAN To WAN"
    set srcintf "port10"
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set logtraffic all
    set webproxy-forward-server "upStream_proxy_1"
    set fsso disable
    set av-profile "av"
    set ssl-ssh-profile "deep-custom"
    set nat enable
  next
end
```

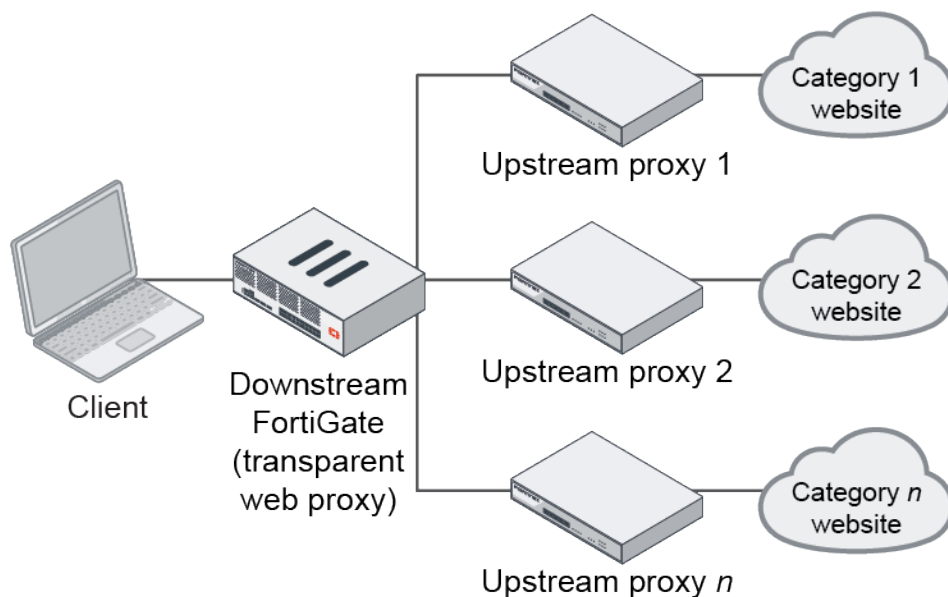

Selectively forward web requests to a transparent web proxy

Web traffic over HTTP/HTTPS can be forwarded selectively by the FortiGate's transparent web proxy to an upstream web proxy to avoid overwhelming the proxy server. Traffic can be selected by specifying the proxy address, which can be based on a FortiGuard URL category.

The FortiGuard web filter service must be enabled on the downstream FortiGate.

Topology

Forwarding behavior

The forward server will be ignored if the proxy policy matching for a particular session needs the FortiGate to see authentication information inside the HTTP (plain text) message. For example, assume that user authentication is required and a forward server is configured in the transparent web proxy, and the authentication method is an active method (such as basic). When the user or client sends the HTTP request over SSL with authentication information to the FortiGate, the request cannot be forwarded to the upstream proxy. Instead, it will be forwarded directly to the original web server (assuming deep inspection and `http-policy-redirect` are enabled in the firewall policy).

The FortiGate will close the session before the client request can be forwarded if all of the following conditions are met:

- The certificate inspection is configured in the firewall policy that has the `http-policy-redirect` option enabled.
- A previously authenticated IP-based user record cannot be found by the FortiGate's memory during the SSL handshake.
- Proxy policy matching needs the FortiGate to see the HTTP request authentication information.

This means that in order to enable user authentication and use `webproxy-forward-server` in the transparent web proxy policy at the same time, the following best practices should be followed:

- In the firewall policy that has the `http-policy-redirect` option enabled, set `ssl-ssh-profile` to use the `deep-inspection` profile.
- Use IP-based authentication rules; otherwise, the `webproxy-forward-server` setting in the transparent web proxy policy will be ignored.
- Use a passive authentication method such as FSSO. With FSSO, once the user is authenticated as a domain user by a successful login, the web traffic from the user's client will always be forwarded to the upstream proxy as long as the authenticated user remains unexpired. If the authentication method is an active authentication method (such as basic, digest, NTLM, negotiate, form, and so on), the first session containing authentication information will bypass the forward server, but the following sessions will be connected through the upstream proxy.

Sample configuration

On the downstream FortiGate proxy, there are two category proxy addresses used in two separate transparent web proxy policies as the destination address:

- In the policy with `upstream_proxy_1` as the forward server, the proxy address `category_infotech` is used to match URLs in the information technology category.
- In the policy with `upstream_proxy_2` as the forward server, the proxy address `category_social` is used to match URLs in the social media category.

To configure forwarding requests to transparent web proxies:

1. Configure the proxy forward servers:

```
config web-proxy forward-server
  edit "upStream_proxy_1"
    set ip 172.16.200.20
  next
  edit "upStream_proxy_2"
    set ip 172.16.200.46
  next
end
```

2. Configure the web proxy addresses:

```
config firewall proxy-address
  edit "category_infotech"
    set type category
    set host "all"
    set category 52
  next
  edit "category_social"
    set type category
    set host "all"
    set category 37
  next
end
```

3. Configure the firewall policy:

```
config firewall policy
  edit 1
    set srcintf "port10"
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set inspection-mode proxy
    set http-policy-redirect enable
    set ssl-ssh-profile "deep-inspection"
    set av-profile "av"
    set nat enable
  next
end
```

4. Configure the proxy policies:

```
config firewall proxy-policy
  edit 1
    set proxy transparent-web
    set srcintf "port10"
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "category_infotech"
    set service "webproxy"
    set action accept
    set schedule "always"
    set logtraffic all
    set webproxy-forward-server "upStream_proxy_1"
    set utm-status enable
    set ssl-ssh-profile "deep-inspection"
    set av-profile "av"
  next
  edit 2
    set proxy transparent-web
    set srcintf "port10"
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "category_social"
    set service "webproxy"
    set action accept
    set schedule "always"
    set logtraffic all
    set webproxy-forward-server "upStream_proxy_2"
    set utm-status enable
    set ssl-ssh-profile "deep-inspection"
    set av-profile "av"
  next
end
```

Upstream proxy authentication in transparent proxy mode

A downstream proxy FortiGate that needs to be authenticated by the upstream web proxy can use the basic authentication method to send its username and password, in the base64 format, to the upstream web proxy for authentication. If the authentication succeeds, web traffic that is forwarded from the downstream proxy FortiGate to the upstream proxy can be accepted and forwarded to its destinations.

In this example, a school has a FortiGate acting as a downstream proxy that is configured with firewall policies for each user group (students and staff). In each policy, a forwarding server is configured to forward the web traffic to the upstream web proxy.

The username and password that the upstream web proxy uses to authenticate the downstream proxy are configured on the forwarding server, and are sent to the upstream web proxy with the forwarded HTTP requests.

	Username	Password
student.proxy.local:8080	students	ABC123
staff.proxy.local:8081	staff	123456

On the downstream FortiGate, configure forwarding servers with the usernames and passwords for authentication on the upstream web proxy, then apply those servers to firewall policies for transparent proxy. For explicit web proxy, the forwarding servers can be applied to proxy policies.

When the transparent proxy is configured, clients can access websites without configuring a web proxy in their browser. The downstream proxy sends the username and password to the upstream proxy with forwarded HTTP requests to be authenticated.

To configure the forwarding server on the downstream FortiGate:

```
config web-proxy forward-server
  edit "Student_Upstream_WebProxy"
    set addr-type fqdn
    set fqdn "student.proxy.local"
    set port 8080
    set username "student"
    set password ABC123
  next
  edit "Staff_Upstream_WebProxy"
    set addr-type fqdn
    set fqdn "staff.proxy.local"
    set port 8081
    set username "staff"
    set password 123456
  next
end
```

To configure firewall policies for transparent proxy:

```
config firewall policy
  edit 1
    set srcintf "Vlan_Student"
    set dstintf "port9"
    set srcaddr "Student_Subnet"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set inspection-mode proxy
    set ssl-ssh-profile "deep-inspection"
    set av-profile "av"
    set webproxy-forward-server "Student_Upstream_WebProxy"
    set nat enable
  next
  edit 2
    set srcintf "Vlan_Staff"
    set dstintf "port9"
    set srcaddr "Staff_Subnet"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set inspection-mode proxy
    set ssl-ssh-profile "deep-inspection"
```

```

        set av-profile "av"
        set webproxy-forward-server "Staff_Upstream_WebProxy"
        set nat enable
    next
end

```

Multiple dynamic header count

Multiple dynamic headers are supported for web proxy profiles, as well as Base64 encoding and the append/new options.

Administrators only have to select the dynamic header in the profile. The FortiGate will automatically display the corresponding static value. For example, if the administrator selects the `$client-ip` header, the FortiGate will display the actual client IP address.

The supported headers are:

<code>\$client-ip</code>	Client IP address
<code>\$user</code>	Authentication user name
<code>\$domain</code>	User domain name
<code>\$local_grp</code>	Firewall group name
<code>\$remote_grp</code>	Group name from authentication server
<code>\$proxy_name</code>	Proxy realm name

To configure dynamic headers using the CLI:

Since authentication is required, FSSO NTLM authentication is configured in this example.

1. Configure LDAP:

```

config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.220"
        set cnid "cn=a"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *****
    next
end

```

2. Configure FSSO:

```

config user fsso
    edit "1"
        set server "172.18.62.220"
        set password *****
    next
end

```

3. Configure a user group:

```
config user group
  edit "NTLM-FSSO"
    set group-type fsso-service
    set member "FORTINETQA/FSSO"
  next
end
```

4. Configure an authentication scheme:

```
config authentication scheme
  edit "au-sch-ntlm"
    set method ntlm
  next
end
```

5. Configure an authentication rule:

```
config authentication rule
  edit "au-rule-fsso"
    set srcaddr "all"
    set active-auth-method "au-sch-ntlm"
  next
end
```

6. Create a web proxy profile that adds a new dynamic and custom Via header:

```
config web-proxy profile
  edit "test"
    set log-header-change enable
    config headers
      edit 1
        set name "client-ip"
        set content "$client-ip"
      next
      edit 2
        set name "Proxy-Name"
        set content "$proxy_name"
      next
      edit 3
        set name "user"
        set content "$user"
      next
      edit 4
        set name "domain"
        set content "$domain"
      next
      edit 5
        set name "local_grp"
        set content "$local_grp"
      next
      edit 6
        set name "remote_grp"
        set content "$remote_grp"
      next
      edit 7
        set name "Via"
        set content "Fortigate-Proxy"
      next
    end
  end
```

```

        end
    next
end

```

7. In the proxy policy, append the web proxy profile created in the previous step:

```

config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set logtraffic all
        set groups "NTLM-FSSO"
        set webproxy-profile "test"
        set utm-status enable
        set av-profile "av"
        set webfilter-profile "content"
        set ssl-ssh-profile "deep-custom"
    next
end

```

8. Once traffic is being generated from the client, look at the web filter logs to verify that it is working.

The corresponding values for all the added header fields are shown in the *Web Filter* card at *Log & Report > Security Events*, in the *Change headers* section at the bottom of the *Log Details* pane.

```

1: date=2019-02-07 time=13:57:24 logid="0344013632" type="utm" subtype="webfilter"
eventtype="http_header_change" level="notice" vd="vdom1" eventtime=1549576642 policyid=1

NTLM-FSSO|remote_grp: FORTINETQA/FSSO|Via: Fortigate-Proxy"

```

Restricted SaaS access

Large organizations may want to restrict SaaS access to resources like Microsoft Office 365, Google Workspace, and Dropbox by tenant to block non-company login attempts and secure the users from accessing non-approved cloud resources. Many cloud vendors enable this by applying tenant restrictions for access control. For example, users accessing Microsoft 365 applications with tenant restrictions through the corporate proxy will only be allowed to log in as the company's tenant and access the organization's applications.

To implement this, access requests from the clients pass through the company's web proxy, which inserts headers to notify the SaaS service to apply tenant restrictions with the permitted tenant list. Users are redirected the SaaS service login page, and are only allowed to log in if they belong to the permitted tenant list.

For more information, refer to the vendor-specific documentation:

- Office 365: [Restrict access to a tenant](#)
- Google Workspace: [Block access to consumer accounts](#)
- Dropbox: [Network control](#)

Basic configuration

A web proxy profile can specify access permissions for Microsoft Office 365, Google Workspace, and Dropbox by inserting vendor-defined headers that restrict access to the specific accounts. Custom headers can also be inserted for any destination. The web proxy profile can then be applied to a firewall policy to control the header's insertion.

To implement Office 365 tenant restriction, Google Workspace account access control, and Dropbox network access control:

1. Configure a web proxy profile according to the vendors' specifications:
 - a. Set the header name (defined by the service provider).
 - b. Set the traffic destination (the service provider).
 - c. Set the HTTP header content to be inserted into the traffic (defined by your settings).

```
config web-proxy profile
  edit <name>
    config headers
      edit <id>
        set name <string>
        set dstaddr <address>
        set action add-to-request
        set base64-encoding disable
        set add-option new
        set protocol https http
        set content <string>
      next
    end
  next
end
```

2. Apply the web proxy profile to a policy. SSL deep inspection must be used in the firewall policy:

The following table lists the vendor-specific `config headers` settings that must be configured in the web proxy profile (`config web-proxy profile`):

Setting	Vendor specification		
	Microsoft Office 365	Google Workspace	Dropbox
name <string>	<ul style="list-style-type: none"> Restrict-Access-To-Tenants Restrict-Access-Context 	<ul style="list-style-type: none"> X-GoogApps-Allowed-Domains 	<ul style="list-style-type: none"> X-Dropbox-allowed-Team-Ids
dstaddr <address>	<ul style="list-style-type: none"> Use the built-in Microsoft Office 365 address. 	<ul style="list-style-type: none"> Use the built-in G Suite address. 	<ul style="list-style-type: none"> Use the built-in wildcard.dropbox.com address.
content <string>	<ul style="list-style-type: none"> Enter the domain for Restrict-Access-To- 	<ul style="list-style-type: none"> Enter the domain. 	<ul style="list-style-type: none"> Enter the Dropbox team ID.

Setting	Vendor specification		
	Microsoft Office 365	Google Workspace	Dropbox
	Tenants. <ul style="list-style-type: none">• Enter the directory ID for Restrict-Access-Context.		

Due to vendors' changing requirements, these settings may no longer comply with the vendors' official guidelines. See the vendor documentation for more details.

Microsoft Office 365 example

In this example, a web proxy profile is created to control permissions for Microsoft Office 365 to allow corporate domains and deny personal accounts, such as Hotmail and Outlook that are accessed through login.live.com.

1. When a user attempts to access login.microsoftonline.com, login.microsoft.com, or login.windows.net, the traffic will match a proxy inspection mode firewall policy with the assigned web proxy profile.
2. The web proxy profile adds new headers to the customer tenant, indicating the allowed domain and restricted access for personal accounts. Next, the FortiGate starts a new connection with the Microsoft Office 365 domain controller including the new headers.
3. The Microsoft Office 365 domain controller assesses this data and will allow or deny this access, then sends a reply to the FortiGate.
4. The FortiGate sends a reply to the client.

The FortiGate will only indicate the correct domains to be allowed or denied through the headers to Microsoft. The custom sign-in portal in the browser is generated by Microsoft.

Configuration summary

The following must be configured in FortiOS:

- An FQDN address for login.live.com
- An SSL inspection profile that uses deep inspection with an exemption for login.live.com

Ensure that the firewall certificate is installed on the client machines. A company certificate signed by an internal CA is recommended.

- A web filter profile in proxy mode with static URL filters for the SNI URLs
- A web proxy profile that adds new headers to the customer tenant

- A firewall policy using proxy mode inspection that applies the configured SSL inspection, web filter, and web proxy profiles

The `Restrict-Access-To-Tenants` and `Restrict-Access-Context` headers are inserted for incoming requests to: `login.microsoftonline.com`, `login.microsoft.com`, and `login.windows.net`, which are part of the Microsoft Office 365 address group.

To restrict access to personal accounts using the `login.live.com` domain, the `sec-Restrict-Tenant-Access-Policy` header is inserted and uses `restrict-msa` as the header content.

Before configuring the FortiGate, collect the information related to the company domain in the Office 365 contract.

- `Restrict-Access-To-Tenants`: your <domain.com>
- `Restrict-Access-Context`: Directory ID

To find the Directory ID related to the domain, locate it in the Azure portal, or use the whatismytenantid.com open tool.

To configure the FortiGate:

1. Add the FQDN address for `login.live.com`:

```
config firewall address
    edit "login.live.com"
        set type fqdn
        set fqdn "login.live.com"
    next
end
```

2. Configure the SSL inspection profile. In this example, the `deep-inspection` profile is cloned, and the `live.com` FQDN is removed from the exemption list.

- a. Clone the `deep-inspection` profile:

```
config firewall ssl-ssh-profile
    clone "deep-inspection" to "Tenant"
end
```

- b. Edit the `Tenant` profile and remove `live.com` from the `config ssl-exempt` list.

3. Configure the URL filter list:

```
config webfilter urlfilter
    edit 1
        set name "Auto-webfilter-urlfilter"
        config entries
            edit 1
                set url "login.microsoftonline.com"
                set action allow
            next
            edit 2
                set url "login.microsoft.com"
                set action allow
            next
            edit 3
                set url "login.windows.net"
                set action allow
        next
    next
end
```

```

        next
        edit 4
            set url "login.live.com"
            set action allow
        next
    end
next
end

```

4. Configure the web filter profile:

```

config webfilter profile
    edit "Tenant"
        set comment "Office 365"
        set feature-set proxy
        config web
            set urlfilter-table 1
        end
    next
end

```

5. Configure the web proxy profile (enter the header names exactly as shown):

```

config web-proxy profile
    edit "SaaS-Tenant-Restriction"
        set header-client-ip pass
        set header-via-request pass
        set header-via-response pass
        set header-x-forwarded-for pass
        set header-x-forwarded-client-cert pass
        set header-front-end-https pass
        set header-x-authenticated-user pass
        set header-x-authenticated-groups pass
        set strip-encoding disable
        set log-header-change disable
        config headers
            edit 1
                set name "Restrict-Access-To-Tenants"
                set dstaddr "login.microsoft.com" "login.microsoftonline.com"
                "login.windows.net"
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content <domain>
            next
            edit 2
                set name "Restrict-Access-Context"
                set dstaddr "login.microsoftonline.com" "login.microsoft.com"
                "login.windows.net"
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content <directory_ID>
            next
            edit 3

```

```

        set name "sec-Restrict-Tenant-Access-Policy"
        set dstaddr "login.live.com"
        set action add-to-request
        set base64-encoding disable
        set add-option new
        set protocol https http
        set content "restrict-msa"
    next
end
next
end

```

6. Configure the firewall policy:

```

config firewall policy
    edit 10
        set name "Tenant"
        set srcintf "port2"
        set dstintf "port1"
        set action accept
        set srcaddr "users-lan"
        set dstaddr "login.microsoft.com" "login.microsoftonline.com"
        "login.windows.net" "login.live.com"
        set schedule "always"
        set service "HTTP" "HTTPS"
        set utm-status enable
        set inspection-mode proxy
        set webproxy-profile "SaaS-Tenant-Restriction"
        set ssl-ssh-profile "Tenant"
        set webfilter-profile "Tenant"
        set logtraffic all
        set nat enable
    next
end

```

Testing the access

To test the access to corporate domains and personal accounts:

1. Get a client to log in with their corporate email using the login.microsoftonline.com domain.

2. The client is able to enter their credentials and log in successfully.

3. Get a client to log in to their personal Outlook account.

4. After the client enters their credentials, a message appears that they cannot access this resource because it is restricted by the cross-tenant access policy.

Verifying the header insertion

To verify the header insertion for corporate domains and personal accounts:

1. On the FortiGate, start running the WAD debugs:

```
# diagnose wad debug enable category http
# diagnose wad debug enable level info
# diagnose debug enable
```

2. After a client attempts to access corporate domains, verify that the header information is sent to the Microsoft Active Directory:

```
[I][p:234][s:2481][r:33] wad_dump_fwd_http_req          :2567  hreq=0x7fc75f0cd468

Explicit proxy and FortiGate Cloud Sandbox

Explicit proxy connections can leverage FortiGate Cloud Sandbox for advanced threat scanning and updates. This allows FortiGates behind isolated networks to connect to FortiCloud services.

To configure FortiGuard services to communicate with an explicit proxy server:

```
config system fortiguard
    set proxy-server-ip 172.16.200.44
    set proxy-server-port 3128
    set proxy-username "test1"
    set proxy-password *****
end
```

To verify the explicit proxy connection to FortiGate Cloud Sandbox:

```
# diagnose debug application forticldd -1
Debug messages will be on for 30 minutes.
# diagnose debug enable
[2942] fds_handle_request: Received cmd 23 from pid=2526, len 0

```

Proxy chaining

For the explicit web proxy you can configure web proxy forwarding servers to use proxy chaining to redirect web proxy sessions to other proxy servers. Proxy chaining can be used to forward web proxy sessions from the FortiGate unit to one or more other proxy servers on your network or on a remote network. You can use proxy chaining to integrate the FortiGate explicit web proxy with a web proxy solution that you already have in place.

A FortiGate unit can forward sessions to most web proxy servers including a remote FortiGate unit with the explicit web proxy enabled. No special configuration of the explicit web proxy on the remote FortiGate unit is required.

You can deploy the explicit web proxy with proxy chaining in an enterprise environment consisting of small satellite offices and a main office. If each office has a FortiGate unit, users at each of the satellite offices can use their local FortiGate unit as an explicit web proxy server. The satellite office FortiGate units can forward explicit web proxy sessions to an explicit web proxy server at the central office. From here the sessions can connect to web servers on the Internet.

FortiGate proxy chaining does not support web proxies in the proxy chain authenticating each other.

The following examples assume explicit web proxy has been enabled.

To enable explicit web proxy in the GUI:

1. Go to *System > Feature Visibility*.
2. In the *Security Features* column, enable *Explicit Proxy*.
3. Configure the explicit web proxy settings. See [Explicit web proxy on page 292](#).

To add a web proxy forwarding server in the GUI:

1. Go to *Network > Explicit Proxy*. The *Explicit Proxy* page opens.
2. In the *Web Proxy Forwarding Servers* section, click *Create New*.
3. Configure the server settings:

Name	Enter the name of the forwarding server.
Proxy Address Type	Select the type of IP address of the forwarding server. A forwarding server can have an <i>FQDN</i> or <i>IP</i> address.
Proxy Address	Enter the IP address of the forwarding server.
Port	Enter the port number on which the proxy receives connections. Traffic leaving the FortiGate explicit web proxy for this server has its destination port number changed to this number.
Server Down Action	Select the action the explicit web proxy will take if the forwarding server is down. <ul style="list-style-type: none"> • <i>Block</i>: Blocks the traffic if the remote server is down. • <i>Use Original Server</i>: Forwards the traffic from the FortiGate to its destination as if no forwarding server is configured.
Health Monitor	Select to enable health check monitoring.
Health Check Monitor Site	Enter the address of a remote site.

4. Click *OK*.

Example

The following example adds a web proxy forwarding server named `fwd-srv` at address `proxy.example.com` and port 8080.

To add a web proxy forwarding server in the CLI:

```
config web-proxy forward-server
  edit fwd-srv
    set addr-type fqdn
    set fqdn proxy.example.com
    set port 8080
  next
end
```

Web proxy forwarding server monitoring and health checking

By default, a FortiGate unit monitors a web proxy forwarding server by forwarding a connection to the remote server every 10 seconds. The remote server is assumed to be down if it does not respond to the connection. FortiGate continues checking the server. The server is assumed to be back up when the server sends a response. If you enable health checking, the FortiGate unit attempts to get a response from a web server every 10 seconds by connecting through the remote forwarding server.

You can configure health checking for each remote server and specify a different website to check for each one.

If the remote server is found to be down you can configure the FortiGate unit to block sessions until the server comes back up or to allow sessions to connect to their destination, bypassing the remote forwarding server. You cannot configure the FortiGate unit to fail over to another remote forwarding server.

To configure proxy server monitor and health checking in the GUI:

1. Go to *Network > Explicit Proxy*. The *Explicit Proxy* page opens.
2. In the *Web Proxy Forwarding Servers* section, edit a server.
3. Configure the *Server Down Action* and *Health Monitor* settings.

Server Down Action	Select the action the explicit web proxy will take if the forwarding server is down. <ul style="list-style-type: none"> • <i>Block</i>: Blocks the traffic if the remote server is down. • <i>Use Original Server</i>: Forwards the traffic from the FortiGate to its destination as if no forwarding server configured.
Health Monitor	Select to enable health check monitoring.
Health Check Monitor Site	Enter the address of a remote site.

4. Click *OK*.

Example

The following example enables health checking for a web proxy forwarding server and sets the server down option to bypass the forwarding server if it is down.

To configure proxy server monitor and health checking in the CLI:

```
config web-proxy forward-server
  edit fwd-srv
    set healthcheck enable
    set monitor http://example.com
    set server-down-option pass
  next
end
```

Grouping forwarding servers and load balancing traffic to the servers

You can add multiple web proxy forwarding servers to a forwarding server group and then add the server group to an explicit web proxy policy instead of adding a single server. Forwarding server groups are created from the FortiGate CLI but can be added to policies from the web-based manager (or from the CLI).

When you create a forwarding server group you can select a load balancing method to control how sessions are load balanced to the forwarding servers in the server group. Two load balancing methods are available:

- *Weighted* load balancing sends more sessions to the servers with higher weights. You can configure the weight for each server when you add it to the group.
- *Least-session* load balancing sends new sessions to the forwarding server that is processing the fewest sessions.

When you create a forwarding server group you can also enable *affinity*. Enable affinity to have requests from the same client processed by the same server. This can reduce delays caused by using multiple servers for a single multi-step client operation. Affinity takes precedence over load balancing.

You can also configure the behavior of the group if all of the servers in the group are down. You can select to block traffic or you can select to have the traffic pass through the FortiGate explicit proxy directly to its destination instead of being sent to one of the forwarding servers.

Example

The following example adds a forwarding server group that uses weighted load balancing to load balance traffic to three forwarding servers. Server weights are configured to send most traffic to `server2`. The group has `affinity` enabled and blocks traffic if all of the forward servers are down.

To configure load balancing in the CLI:

```
config web-proxy forward-server
  edit server_1
    set ip 172.20.120.12
    set port 8080
  next
  edit server_2
    set ip 172.20.120.13
    set port 8000
  next
  edit server_3
    set ip 172.20.120.14
    set port 8090
  next
end

config web-proxy forward-server-group
  edit New-fwd-group
    set affinity enable
    set ldb-method weighted
    set group-down-option block
    config server-list
      edit server_1
        set weight 10
      next
      edit server_2
        set weight 40
      next
      edit server_3
        set weight 10
      next
    end
  next
end
```

Adding proxy chaining to an explicit web proxy policy

You can enable proxy chaining for web proxy sessions by adding a web proxy forwarding server or server group to an explicit web proxy policy. In a policy you can select one web proxy forwarding server or server group. All explicit web proxy traffic accepted by this security policy is forwarded to the specified web proxy forwarding server or server group.

To add an explicit web proxy forwarding server in the GUI:

1. Go to *Policy & Objects > Proxy Policy* and click *Create New*.
2. Configure the policy settings:

Proxy Type	Explicit Web
Outgoing Interface	wan1
Source	Internal_subnet
Destination	all
Schedule	always
Service	webproxy
Action	Accept

3. Enable *Web Proxy Forwarding Server* and select the forwarding server, (for example, *fwd-srv*).
4. Click *OK*.

Example

The following example adds a security policy that allows all users on the 10.31.101.0 subnet to use the explicit web proxy for connections through the wan1 interface to the Internet. The policy forwards web proxy sessions to a remote forwarding server named *fwd-srv*.

To add an explicit web proxy forwarding server in the CLI:

```
config firewall proxy-policy
  edit 0
    set proxy explicit-web
    set dstintf "wan1"
    set srcaddr "Internal_subnet"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set webproxy-forward-server "fwd-srv"
  next
end
```

Using TLS 1.3 with web proxy forward servers

A FortiGate can handle TLS 1.3 traffic in both deep and certificate inspection modes.

Example

The following example demonstrates that the Squid server and the FortiGate can handle TLS 1.3 traffic.

The following output from the Squid server demonstrates that the FortiGate supports TLS 1.3 traffic and forwards the hello retry request back to the client PC. The client PC then sends the client hello again, and the connection is successfully established.

No.	Time	Source	Destination	Protocol	Length	Info
1	0.000000	10.1.100.66	10.1.100.66	TCP	70	58896 → 443 [SYN] Seq=0 Win=64240 Len=0 MSS=1460 SACK_PERM=1 TSval=84354029 TSecr=0 WS=128

WAN optimization SSL proxy chaining

An SSL server does not need to be defined for WAN optimization (WANOpt) SSL traffic offloading (traffic acceleration). The server side FortiGate uses an SSL profile to resign the HTTP server's certificate, both with and without an external proxy, without an SSL server configured. GCM and ChaCha ciphers can also be used in the SSL connection.

Examples

In these examples, HTTPS traffic is accelerated without configuring an SSL server, including with a proxy in between, and when the GCM or ChaCha ciphers are used.

Example 1

In this example, the server certificate is resigned by the server side FortiGate, and HTTPS traffic is accelerated without configuring an SSL server.

HTTPS traffic with the GCM or ChaCha cipher can pass through WANOpt tunnel.

To configure FGT_A:

1. Configure the hard disk to perform WANOpt:

```
config system storage
    edit "HDD2"
        set status enable
        set usage wanopt
        set wanopt-mode mix
    next
end
```

2. Configure the WANOpt peer and profile:

```
config wanopt peer
    edit "FGT-D"
        set ip 120.120.120.172
    next
end

config wanopt profile
    edit "test"
        config http
            set status enable
            set ssl enable
        end
    next
end
```

3. Create an SSL profile with deep inspection on HTTPS port 443:

```
config firewall ssl-ssh-profile
    edit "ssl"
        config https
            set ports 443
            set status deep-inspection
        end
    next
end
```

4. Configure a firewall policy in proxy mode with WANOpt enabled and the WANOpt profile selected:

```
config firewall policy
    edit 1
        set name "WANOPT-A"
```

```

        set srcintf "port21"
        set dstintf "port27"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
        set wanopt enable
        set wanopt-profile "test"
        set nat enable
    next
end

```

To configure FGT_D:

1. Configure the hard disk to perform WANOpt:

```

config system storage
    edit "HDD2"
        set status enable
        set usage wanopt
        set wanopt-mode mix
    next
end

```

2. Configure the WANOpt peer:

```

config wanopt peer
    edit "FGT-A"
        set ip 110.110.110.171
    next
end

```

3. Create an SSL profile with deep inspection on HTTPS port 443. The default *Fortinet_CA_SSL* certificate is used to resign the server certificate:

```

config firewall ssl-ssh-profile
    edit "ssl"
        config https
            set ports 443
            set status deep-inspection
        end
    next
end

```

4. Configure a firewall policy in proxy mode with WANOpt enabled and passive WANOpt detection:

```

config firewall policy
    edit 1
        set name "WANOPT-B"
        set srcintf "port27"
        set dstintf "port23"
        set action accept
        set srcaddr "all"
    next
end

```

```

        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set wanopt enable
        set wanopt-detection passive
        set nat enable
    next
end

```

5. Configure a proxy policy to apply the SSL profile:

```

config firewall proxy-policy
    edit 100
        set proxy wanopt
        set dstintf "port23"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        set action accept
        set schedule "always"
        set utm-status enable
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
    next
end

```

To confirm that traffic is accelerated:

1. On the client PC, curl a 10MB test sample for the first time:

```

root@client:/tmp# curl -k https://172.16.200.144/test_10M.pdf -O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100 9865k  100 9865k    0     0   663k      0  0:00:14  0:00:15 --:--:-- 1526k

```

It takes 15 seconds to finish the download.

2. On FGT_A, check the WAD statistics:

```

# diagnose wad stats worker.tunnel
comp.n_in_raw_bytes      10155840
comp.n_in_comp_bytes     4548728
comp.n_out_raw_bytes      29624
comp.n_out_comp_bytes     31623

# diagnose wad stats worker.protos.http
wan.bytes_in              0
wan.bytes_out              0
lan.bytes_in              760
lan.bytes_out             10140606
tunnel.bytes_in           4548728
tunnel.bytes_out          31623

```

3. Curl the same test sample a second time:

```

root@client:/tmp# curl -k https://172.16.200.144/test_10M.pdf -O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed

```

						Dload	Upload	Total	Spent	Left	Speed
100	9865k	100	9865k	0	0	663k	0	0:00:01	0:00:01	--:--:--	1526k

It now takes less than one second to finish the download.

4. On FGT_A, check the WAD statistics again:

```
# diagnose wad stats worker.tunnel
comp.n_in_raw_bytes          10181157
comp.n_in_comp_bytes          4570331
comp.n_out_raw_bytes          31627
comp.n_out_comp_bytes         34702

# diagnose wad stats worker.protos.http
wan.bytes_in                   0
wan.bytes_out                  0
lan.bytes_in                   1607
lan.bytes_out                20286841
tunnel.bytes_in                4570331
tunnel.bytes_out               34702
```

The tunnel bytes are mostly unchanged, but the LAN bytes are doubled. This means that the bytes of the second curl come from the cache, showing that the traffic is accelerated.

To confirm that a curl using the GCM cipher is accepted and accelerated:

1. On the client PC, curl a 10MB test sample with the GCM cipher:

```
root@client:/tmp# curl -v -k --ciphers DHE-RSA-AES128-GCM-SHA256
https://172.16.200.144/test_10M.pdf -O
* Trying 172.16.200.144...
* TCP_NODELAY set
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left   Speed
  0     0     0     0     0     0      0      0 --:--:-- --:--:-- --:--:--    0*

To confirm that a curl using the ChaCha cipher is accepted and accelerated:

1. On the client PC, curl a 10MB test sample with the ChaCha cipher:

```

root@client:/tmp# curl -v -k --ciphers ECDHE-RSA-CHACHA20-POLY1305
https://172.16.200.144/test.doc -O
* Trying 172.16.200.144...
* TCP_NODELAY set
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left   Speed
  0     0    0     0    0     0      0      0 --:--:-- --:--:-- --:--:--    0*
Connected to 172.16.200.144 (172.16.200.144) port 443 (#0)

```

Example 2

In this example, an external proxy is added to the configuration in [Example 1](#).

To reconfigure FGT_A:

```

config firewall profile-protocol-options
  edit "protocol"
    config http
      set ports 80 8080
      unset options
      unset post-lang
    end
  next
end

```

To reconfigure FGT_D:

1. Configure a new firewall policy for traffic passing from port27 to port29:

```

config firewall policy
  edit 1
    set name "WANOPT-B"
    set srcintf "port27"
    set dstintf "port29"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set inspection-mode proxy
    set wanopt enable
    set wanopt-detection passive
    set nat enable
  next
end

```

2. Configure a proxy policy for traffic on destination interface port29:

```

config firewall proxy-policy
  edit 100
    set proxy wanopt
    set dstintf "port29"
    set srcaddr "all"
    set dstaddr "all"
    set service "ALL"
    set action accept
  end

```

```

        set schedule "always"
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
    next
end

```

To confirm that HTTPS traffic is still being accelerated:

1. On the client PC, curl the same 10MB test sample through the explicit proxy:

```

root@client:/tmp# curl -x 100.100.100.174:8080 -v -k https://172.16.200.144/test_10M.pdf
-O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left   Speed
100 9865k  100 9865k    0     0   663k      0  0:00:01  0:00:01 --:--:-- 1526k

```

It takes less than a second to finish the download.

Agentless NTLM authentication for web proxy

Agentless Windows NT LAN Manager (NTLM) authentication includes support for the following items:

- Multiple servers
- Individual users

You can use multiple domain controller servers for the agentless NTLM. They can be used for load balancing and high service stability.

You can also use user-based matching in groups for Kerberos and agentless NTLM. In these scenarios, FortiOS matches the user's group information from an LDAP server.

To support multiple domain controllers for agentless NTLM using the CLI:

1. Configure an LDAP server:

```

config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.177"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *****
    next
end

```

2. Configure multiple domain controllers:

```

config user domain-controller
    edit "dc1"
        set ip-address 172.18.62.177
        config extra-server
            edit 1
                set ip-address 172.18.62.220
            next
        end
    end

```

```

        set ldap-server "ldap-kerberos"
    next
end

```

3. Create an authentication scheme and rule:

```

config authentication scheme
    edit "au-ntlm"
        set method ntlm
        set domain-controller "dc1"
    next
end

config authentication rule
    edit "ru-ntlm"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "au-ntlm"
    next
end

```

4. In the proxy policy, append the user group for authorization:

```

config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set groups "ldap-group"
        set utm-status enable
        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
    next
end

```

This configuration uses a round-robin method. When the first user logs in, the FortiGate sends the authentication request to the first domain controller. Later when another user logs in, the FortiGate sends the authentication request to another domain controller.

5. Verify the behavior after the user successfully logs in:

```

# diagnose wad user list
ID: 1825, IP: 10.1.100.71, VDOM: vdom1
  user name      : test1
  duration       : 497
  auth_type      : Session
  auth_method    : NTLM
  pol_id         : 1    g_id           : 5
  user_based     : 0    e
  xpire          : 103
LAN:
  bytes_in=2167 bytes_out=7657
WAN:
  bytes_in=3718 bytes_out=270

```

To support individual users for agentless NTLM using the CLI:**1. Configure an LDAP server:**

```
config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.177"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *****
    next
end
```

2. Configure the user group and allow user-based matching:

```
config user group
    edit "ldap-group"
        set member "ldap" "ldap-kerberos"
        config match
            edit 1
                set server-name "ldap-kerberos"
                set group-name "test1"
            next
        end
    next
end
```

3. Create an authentication scheme and rule:

```
config authentication scheme
    edit "au-ntlm"
        set method ntlm
        set domain-controller "dc1"
    next
end

config authentication rule
    edit "ru-ntlm"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "au-ntlm"
    next
end
```

4. In the proxy policy, append the user group for authorization:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set groups "ldap-group"
        set utm-status enable
```

```

        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
    next
end

```

This implementation lets you configure a single user instead of a whole group. The FortiGate will now allow the user named `test1`.

To verify the configuration using the CLI:

```

diagnose wad user list
ID: 1827, IP: 10.1.15.25, VDOM: vdom1
user name   : test1
duration    : 161
auth_type   : Session
auth_method : NTLM
pol_id      : 1
g_id        : 5
user_based  : 0
expire      : 439
LAN:
    bytes_in=1309 bytes_out=4410
WAN:
    bytes_in=2145 bytes_out=544

```

Multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers

Multiple LDAP servers can be configured in Kerberos keytabs and agentless NTLM domain controllers for multi-forest deployments.

To use multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers:

1. Add multiple LDAP servers:

```

config user ldap
    edit "ldap-kerberos"
        set server "172.16.200.98"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password xxxxxxxxxx
    next
    edit "ldap-two"
        set server "172.16.106.128"
        set cnid "cn"
        set dn "OU=Testing,DC=ad864r2,DC=com"
        set type regular
        set username "cn=Testadmin,cn=users,dc=AD864R2,dc=com"
        set password xxxxxxxxxx
    next
end

```

2. Configure a Kerberos keytab entry that uses both LDAP servers:

```

config user krb-keytab
    edit "http_service"
        set pac-data disable
        set principal "HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL"
        set ldap-server "ldap-kerberos" "ldap-two"
        set keytab xxxxxxxxxx
    next
end

```

3. Configure a domain controller that uses both LDAP servers:

```

config user domain-controller
    edit "dc1"
        set ip-address 172.16.200.98
        set ldap-server "ldap-two" "ldap-kerberos"
    next
end

```

Learn client IP addresses

Learning the actual client IP addresses is imperative for authorization. This function identifies the real client IP address when there is a NATing device between the FortiGate and the client.

```

config web-proxy global
    set learn-client-ip {enable | disable}
    set learn-client-ip-from-header {true-client-ip | x-real-ip | x-forwarded-for}
    set learn-client-ip-srcaddr <address> ... <address>
end

```

learn-client-ip {enable disable}	Enable/disable learning the client's IP address from headers.
learn-client-ip-from-header {true-client-ip x-real-ip x-forwarded-for}	Learn client IP addresses from the specified headers.
learn-client-ip-srcaddr <address> ... <address>	The source address names.

Example

In this example, the real client IP address is used to match a policy for FSSO authentication.

To enable learning the client IP address:

```

config web-proxy global
    set proxy-fqdn "default.fqdn"
    set webproxy-profile "default"
    set learn-client-ip enable
        set learn-client-ip-from-header x-forwarded-for
    set learn-client-ip-srcaddr "all"
end

```

To configure the proxy policy:

```
config firewall proxy-policy
  edit 1
    set proxy explicit-web
    set dstintf "mgmt1"
    set srcaddr "all"
    set dstaddr "all"
    set service "w"
    set action accept
    set schedule "always"
    set groups "fssol"
    set utm-status enable
    set av-profile "default"
    set dlp-profile "default"
    set profile-protocol-options "default"
    set ssl-ssh-profile "deep-inspection"
  next
end
```

To configure the authentication scheme and rule:

```
config authentication scheme
  edit "scheme1"
    set method fsso
  next
end

config authentication rule
  edit "rule1"
    set srcaddr "all"
    set sso-auth-method "scheme1"
  next
end
```

Explicit proxy authentication over HTTPS

When a HTTP request requires authentication in an explicit proxy, the authentication can be redirected to a secure HTTPS captive portal. Once authentication is complete, the client can be redirected back to the original destination over HTTP.

Example

A user visits a website via HTTP through the explicit web proxy on a FortiGate. The user is required to authenticate by either basic or form IP-based authentication for the explicit web proxy service. The user credentials need to be transmitted over the networks in a secured method over HTTPS rather than in plain text. The user credentials are protected by redirecting the client to a captive portal of the FortiGate over HTTPS for authentication where the user credentials are encrypted and transmitted over HTTPS.

In this example, explicit proxy authentication over HTTPS is configured with form IP-based authentication. Once configured, you can enable authorization for an explicit web proxy by configuring users or groups in the firewall proxy policy.

To configure explicit proxy authentication over HTTPS:

1. Configure the authentication settings:

```
config authentication setting
    set captive-portal-type fqdn
    set captive-portal "fgt-cp"
    set auth-https enable
end
```

2. Configure the authentication scheme:

```
config authentication scheme
    edit "form"
        set method form
        set user-database "local-user-db"
    next
end
```

3. Configure the authentication rule:

```
config authentication rule
    edit "form"
        set srcaddr "all"
        set active-auth-method "form"
    next
end
```

If a session-based basic authentication method is used, enable `web-auth-cookie`.

4. Configure the firewall address:

```
config firewall address
    edit "fgt-cp"
        set type fqdn
        set fqdn "fgt.fortinetqa.local"
    next
end
```

5. Configure the interface:

```

config system interface
  edit "port10"
    set ip 10.1.100.1 255.255.255.0
    set explicit-web-proxy enable
    set proxy-captive-portal enable
  next
end

```

6. Configure a firewall proxy policy with users or groups (see [Explicit web proxy on page 292](#)).

Verification

When a client visits a HTTP website, the client will be redirected to the captive portal for authentication by HTTPS. For example, the client could be redirected to a URL by a HTTP 303 message similar to the following:

HTTP/1.1 303 See Other

Connection: close

Content-Type: text/html

Cache-Control: no-cache

Location:

https://fgt.fortinetqa.local:7831/XX/YY/ZZ/cpauth?scheme=http&Tmthd=0&host=172.16.200.46&port=80&rule=75&uri=Lw==&

Content-Length: 0

The captive portal URL used for authentication is *https://fgt.fortinetqa.local:7831/....* Once the authentication is complete with all user credentials protected by HTTPS, the client is redirected to the original HTTP website they intended to visit.

mTLS client certificate authentication

FortiGate supports client certificate authentication used in mutual Transport Layer Security (mTLS) communication between a client and server. Clients are issued certificates by the CA, and an access proxy configured on the FortiGate uses the new certificate method in the authentication scheme to identify and approve the certificate provided by the client when they try to connect to the access proxy. The FortiGate can also add the HTTP header X-Forwarded-Client-Cert to forward the certificate information to the server.

Examples

In these examples, the access proxy VIP IP address is 10.1.100.200.

Example 1

In this example, clients are issued unique client certificates from your CA. The FortiGate authenticates the clients by their user certificate before allowing them to connect to the access proxy. The access server acts as a reverse proxy for the web server that is behind the FortiGate.

This example assumes that you have already obtained the public CA certificate from your CA, the root CA of the client certificate has been imported (CA_Cert_1), and the client certificate has been distributed to the endpoints.

To configure the FortiGate:

1. Configure user authentication. Both an authentication scheme and rule must be configured, as the authentication is applied on the access proxy:

```
config authentication scheme
    edit "mtls"
        set method cert
        set user-cert enable
    next
end

config authentication rule
    edit "mtls"
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set active-auth-method "mtls"
    next
end
```

2. Select the CA or CAs used to verify the client certificate:

```
config authentication setting
    set user-cert-ca "CA_Cert_1"
end
```

3. Configure the users. Users can be matched based on either the common-name on the certificate or the trusted issuer.

- Verify the user based on the common name on the certificate:

```
config user certificate
    edit "single-certificate"
        set type single-certificate
        set common-name "client.fortinet.com"
    next
end
```

- Verify the user based on the CA issuer:

```
config user certificate
    edit "trusted-issuer"
        set type trusted-issuer
        set issuer "CA_Cert_1"
    next
end
```

4. Configure the access proxy VIP. The SSL certificate is the server certificate that is presented to the user as they connect:

```

config firewall vip
  edit "mTLS"
    set type access-proxy
    set extip 10.1.100.200
    set extintf "port2"
    set server-type https
    set extport 443
    set ssl-certificate "Fortinet_CA_SSL"
  next
end

```

5. Configure the access proxy policy, including the real server to be mapped. To request the client certificate for authentication, `client-cert` is enabled:

```

config firewall access-proxy
  edit "mTLS-access-proxy"
    set vip "mTLS"
    set client-cert enable
    set empty-cert-action accept
    config api-gateway
      edit 1
        config realservers
          edit 1
            set ip 172.16.200.44
          next
        end
      next
    end
  next
end

```

6. Configure the proxy policy to apply authentication and the security profile, selecting the appropriate user object depending on the user type:

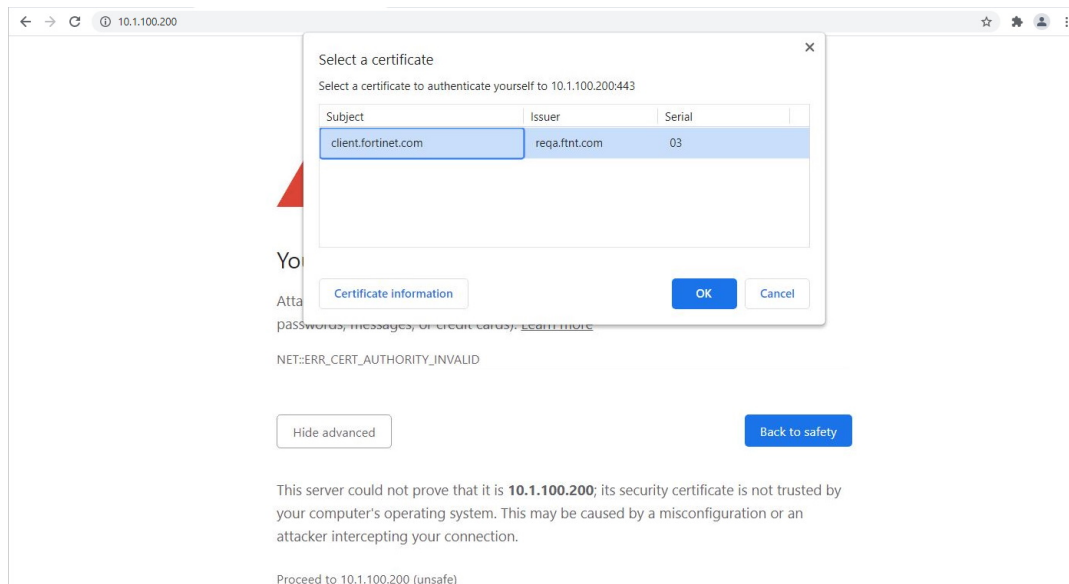

```

config firewall proxy-policy
  edit 3
    set proxy access-proxy
    set access-proxy "mTLS-access-proxy"
    set srcintf "port2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set users {"single-certificate" | "trusted-issuer"}
    set utm-status enable
    set ssl-ssh-profile "deep-inspection-clone"
    set av-profile "av"
  next
end

```

To verify the results:

1. In a web browser, access the VIP address. This example uses Chrome.
2. When prompted, select the client certificate, then click *OK*.

3. Click *Certificate information* to view details about the certificate.

4. On the FortiGate, check the traffic logs.

- If client certificate authentication passes:

```
1: date=2021-06-03 time=15:48:36 eventtime=1622760516866635697 tz="-0700"
logid="0000000010" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=45532 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=172.16.200.44 dstport=443
dstintf="vdom1" dstintfrole="undefined" sessionid=154900 service="HTTPS"
wanoptapptype="web-proxy" proto=6 action="accept" policyid=3 policytype="proxy-
policy" poluuid="af5e2df2-c321-51eb-7d5d-42fa58868dcb" duration=0 user="single-
certificate" wanin=2550 rcvdbyte=2550 wanout=627 lanin=4113 sentbyte=4113 lanout=2310
appcat="unscanned"
```

- If the CA issuer is used to verify the client:

```
1: date=2021-06-03 time=15:43:02 eventtime=1622760182384776037 tz="-0700"
logid="0000000010" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=45514 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=10.1.100.200 dstport=443
dstintf="vdom1" dstintfrole="undefined" sessionid=153884 service="HTTPS"
```

```
wanoptapptype="web-proxy" proto=6 action="accept" policyid=3 policytype="proxy-policy" poluuid="af5e2df2-c321-51eb-7d5d-42fa58868dcb" duration=0 user="trusted-issuer" wanin=0 rcvdbyte=0 wanout=0 lanin=4089 sentbyte=4089 lanout=7517 appcat="unscanned" utmaction="block" countweb=1 crscore=30 craction=8 utmref=65535-0
```

- If the client certificate authentication fails, and the traffic is blocked:

```
1: date=2021-06-03 time=15:45:53 eventtime=1622760353789703671 tz="-0700"
logid="0000000013" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=45518 srcintf="port2" srcintfrole="undefined"
dstip=172.16.200.44 dstport=443 dstintf="vdom1" dstintfrole="undefined"
srccountry="Reserved" dstcountry="Reserved" sessionid=154431 proto=6 action="deny"
policyid=0 policytype="proxy-policy" user="single-certificate" service="HTTPS"
trandisp="noop" url="https://10.1.100.200/" agent="curl/7.68.0" duration=0 sentbyte=0
rcvdbyte=0 sentpkt=0 rcvdpkt=0 appcat="unscanned" crscore=30 craction=131072
crlevel="high" msg="Traffic denied because of explicit proxy policy"
```

Example 2

In this example, the same configuration as in [Example 1](#) is used, with a web proxy profile added to enable adding the client certificate to the HTTP header X-Forwarded-Client-Cert. The header is then forwarded to the server.

To configure the FortiGate:

1. Repeat steps 1 to 6 of [Example 1](#), using the common name on the certificate to verify the user.
2. Configure a web proxy profile that adds the HTTP x-forwarded-client-cert header in forwarded requests:

```
config web-proxy profile
  edit "mtls"
    set header-x-forwarded-client-cert add
  next
end
```

3. Configure the proxy policy to apply authentication, the security profile, and web proxy profile:

```
config firewall proxy-policy
  edit 3
    set uuid af5e2df2-c321-51eb-7d5d-42fa58868dcb
    set proxy access-proxy
    set access-proxy "mTLS-access-proxy"
    set srcintf "port2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set logtraffic all
    set users "single-certificate"
    set webproxy-profile "mtls"
    set utm-status enable
    set ssl-ssh-profile "deep-inspection-clone"
    set av-profile "av"
  next
end
```

To verify the results:

The WAD debug shows that the FortiGate adds the client certificate information to the HTTP header. The added header cannot be checked using the sniffer, because the FortiGate encrypts the HTTP header to forward it to the server.

1. Enable WAD debug on all categories:

```
# diagnose wad debug enable category all
```

2. Set the WAD debug level to verbose:

```
# diagnose wad debug enable level verbose
```

3. Enable debug output:

```
# diagnose debug enable
```

4. Check the debug output.

- When the FortiGate receives the client HTTP request:

```
[0x7fc8d4bc4910] Received request from client: 10.1.100.11:45544

GET / HTTP/1.1
Host: 10.1.100.200
User-Agent: curl/7.68.0
Accept: */*
```

- When the FortiGate adds the client certificate in to the HTTP header and forwards the client HTTP request:

```
[0x7fc8d4bc4910] Forward request to server:
GET / HTTP/1.1
Host: 172.16.200.44
User-Agent: curl/7.68.0
Accept: */*
X-Forwarded-Client-Cert: -----BEGIN CERTIFICATE-----
MIIFXzCCA0egAwI...aCFHDHlR+wb39s=
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIFpTCCA42gAwI...OtDtetkNoFLbvb
-----END CERTIFICATE-----
```

CORS protocol in explicit web proxy when using session-based, cookie-enabled, and captive portal-enabled SAML authentication

The FortiGate explicit web proxy supports the Cross-Origin Resource Sharing (CORS) protocol, which allows the FortiGate to process a CORS preflight request and an actual CORS request properly, in addition to a simple CORS request when using session-based, cookie-enabled, and captive portal-enabled SAML authentication. This allows a FortiGate explicit web proxy user with this specific configuration to properly view a web page requiring CORS with domains embedded in it other than its own domain.

To configure the FortiGate:

1. Configure the authentication rule:

```
config authentication rule
  edit "saml"
    set srcaddr "all"
    set ip-based disable
    set active-auth-method "saml"
    set web-auth-cookie enable
  next
end
```

2. Configure the captive portal:

```
config authentication setting
  set captive-portal "fgt9.myqalab.local"
end
```

3. Configure the proxy policy

```
config firewall proxy-policy
  edit 3
    set proxy explicit-web
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set logtraffic all
    set groups "ldap-group-saml"
    set utm-status enable
    set profile-protocol-options "protocol"
    set ssl-ssh-profile "deep-custom"
    set av-profile "av"
    set application-list "fff"
```

```

    next
end

```

CORS request scenarios

Preflight CORS request

The client sends the initial CORS preflight request (OPTIONS with the origin header) to the web server through FortiGate's web proxy and receives a CORS 200 OK response (with headers, such as Access-Control-Allow-Origin). The FortiGate will not redirect the client to the captive capital for authentication:

```

> OPTIONS /bidRequest HTTP/1.1
> Host: c2shb.pubgw.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Access-Control-Request-Method: GET
> Access-Control-Request-Headers: content-type,x-openrtb-version
> Origin: https://www.cnn.com
...
< HTTP/1.1 200 OK
< Date: Thu, 19 May 2022 01:49:17 GMT
< Content-Length: 0
< Server: ATS/9.1.0.46
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Methods: GET,POST,OPTIONS
< Access-Control-Allow-Headers: X-Requested-With,Content-Type,X-Openrtb-Version
< Access-Control-Allow-Credentials: true
< Access-Control-Max-Age: 600
< Age: 0
< Connection: keep-alive
< Set-Cookie: A3=d=AQABBB2ihWICEIUyD_Du5ol8tMdKKWxspR8FEgEBAQHzhmKPYgAAAAAA_
eMAAA&S=AQAAAlU0dAheQx6euvCps8ErK4I; Expires=Fri, 19 May 2023 07:49:17 GMT; Max-
Age=31557600; Domain=.yahoo.com; Path=/; SameSite=None; Secure; HttpOnly

```

Real CORS request

Once the initial preflight request for the client is successful, the client sends the real CORS request (GET request with origin header) to the FortiGate, The FortiGate then replies with a 30x response to redirect the client to the captive portal. The 30x response includes CORS headers such as Access-Control-Allow-Origin:

```

> GET /bidRequest HTTP/1.1
> Host: c2shb.pubgw.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Origin: https://www.cnn.com
...
< HTTP/1.1 303 See Other
< Access-Control-Max-Age: 1
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Credentials: true
< Set-Cookie: FTNT-EP-
FG900D3915800054=pqWlpdswdcCnpaWli6WlpcjEwszGmJbGksbBwMCVwcPBlpKRnMGTl52QxJeUwYPWl8aYlJWLlIu
UlZWLlJalPQ==; Path=/; Domain=.pubgw.yahoo.com; HttpOnly; SameSite=None; Secure
< Connection: close
< Content-Type: text/html

```

```
< Cache-Control: no-cache
< Location:
https://fgt9.myqalab.local:7831/test/saml/login/?cptype=ckauth&scheme=https&4Tmthd=0&host=c2
shb.pubgw.yahoo.com&port=443&rule=98&uri=L2JpZFJlcXVlc3Q=&cdata=pqWlpdswdcCnpaWli6WlpcjEwszG
mJbGksbBwMCVvcPBlpKRnMGTl52QxJeUwYPWl8aYlJWLLlIuUlZWLLlJalpq==
< Content-Length: 0
```

Redirection to captive portal

Once the client's real CORS request is redirected to the captive portal, the client sends another preflight to the captive portal. The captive portal then replies with a 20x response, which includes CORS headers such as `Access-Control-Allow-Origin`:

```
> OPTIONS
/test/saml/login/?cptype=ckauth&scheme=https&4Tmthd=1&host=gql.reddit.com&port=443&rule=98&u
ri=Lw==&cdata=pqWlpQM5dcCnpaWliqWlpcjEwszGmJbGksbAk5WTl8aTwJDGnJ2Tl52QxpHDkYPWl8aYlJWLLlIuUlZ
WLLJGWpQ== HTTP/1.1
> Host: fgt9.myqalab.local:7831
> Connection: keep-alive
> Accept: */*
> Access-Control-Request-Method: GET
> Access-Control-Request-Headers: authorization,content-type,x-reddit-compression,x-reddit-
loid,x-reddit-session
> Origin: null
> User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like
Gecko) Chrome/100.0.4896.75 Safari/537.36 Edg/100.0.1185.36
> Sec-Fetch-Mode: cors
> Sec-Fetch-Site: cross-site
> Sec-Fetch-Dest: empty
> Referer: https://www.reddit.com/
> Accept-Encoding: gzip, deflate, br
> Accept-Language: en-US,en;q=0.9
...
< HTTP/1.1 204 No Content
< Access-Control-Max-Age: 86400
< Access-Control-Allow-Methods: GET
< Access-Control-Allow-Headers: authorization,content-type,x-reddit-compression,x-reddit-
loid,x-reddit-session
< Access-Control-Allow-Origin: null
< Access-Control-Allow-Credentials: true
```

Simple CORS request

If a simple CORS request (no preflight request sent before it) is used, when the FortiGate receives the simple request, it replies with a 30x response that includes CORS headers, such as `Access-Control-Allow-Origin`:

```
> Host: www.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Origin: https://www.cnn.com
...
< HTTP/1.1 303 See Other
< Access-Control-Max-Age: 1
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Credentials: true
< Set-Cookie: FTNT-EP-
```

```

FG900D3915800000=pqWlpaw7dcCnpaWli6WlpcjEwszGmJbGksbAkpOcxMDDlpbGlmSTl52QwcGcl4PWl8aYlJWLlIu
UlZWlJlJalpQ==; Path=/; Domain=.yahoo.com; HttpOnly; SameSite=None; Secure
< Connection: close
< Content-Type: text/html
< Cache-Control: no-cache
< Location:

< Content-Length: 0

```

Display CORS content in an explicit proxy environment - NEW

Webpages can display Cross-Origin Resource Sharing (CORS) content in an explicit proxy environment when using session-based, cookie-enabled, and captive portal assisted authentication. This ensures that webpages are displayed correctly and improves the user experience.

```

config authentication rule
    edit <name>
        set web-auth-cookie enable
        set cors-stateful {enable | disable}
        set cors-depth <integer>
    next
end

```

<code>cors-stateful {enable disable}</code>	Enable/disable allowing CORS access (default = disable). This setting is only available when <code>web-auth-cookie</code> is enabled.
<code>cors-depth <integer></code>	Set the depth to allow CORS access (1 - 8, default = 3). For example, when visiting domain A, the returned web page may refer the browser to a cross-origin domain B (depth of 1). When the browser visits domain B, the returned web content may further refer the browser to another cross-origin domain C (depth of 2).

Example

CORS access is enabled in this example. When a user access the Microsoft *Sign in* page using an explicit proxy, the page appears and the user can log in. This example assumes the web proxy and user group have already been configured, and that the proxy captive portal setting has been enabled on the appropriate interface.

To view CORS content in an explicit proxy environment:

1. Configure the authentication scheme:

```

config authentication scheme
    edit "form"
        set method form
        set user-database "local-user-db"
    next
end

```

2. Configure the authentication rule:

```
config authentication rule
  edit "form"
    set srcaddr "all"
    set ip-based disable
    set active-auth-method "form"
    set web-auth-cookie enable
    set cors-stateful enable
    set cors-depth 3
  next
end
```

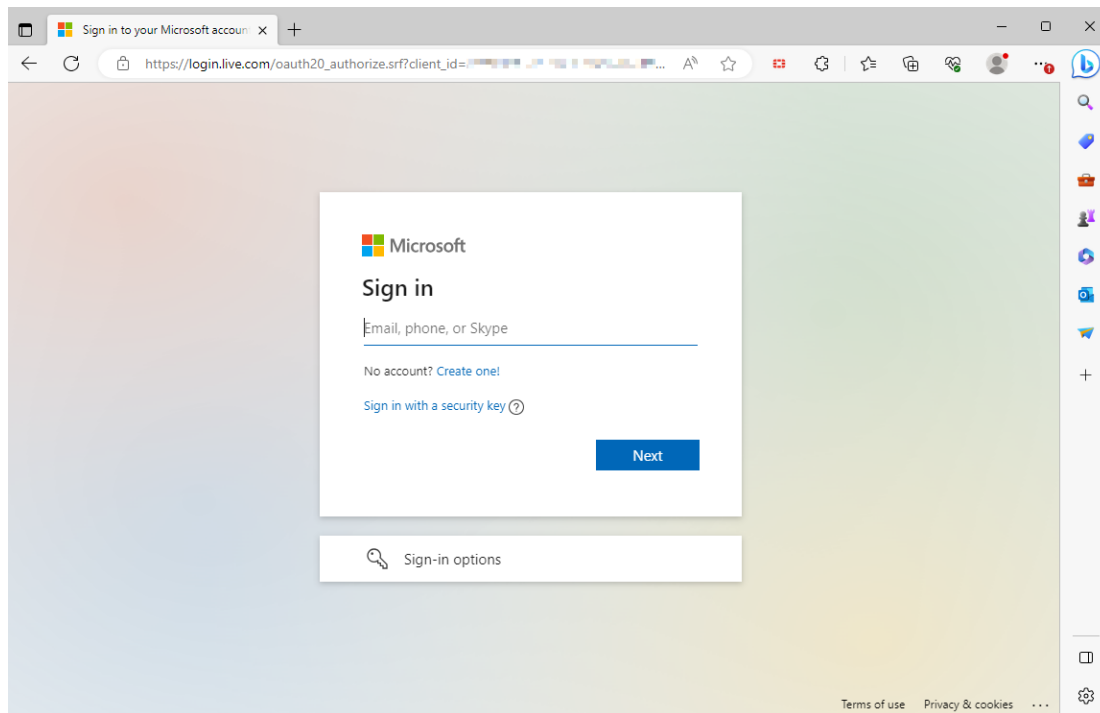

3. Configure the captive portal:

```
config authentication setting
  set captive-portal "fgt9.myqalab.local"
end
```

4. Configure the proxy policy:

```
config firewall proxy-policy
  edit 1
    set proxy explicit-web
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set logtraffic all
    set groups "localgroup"
    set utm-status enable
    set ssl-ssh-profile "deep-custom"
    set av-profile "av"
  next
end
```

- 5.** Get a user to access login.microsoftonline.com through the explicit web proxy. The *Sign in* page appears, and the user can log in.

If CORS access (`cors-stateful`) was disabled, the browser would load a blank page.

HTTP connection coalescing and concurrent multiplexing for explicit proxy

HTTP connection coalescing and concurrent multiplexing allows multiple HTTP requests to share the same TCP three-way handshake when the destination IP is the same.

To configure the explicit web proxy:

```
config web-proxy explicit
    set http-connection-mode {static | multiplex | serverpool}
end
```

```
http-connection-mode
    {static | multiplex
    | serverpool}
```

Set the HTTP connection mode:

- **static:** only one server connection exists during the proxy session (default).
- **multiplex:** hold established connections until the proxy session ends.
- **serverpool:** share established connections with other proxy sessions.

Example

In this example, multiple clients submit requests in HTTP. The requests hit the VIP address, and then FortiGate opens a session between itself (172.16.200.6) and the server (172.16.200.99). The coalescing occurs in this session as the multiple streams share the same session to connect to the same destination server.

To configure connection coalescing and concurrent multiplexing with an explicit proxy:

1. Configure the explicit web proxy:

```

config web-proxy explicit
    set status enable
    set http-incoming-port 8080
    set http-connection-mode serverpool
end

```

2. Enable explicit web proxy on port2:

```

config system interface
    edit "port2"
        set ip 10.1.100.6 255.255.255.0
        set explicit-web-proxy enable
    next
end

```

3. Configure the proxy policy:

```

config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set utm-status enable
        set profile-protocol-options "default-clone"
        set ssl-ssh-profile "deep-inspection-clone"
    next
end

```

4. Get the clients to access the server through the explicit web proxy (10.1.100.6:8080). The FortiGate shares the first connection TCP three-way handshake with later connections that connect to same destination address.

5. Verify the sniffer packet capture on the FortiGate server side. There is one TCP three-way handshake, but there are two HTTP connections.

No.	Time	Source	Destination	Protocol	Length	Info
1	0.000000	172.16.200.6	172.16.200.99	TCP	76	8874 → 80 [SYN] Seq=0 Win=65535 Len=0 MSS=1460 SACK_PERM=1 TSval=288652 TSecr=0 WS=4096
2	0.000099	172.16.200.99	172.16.200.6	TCP	76	80 → 8874 [SYN, ACK] Seq=0 Ack=1 Win=65160 Len=0 MSS=1460 SACK_PERM=1 TSval=3489676249 TSecr=288652 WS=128
3	0.000114	172.16.200.6	172.16.200.99	TCP	68	8874 → 80 [ACK] Seq=1 Ack=1 Win=176128 Len=0 TSval=288652 TSecr=3489676249
4	0.000137	172.16.200.6	172.16.200.99	HTTP	169	GET / HTTP/1.1
5	0.000208	172.16.200.99	172.16.200.6	TCP	68	80 → 8874 [ACK] Seq=1 Ack=102 Win=65152 Len=0 TSval=3489676249 TSecr=288652
6	0.000503	172.16.200.99	172.16.200.6	HTTP	423	HTTP/1.1 200 OK (text/html)
7	0.000507	172.16.200.6	172.16.200.99	TCP	68	8874 → 80 [ACK] Seq=102 Ack=356 Win=176128 Len=0 TSval=288652 TSecr=3489676249
8	2.148158	172.16.200.6	172.16.200.99	HTTP	169	GET / HTTP/1.1
9	2.148419	172.16.200.99	172.16.200.6	HTTP	399	HTTP/1.1 200 OK (text/html)
10	2.148430	172.16.200.6	172.16.200.99	TCP	68	8874 → 80 [ACK] Seq=203 Ack=687 Win=176128 Len=0 TSval=288867 TSecr=3489678397

6. Change the HTTP connection mode to static:

```
config web-proxy explicit
    set status enable
    set http-incoming-port 8080
    set http-connection-mode static
end
```

7. Verify the sniffer packet capture. This time, the FortiGate establishes a TCP connection for each client.

No.	Time	Source	Destination	Protocol	Length	Info
1	0.000000	172.16.200.6	172.16.200.99	TCP	76	9082 → 80 [SYN] Seq=0 Win=65535 Len=0 MSS=1460 SACK_PERM=1 TSval=312906 TSecr=0 WS=4096

19	2.169965	172.16.200.99	172.16.200.6	TCP	68	80 → 9085 [FIN, ACK] Seq=356 Ack=103 Win=65152 Len=0 TSval=3489920957 TSecr=313123

Secure explicit proxy

Secure explicit web proxy with HTTPS connections is supported between web clients and the FortiGate.

```
config web-proxy explicit
    set secure-web-proxy {disable | enable | secure}
    set secure-web-proxy-cert <certificate1> <certificate2> ...
    set ssl-dh-bits {768 | 1024 | 1536 | 2048}
end
```

```
secure-web-proxy {disable
    | enable | secure}
```

Enable/disable/require the secure web proxy for HTTP and HTTPS session.

- **disable:** disable secure web proxy (default)
- **enable:** enable secure web proxy access, allowing both HTTPS and HTTP connections to the explicit proxy
- **secure:** require secure web proxy access, allowing only HTTPS connections to the explicit proxy

```
secure-web-proxy-cert
    <certificate1>
    <certificate2> ...
```

Enter the names of the server certificates in the local certificate store of the FortiGate used to establish a TLS connection between the user's browser and the FortiGate.

Multiple server certificates can be configured, and different certificate types can be used. The SNI tries to match the right server certificate for the connection. If the SNI cannot not match with the certificates' CN or SAN, the first server certificate will be offered.

```
ssl-dh-bits {768 | 1024 |
    1536 | 2048}
```

Set the bit size of Diffie-Hellman (DH) prime used in the DHE-RSA negotiation.

- 768: use 768-bit Diffie-Hellman prime
- 1024: use 1024-bit Diffie-Hellman prime
- 1536: use 1536-bit Diffie-Hellman prime
- 2048: use 2048-bit Diffie-Hellman prime (default)

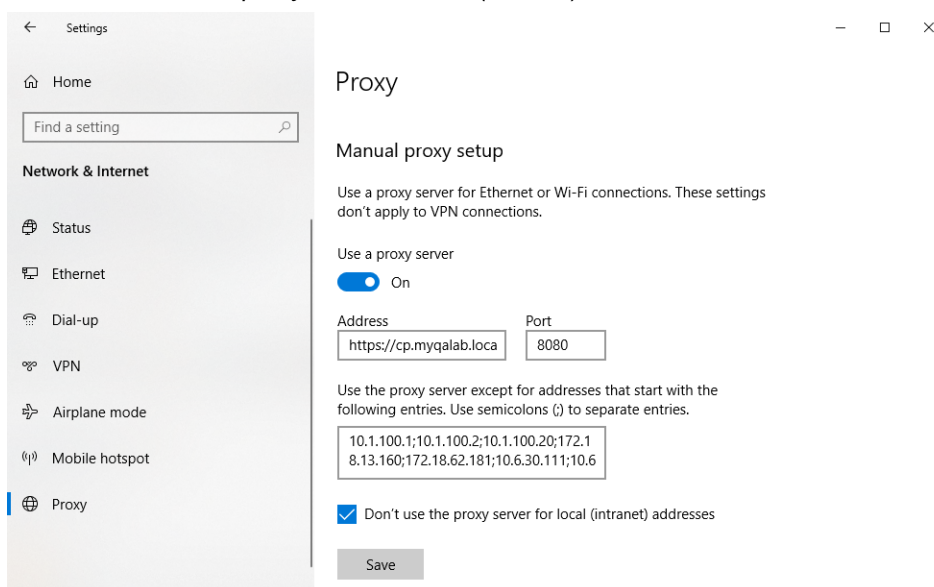

Example

In this example, a Windows PC user configures an HTTPS URL (<https://cp.myqalab.local>) as the proxy address for the explicit web proxy. When the user opens a browser (such as Edge or Chrome), the browser will use the HTTPS URL to connect to the explicit web proxy and send any HTTP requests to the proxy over HTTPS. The certificate (server_cert) contains the explicit web proxy's name (cp.myqalab.local) as its CN, so the browser will accept this certificate for the TLS connection.

To configure the Windows proxy settings:

1. On the Windows PC, go to *Settings > Network & Internet > Proxy*.
2. In the *Manual proxy setup* section configure the following:
 - a. Enable *Use a proxy server*.
 - b. Set the *Address* to <https://cp.myqalab.local>.
 - c. Set the *Port* to 8080.
 - d. If needed, enter any addresses to exempt in the text box (use a semicolon to separate entries).
 - e. Enable *Don't use the proxy server for local (intranet) addresses*.

3. Click **Save**.

To configure the secure explicit web proxy:

```
config web-proxy explicit
    set status enable
    set secure-web-proxy enable
    set ftp-over-http enable
    set socks enable
    set http-incoming-port 8080
    set secure-web-proxy-cert "server_cert"
    set socks-incoming-port 1080
    set ipv6-status enable
    set unknown-http-version best-effort
    set pac-file-server-status enable
    set pac-file-data "function FindProxyForURL(url, host) {
// testtest
return \"PROXY 10.1.100.1:8080\";
}
"
    set pac-file-through-https enable
end
```

To verify the TLS connection:

1. Perform a packet capture of HTTPS traffic between the web client and the web server. Wireshark is used in this example.
2. Locate the exchange between the web client (10.1.100.13) and the explicit web proxy (10.1.100.1:8080):

No.	Time	Source	Destination	Protocol	Length	Info
1	0.000000	10.1.100.13	10.1.100.1	TCP	74	59762 → 8080 [SYN] Seq=0 Win=64240 Len=0 MSS=1460 SACK_PERM=1 TSval=1943273046 TSecr=0 WS=128

After the client initiates the TLS connection to the explicit web proxy with a client hello packet, the web proxy is able to respond appropriately with a server hello packet to establish a TLS connection first before any HTTP messages are exchanged, and all HTTP messages will be protected by the TLS connection.

Explicit proxy logging

Explicit proxy traffic logging can be used to troubleshoot the HTTP proxy status for each HTTP transaction with the following:

- Monitor HTTP header requests and responses in the UTM web filter log. This requires an SSL deep inspection profile to be configured in the corresponding firewall policy.
- Log the explicit web proxy forward server name using `set log-forward-server`, which is disabled by default.

```
config web-proxy global
    set log-forward-server {enable | disable}
end
```

- Log TCP connection failures in the traffic log when a client initiates a TCP connection to a remote host through the FortiGate and the remote host is unreachable.

Basic configuration

The following FortiGate configuration is used in the three explicit proxy traffic logging use cases in this topic.

To configure the FortiGate:

1. Configure the web proxy profile:

```
config web-proxy profile
  edit "header"
    config headers
      edit 1
        set name "test_request_header"
        set action monitor-request
      next
      edit 2
        set name "ETag"
        set action monitor-response
      next
    end
  next
end
```

2. Enable forward server name logging in traffic:

```
config web-proxy global
  set proxy-fqdn "100D.qa"
  set log-forward-server enable
end
```

3. Configure the web filter banned word table to block any HTTP response containing the text, works:

```
config webfilter content
  edit 1
    set name "default"
    config entries
      edit "works"
        set status enable
        set action block
      next
    end
  next
end
```

4. Configure the web filter profile:

```
config webfilter profile
  edit "header"
    set feature-set proxy
    config web
      set bword-table 1
    end
    config ftgd-wf
      unset options
    end
    set log-all-url enable
    set extended-log enable
  end
```

```

        set web-extended-all-action-log enable
    next
end

```

5. Configure the web proxy forwarding server:

```

config web-proxy forward-server
    edit "fgt-b"
        set ip 172.16.200.20
    next
end

```

6. Configure the firewall policy:

```

config firewall policy
    edit 1
        set srcintf "port10"
        set dstintf "port9"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set webproxy-profile "header"
        set webproxy-forward-server "fgt-b"
        set ssl-ssh-profile "deep-inspection"
        set webfilter-profile "header"
        set logtraffic all
        set nat enable
    next
end

```

A firewall policy is used in this basic configuration example and the specific examples that follow. This feature also works for the explicit web proxy or transparent web proxy with proxy policies, and the configurations are similar:

- Example 1: apply the `web-proxy` profile and `webfilter` profile to the proxy policy.
- Example 2: apply the `webproxy-forward-server`.

Example 1: monitoring HTTP header requests

In this example, the user wants to monitor some HTTP headers in HTTP messages forwarded through a FortiGate proxy (either transparent or explicit proxy with a firewall policy in proxy mode or a proxy policy). When the monitored headers are detected, they will be logged in the UTM web filter log.

In the web proxy profile configuration, the following HTTP headers are monitored:

- `test_request_header`: this is a user-customized HTTP header.
- `ETag`: this is a HTTP header returned by the web server's 200 OK response.

Based on the web filter profile configuration, the monitored headers in the web proxy profile will only be logged when the HTTP response received by the FortiGate triggers a block action by the banned word table. The `log-all-url`, `extended-log`, and `web-extended-all-action-log` settings in the web filter profile must be enabled.

The following settings are required in the firewall policy:

- `set inspection-mode proxy`
- `set webproxy-profile "header"`
- `set ssl-ssh-profile "deep-inspection"`
- `set webfilter-profile "header"`
- `set logtraffic all`

To verify the configuration:

1. Send a HTTP request from the client:

```
curl -kv https://172.16.200.33 -H "test_request_header: aaaaa"
```

This command sends a HTTP request with the header `test_request_header: aaaaa` through the FortiGate. Since the response from the web server contains the word `works`, the response will be blocked by the web filter profile (`header`). During this process, two logs will be generated.

2. On the FortiGate, check the traffic logs:

```
# execute log filter category 3
1: date=2023-04-19 time=19:01:19 eventtime=1681956079146481995 tz="-0700"
logid="0314012288" type="utm" subtype="webfilter" eventtype="content" level="warning"
vd="vdom1" policyid=1 poluuid="4d8dc396-46e3-51ea-7f3f-ee328a5bd07b" policytype="policy"
sessionid=40980 srcip=10.1.100.13 srcport=54512 srccountry="Reserved" srcintf="port10"
srcintfrole="undefined" srcuuid="6ce0b8ca-30ae-51ea-a388-ceacbb4fb045"
dstip=172.16.200.33 dstport=443 dstcountry="Reserved" dstintf="port9"
dstintfrole="undefined" dstuuid="6ce0b8ca-30ae-51ea-a388-ceacbb4fb045" proto=6
httpmethod="GET" service="HTTPS" hostname="172.16.200.33" agent="curl/7.61.1"
profile="header" reqtype="direct" url="https://172.16.200.33/" sentbyte=0 rcvbyte=0
direction="incoming" action="blocked" banword="works" msg="URL was blocked because it
contained banned word(s)." rawdata="[REQ] test_request_header:=aaaaa|[RESP] Content-
Type=text/html|ETag=\"34-5b23b9d3b67f4\""
```

```
2: date=2023-04-19 time=19:01:19 eventtime=1681956079144896978 tz="-0700"
logid="0319013317" type="utm" subtype="webfilter" eventtype="urlmonitor" level="notice"
vd="vdom1" policyid=1 poluuid="4d8dc396-46e3-51ea-7f3f-ee328a5bd07b" policytype="policy"
sessionid=40980 srcip=10.1.100.13 srcport=54512 srccountry="Reserved" srcintf="port10"
srcintfrole="undefined" srcuuid="6ce0b8ca-30ae-51ea-a388-ceacbb4fb045"
dstip=172.16.200.33 dstport=443 dstcountry="Reserved" dstintf="port9"
dstintfrole="undefined" dstuuid="6ce0b8ca-30ae-51ea-a388-ceacbb4fb045" proto=6
httpmethod="GET" service="HTTPS" hostname="172.16.200.33" agent="curl/7.61.1"
profile="header" action="passthrough" reqtype="direct" url="https://172.16.200.33/"
sentbyte=724 rcvbyte=2769 direction="outgoing" msg="URL has been visited"
ratemethod="ip" cat=255 rawdata="[REQ] test_request_header:=aaaaa"
```

Log 1 is for the blocked HTTP response that contains both monitored headers, `test_request_header` and `ETag`, and their values, `aaaaa` and `34-5b23b9d3b67f4`, respectively. Log 2 is for the HTTP request passing through the FortiGate proxy that contains `test_request_header` and its `aaaaa` value in the `rawdata` field.

Example 2: logging the explicit web proxy forward server name

In this example, the user wants to see the name of the web proxy forward server in the traffic log when the traffic is forwarded by a web proxy forward server.

In the global web proxy settings, `log-forward-server` must be enabled.

The following settings are required in the firewall policy:

- `set inspection-mode proxy`
- `set webproxy-forward-server "fgt-b"`
- `set logtraffic all`

When a HTTP request is sent through the FortiGate proxy, the request will be forwarded by the FortiGate to the upstream proxy (fgt-b), and the forward server's name will be logged in the traffic log.

To verify the configuration:

1. Send a HTTP request from the client:

```
curl -kv https://www.google.com
```

2. On the FortiGate, check the traffic logs:

```
# execute log filter category 3
1: date=2023-04-19 time=19:51:33 eventtime=1681959093510003961 tz="-0700"
logid="0000000013" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.13 srcport=49762 srcintf="port10" srcintfrole="undefined"
dstip=142.250.217.100 dstport=443 dstintf="port9" dstintfrole="undefined"
srccountry="Reserved" dstcountry="United States" sessionid=43292 proto=6 action="client-
rst" policyid=1 policytype="policy" poluid="4d8dc396-46e3-51ea-7f3f-ee328a5bd07b"
service="HTTPS"trandisp="snat" transip=172.16.200.1 transport=49762 duration=120
sentbyte=0 rcvdbyte=37729 sentpkt=0 rcvpkt=33 appcat="unscanned" wanin=3779 wanout=682
lanin=879 lanout=36005 fwdsrv="fgt-b" utmaction="block" countssl=1 utmref=65506-14
```

Example 3: logging TCP connection failures

In this example, a client initiates a TCP connection to a remote network node through the FortiGate. The connection fails because the IP address or port of the remote node is unreachable. A `Connection Failed` message appears in the logs. In the firewall policy configuration, the `inspection-mode` can be set to either `proxy` or `flow` mode.

Based on the basic FortiGate configuration used in examples 1 and 2, the forward server may need to be removed from the firewall policy if the forward server's TCP IP port is actually reachable. If the forward server proxy tries to set up back-to-back TCP connections with the downstream FortiGate and the remote server as in the case of deep-inspection, then when the client tries to connect to a remote node (even if the IP address or port is unreachable), the downstream FortiGate is able to establish a TCP connection with the upstream forward server, so there will be no `Connection Failed` message in the downstream FortiGate's log.

Currently, the `Connection Failed` message in the downstream FortiGate's log is visible for the case when there is an unreachable TCP port only when explicit web proxy with a proxy policy is configured. Therefore, the following example that makes use of a firewall policy demonstrates this log message is only supported for the unreachable IP address case.

To verify the configuration:

1. Send a HTTP request from the client to an unreachable IP:

```
curl -kv https://172.16.200.34
```

2. On the FortiGate, check the traffic logs:

```
# execute log filter category 3
1: date=2023-04-19 time=20:25:55 eventtime=1681961155100007061 tz="-0700"
logid="0000000013" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.13 srcport=52452 srcintf="port10" srcintfrole="undefined"
dstip=172.16.200.34 dstport=443 dstintf="port9" dstintfrole="undefined"
srccountry="Reserved" dstcountry="Reserved" sessionid=44903 proto=6 action="server-rst"
policyid=1 policytype="policy" poluid="4d8dc396-46e3-51ea-7f3f-ee328a5bd07b"
service="HTTPS" trandisp="snat" transip=172.16.200.1 transport=52452 duration=20
sentbyte=180 rcvdbyte=164 sentpkt=3 rcvdpkt=3 appcat="unscanned" wanin=0 wanout=0
lanin=0 lanout=0 crscore=5 craction=262144 crlevel="low" msg="Connection Failed"
```

Configuring fast fallback for explicit proxy - NEW

The fast fallback (also named "Happy Eyeballs") algorithm, as outlined in [RFC 8305](#), is supported for explicit web proxy. This feature operates by attempting to connect to a web server that is available at multiple IPv4 and IPv6 addresses, either sequentially or simultaneously. As a result, the web server can be connected with reduced user-visible delay, which enhances the overall browsing experience.

```
config web-proxy fast-fallback
  edit <name>
    set status {enable | disable}
    set connection-mode {sequentially | simultaneously}
    set protocol {IPv4-first | IPv6-first | IPv4-only | IPv6-only}
    set connection-timeout <integer>
  next
end
```

`status {enable | disable}` Enable/disable the fast fallback entry (default = enable).

`connection-mode` Set the connection mode for multiple destinations.

- `sequentially`: connect the different destinations sequentially (default).
- `simultaneously`: connect the different destinations simultaneously.

```
protocol {IPv4-first |
        IPv6-first | IPv4-
        only | IPv6-only}
```

Set the connection protocols for multiple destinations.

- `IPv4-first`: connect IPv4 destinations first (default).
- `IPv6-first`: connect IPv6 destinations first.
- `IPv4-only`: connect IPv4 destinations only.
- `IPv6-only`: connect IPv6 destinations only.

```
connection-timeout
    <integer>
```

Start another connection if a connection takes longer than the timeout value, in milliseconds (200 - 1800000, default = 200).

Based on the settings for `connection-mode` and `protocol`, the explicit web proxy will try connecting to the web server in different ways:

- If the `connection-mode` is set to `sequential` (default), then the explicit web proxy will try connecting to the web server by IPv4 first, or by IPv6 first depending on the `protocol` setting. If the connection attempt over IPv4 or IPv6 succeeds, then the connection is kept; but if the connection fails, then it falls back to try a connection over IPv6 or IPv4 instead.
- If the `connection-mode` is set to `simultaneously`, then the explicit web proxy will try connecting to the web server by IPv4 and IPv6 at the same time. If the connection over IPv4 is established first, then the connection is kept for the session and the IPv6 connection is discarded and vice-versa.
- If the user only wants to connect by IPv4 but not IPv6, or by IPv6 but not IPv4, then the `protocol` option can be set to `IPv4-only` or `IPv6-only` accordingly. The explicit web proxy will try connecting to the web server only by IPv4 or IPv6, even though both IPv4 and IPv6 may work.

Example

In this example, a client visits a web server through a FortiGate explicit web proxy that has IPv4 and IPv6 connections to the web server (`www.example.com`), which can resolve to IPv4 address `93.184.216.34` and IPv6 address `2606:2800:220:1:248:1893:25c8:1946`.

The configuration uses sequential connection mode, the IPv4 first protocol, and the default connection timeout (200 ms).

To configure the FortiGate:

1. Configure the IPv4 static route:

```
config router static
    edit 1
        set gateway 172.16.200.251
        set device "port3"
    next
end
```

2. Configure the IPv6 static route:

```
config router static6
    edit 1
        set gateway 2000:172:16:200::254
```

```

        set device "port3"
    next
end

```

3. Configure the proxy destination connection fast fallback:

```

config web-proxy fast-fallback
    edit "ffbk"
        set status enable
        set connection-mode sequentially
        set protocol IPv4-first
        set connection-timeout 200
    next
end

```

4. Configure the exempt URL of the web server from web proxy forwarding and caching:

```

config web-proxy url-match
    edit "ffbk"
        set url-pattern "example.com"
        set fast-fallback "ffbk"
    next
end

```

5. Configure the proxy policy:

```

config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set srcaddr6 "all"
        set dstaddr6 "all"
        set utm-status enable
        set ssl-ssh-profile "deep-custom"
        set av-profile "av"
    next
end

```

Verifying the connection

Scenario 1:

The TCP connection from the explicit web proxy to the web server is established successfully over IPv4 within 200 ms.

As shown in the forward traffic log, the web session data is transmitted over IPv4 between the explicit web proxy and the web server.

```

2: date=2023-06-26 time=18:46:18 eventtime=1687830378260927765 tz="-0700" logid="0000000010"
type="traffic" subtype="forward" level="notice" vd="vdom1" srcip=10.1.100.11 srcport=33304
srcintf="port1" srcintfrole="undefined" dstcountry="United States" srccountry="Reserved"
dstip=93.184.216.34 dstport=80 dstintf="port3" dstintfrole="undefined" sessionid=1688881487
service="HTTP" proxyapptype="web-proxy" proto=6 action="accept" policyid=1

```

```
policytype="proxy-policy" poluid="560d8520-fa7b-51ed-e06a-df05ec145542" trandisp="snat"
transip=0.0.0.0 transport=0 duration=0 wanin=0 rcvdbyte=0 wanout=0 lanin=131 sentbyte=131
lanout=1591 appcat="unscanned"
```

Scenario 2:

The TCP connection from the explicit web proxy to the web server is not established over IPv4 within 200 ms and falls back to IPv6 successfully.

The IPv4 path to the server is interrupted, and the TCP connection between the explicit web proxy and web server cannot be established. The explicit web proxy waits until the 200 ms connection timeout timer expires, then attempts to connect to the server by IPv6, which is successful. The web session data is transmitted over IPv6, as shown in the forward traffic log.

```
2: date=2023-06-26 time=18:47:27 eventtime=1687830447277653089 tz="-0700" logid="0000000010"
type="traffic" subtype="forward" level="notice" vd="vdom1" srcip=10.1.100.11 srcport=36636
srcintf="port1" srcintfrole="undefined" dstcountry="United States" srccountry="Reserved"
dstip=2606:2800:220:1:248:1893:25c8:1946 dstport=80 dstintf="port3" dstintfrole="undefined"
sessionid=1688881488 service="HTTP" proxyapptype="web-proxy" proto=6 action="accept"
policyid=1 policytype="proxy-policy" poluid="560d8520-fa7b-51ed-e06a-df05ec145542"
trandisp="snat" transport=0 duration=1 wanin=0 rcvdbyte=0 wanout=0 lanin=131 sentbyte=131
lanout=1591 appcat="unscanned"
```

Forward HTTPS requests to a web server without the need for an HTTP CONNECT message - NEW

An explicit web proxy can forward HTTPS requests to a web server without the need for an HTTP CONNECT message. The FortiGate explicit web proxy can be configured to detect the HTTPS scheme in the request line of a plain text HTTP request and forward it as an HTTPS request to the web server. This allows applications that cannot use the CONNECT message for sending an HTTPS request to communicate with the web server through an explicit web proxy.

```
config firewall proxy-policy
    edit <id>
        set detect-https-in-http-request {enable | disable}
    next
end
```

Example

Based on the following topology, an HTTPS request is sent to a web server through an explicit web proxy.

To enable detection of HTTPS in an HTTP request:

1. Configure the explicit web proxy:

```
config web-proxy explicit
    set status enable
```

```

        set ftp-over-http enable
        set socks enable
        set http-incoming-port 8080
        set ipv6-status enable
        set unknown-http-version best-effort
    end

```

2. Enable the explicit web proxy on port1:

```

config system interface
    edit "port1"
        set ip 10.1.100.2 255.255.255.0
        set explicit-web-proxy enable
    next
end

```

3. Configure the proxy policy:

```

config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set utm-status enable
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
        set detect-https-in-http-request enable
    next
end

```

An SSL-SSH profile with deep inspection must be applied in order to decrypt the server response in HTTPS and forward the response to the client by HTTP.

4. Using Telnet, send an HTTP request with an HTTPS scheme as follows:

```

telnet 10.1.100.2 8080
Trying 10.1.100.2...
Connected to 10.1.100.2.
Escape character is '^]'.
POST https://172.16.200.33/ HTTP/1.1
Host: 172.16.200.33
User-Agent: curl/7.68.0
Accept: */*
Content-Type: application/x-www-form-urlencoded
Content-Length: 0

HTTP/1.1 200 OK

```

5. Verify the traffic log. The HTTP request is forwarded to the server successfully by HTTPS:

```
# execute log filter category 3
...
2: date=2023-07-31 time=16:02:22 eventtime=1690844541296891542 tz="-0700"
logid="0000000010" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=46074 srcintf="port1" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=172.16.200.33 dstport=443
dstintf="port3" dstintfrole="undefined" sessionid=1799884153 service="HTTPS"
proxyapptype="web-proxy" proto=6 action="accept" policyid=1 policytype="proxy-policy"
poluid="73379360-2d21-51ee-77d8-154efc517a6a" trandisp="snat" transip=172.16.200.2
transport=2713 duration=4 wanin=3053 rcvbyte=3053 wanout=757 lanin=169 sentbyte=169
lanout=279 appcat="unscanned"
```

DHCP servers and relays

A DHCP server dynamically assigns IP addresses to hosts on the network connected to the interface. The host computers must be configured to obtain their IP addresses using DHCP. You can configure one or more DHCP servers on any FortiGate interface.

A DHCP server can be in server or relay mode. In server mode, you can define up to ten address ranges to assign addresses from, and options such as the default gateway, DNS server, lease time, and other advanced settings. In relay mode, the interface forwards DHCP requests from DHCP clients to an external DHCP server and returns the responses to the DHCP clients. The DHCP server must have appropriate routing so that its response packets to the DHCP clients arrive at the unit.

If an interface is connected to multiple networks through routers, you can add a DHCP server for each network. The IP range of each DHCP server must match the network address range. The routers must be configured for DHCP relay.

Default DHCP server for low-end FortiGates

On low-end FortiGate units, a DHCP server is configured on the internal interface, by default, with the following values:

Field	Value
Address Range	192.168.1.110 to 192.168.1.210
Netmask	255.255.255.0
Default Gateway	192.168.1.99
Lease Time	7 days
DNS Server 1	192.168.1.99

These settings are appropriate for the default internal interface IP address of 192.168.1.99. If you change this address to a different network, you need to change the DHCP server settings to match.

- [DHCP options on page 388](#)
- [DHCP addressing mode on an interface on page 395](#)
- [VCI pattern matching for DHCP assignment on page 398](#)
- [DHCP shared subnet on page 400](#)

- [DHCP smart relay on interfaces with a secondary IP on page 401](#)
- [FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses on page 403](#)

Basic configuration

The following contains information on basic configurations.

Configure a DHCP server on an interface

A DHCP server can be configured on an interface in the GUI from *Network > Interfaces*.

To configure a DHCP server in the GUI:

1. Go to *Network > Interfaces*.
2. Edit an interface.
3. Enable the *DHCP Server* option and configure the settings.
4. Click *OK*.

Field	Description
Address Range	By default, the FortiGate unit assigns an address range based on the address of the interface for the complete scope of the address. For example, if the interface address is 172.20.120.230, the default range created is 172.20.120.231 to 172.20.120.254. Select the range and select <i>Edit</i> to adjust the range or select <i>Create New</i> to add a different range.
Netmask	Enter the netmask of the addresses that the DHCP server assigns.
Default Gateway	Select this to use either <i>Same as Interface IP</i> or select <i>Specify</i> and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
DNS Server	Select this to use <i>Same as system DNS</i> , <i>Same as Interface IP</i> or select <i>Specify</i> and enter the IP address of the DNS server.
Mode	Select the type of DHCP server FortiGate will be. By default, it is a <i>Server</i> . Select <i>Relay</i> if needed. When <i>Relay</i> is selected, the above configuration is replaced by a field to enter the <i>DHCP Server IP</i> address.
DHCP Server IP	This appears only when <i>Mode</i> is <i>Relay</i> . Enter the IP address of the DHCP server where FortiGate obtains the requested IP address.
Type	Select this to use the DHCP in <i>Regular</i> or <i>IPsec</i> mode.
Additional DHCP Options	Use this to create new DHCP options.
Add from DHCP Client List	If the client is currently connected and using an IP address from the DHCP server, you can select this option to select the client from the list.

To configure a DHCP server in the CLI:

```

config system dhcp server
    edit 1
        set dns-service default
        set default-gateway 192.168.1.2
        set netmask 255.255.255.0
        set interface "port1"
        config ip-range
            edit 1
                set start-ip 192.168.1.1
                set end-ip 192.168.1.1
            next
            edit 2
                set start-ip 192.168.1.3
                set end-ip 192.168.1.254
            next
        end
        set timezone-option default
        set tftp-server "172.16.1.2"
    next
end

```

Configure a DHCP relay on an interface**To configure a DHCP relay in the GUI:**

1. Go to *Network > Interfaces*.
2. Edit an interface.
3. Expand the *Advanced* section and set *Mode* to *Relay*.
4. Enter the *DHCP Server IP*.
5. Click *OK*.

To configure a DHCP relay in the CLI:

1. Configure the interface, making sure to configure `set dhcp-relay-ip`:

```

config system interface
    edit "port2"
        set vdom "root"
        set dhcp-relay-service enable
        set ip 10.1.1.5 255.255.255.0
        set allowaccess ping https ssh fabric
        set type physical
        set snmp-index 4
        set dhcp-relay-ip "192.168.20.10"
    next
end

```

Configure a DHCP server and relay on an interface

A FortiGate interface can be configured to work in DHCP server mode to lease out addresses, and at the same time relay the DHCP packets to another device, such as a FortiNAC to perform device profiling.

The DHCP message to be forwarded to the relay server under the following conditions:

- `dhcp-relay-request-all-server` is enabled
- Message type is either DHCPDISCOVER or DHCPINFORM
- Client IP address in client message is 0
- Server ID is NULL in the client message
- Server address is a broadcast address (255.255.255.255)
- Server address is 0

Configuring a DHCP server and relay on the same interface is currently only supported in the CLI.

To configure a DHCP server and relay in the CLI:

1. Configure the interface:

```
config system interface
    edit "port2"
        set vdom "root"
        set dhcp-relay-service enable
        set ip 10.1.1.5 255.255.255.0
        set allowaccess ping https ssh fabric
        set type physical
        set snmp-index 4
        set dhcp-relay-ip "192.168.20.10"
        set dhcp-relay-request-all-server enable
    next
end
```

2. Configure the DHCP server settings:

```
config system dhcp server
    edit 17
        set status enable
        set dns-service default
        set default-gateway 10.1.1.5
        set netmask 255.255.255.0
        set interface "port2"
        config ip-range
            edit 1
                set start-ip 10.1.1.6
                set end-ip 10.1.1.254
            next
        end
    next
end
```

Excluding addresses in DHCP

If you have a large address range for the DHCP server, you can block a range of addresses that will not be included in the available addresses for the connecting users using the `config exclude-range` subcommand.

To exclude addresses in DHCP:

```
config system dhcp server
  edit <id>
    config exclude-range
      edit <sequence_number>
        set start-ip <address>
        set end-ip <address>
      next
    end
  next
end
```

Viewing information about DHCP server connections

To view information about DHCP server connections, go to *Dashboard > Network* and expand the *DHCP* monitor widget. On this page, you can also add IP addresses to the reserved IP address list.

DHCP options

When adding a DHCP server, you can include DHCP options. The DHCP options are BOOTP vendor information fields that provide additional vendor-independent configuration parameters to manage the DHCP server. For example, you might need to configure a FortiGate DHCP server that gives out a separate option as well as an IP address, such as an environment that needs to support PXE boot with Windows images. The *Option code* is specific to the application. The documentation for the application indicates the values to use. The *Option code* is a value between 1 and 255.

For detailed information about DHCP options, see [RFC 2132](#), DHCP Options and BOOTP Vendor Extensions.

The FortiOS DHCP server supports up to a maximum of 30 options per DHCP server. These optional fields can be set in either the GUI or CLI.

DHCP server options are not available in transparent mode.

The DHCP options include:

- [Common DHCP options on page 388](#)
- [Additional DHCP options on page 391](#)
- [IP address assignment with relay agent information option on page 393](#)

Common DHCP options

All FortiGate models come with predefined DHCP options. These DHCP options are widely used and required in most scenarios. The following DHCP options can be set straight from the *DHCP server* section of the *Edit Interface* dialog:

Option Code	Option Name	Purpose
*1	<i>Netmask</i>	Assign subnet mask to the DHCP client.

Option Code	Option Name	Purpose
*3	<i>Default Gateway</i>	Assign default gateway to the DHCP client.
6	<i>DNS server</i>	Assign DNS server to the DHCP client.
42	<i>NTP server</i>	Assign NTP server to the DHCP client.
*51	<i>Lease time</i>	Lease time for the DHCP client.
138	<i>Wireless controllers</i>	Assign CAPWAP Access Controller addresses to the DHCP client.
150	<i>TFTP server(s)</i>	Assign TFTP server to the DHCP client.

The parameter marked with an asterisk (*) are mandatory and must be filled in.

Configuring the lease time

This configuration implements DHCP option code 51. The global lease time (measured in seconds, 300 - 864000) determines the length of time an IP address remains assigned to a client. Once the lease expires, the address is released for allocation to the next client that requests an IP address.

To configure the global lease time:

```
config system dhcp server
    edit <id>
        set interface <interface>
        set netmask <netmask>
        set lease-time <integer>
    next
end
```

The default lease time is seven days (604800 seconds). To have an unlimited lease time, set the value to zero.

The lease time can also be configured in the GUI in the *Lease time* field within the *DHCP server* section of the *Edit Interface* dialog.

Configuring the lease time for IP ranges

The lease time can be also be configured for an IP range. Measured in seconds, the range is similar to the global lease time (300 - 864000), but the default value is zero (0). If the default (0) is used for an IP range, it applies the global DHCP server lease time value.

To configure the lease time for an IP range:

```
config system dhcp server
    edit <id>
        config ip-range
            edit <id>
                set lease-time <integer>
            next
        end
    next
end
```

This setting can only be configured in the CLI.

Breaking an address lease

If you need to end an IP address lease, you can break the lease. This is useful if you have limited addresses and longer lease times when some leases are no longer necessary, for example, with corporate visitors.

To break a lease:

```
# execute dhcp lease-clear <ip_address>
```

To break a lease for all IP addresses for the DHCP servers in the current VDOM:

```
# execute dhcp lease-clear all
```

Configuring NTP servers

This configuration implements DHCP option code 42. NTP server can be used by the client to synchronize their time which is very important as for many features to work, including scheduling, logging, and SSL-dependent features, the FortiOS system time must be accurate. This option specifies a list of the NTP servers available to the client by IP address.

To configure NTP servers:

```
config system dhcp server
  edit 2
    set ntp-service {local | default | specify}
    set ntp-server1 <class_ip>
    set ntp-server2 <class_ip>
    set ntp-server3 <class_ip>
  next
end
```

NTP servers can also be configured in the GUI in the *NTP server* field within the *DHCP server > Advanced* section of the *Edit Interface* dialog.

```
ntp-service {local |
default | specify}
```

Set the option for assigning NTP servers to DHCP clients:

- **local:** the IP address of the interface that the DHCP server is added to becomes the client's NTP server IP address.
- **default:** clients are assigned the FortiGate's configured NTP servers.
- **specify:** specify up to three NTP servers in the DHCP server configuration.

Configuring TFTP servers

This configuration implements DHCP option code 150. TFTP server are used by VoIP phones to obtain the VoIP Configuration. You can configure multiple TFTP servers for a DHCP server. For example, you may want to configure a main TFTP server and a backup TFTP server.

The `tftp-server` command allows you to configure the TFTP servers, using either their hostnames or IP addresses. Separate multiple server entries with spaces.

To configure TFTP servers:

```
config system dhcp server
    edit <id>
        set interface <interface>
        set netmask <netmask>
        set tftp-server <hostname/IP address> <hostname/IP address>
    next
end
```

TFTP servers can also be configured in the GUI in the *TFTP server(s)* field within the *DHCP server > Advanced* section of the *Edit Interface* dialog.

Additional DHCP options

The FortiGate can be used to provide additional DHCP options that can be useful for different scenarios.

A few of the options are explained below:

- [Option 82 on page 392](#)
- [Option 77 on page 393](#)

To configure the DHCP options in the GUI:

1. Go to *Network > Interfaces*, click *Create New* or *Edit* the existing interface.
2. Enable *DHCP Server*.
3. Expand the *Advanced* section and select *Create New* under *Additional DHCP options*.
4. Select a predefined *Option code* from the list or select *Specify* to enter a custom *Option code*.
5. Configure the rest of the parameters as required and click *OK* to save the options.
6. Click *OK* to save the setting.

To configure the DHCP options in the CLI:

```
config system dhcp server
    edit <id>
        config options
            edit <integer>
                set code <integer>
                set type {hex | string | ip | fqdn}
                set value <string>
            next
        end
    next
end
```

Variable	Description
code <integer>	DHCP client option code (0 - 255, default = 0). See Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) Parameters for a list of possible options.
type {hex string ip}	DHCP server option type (default = hex).

Variable	Description
fqdn}	
value <string>	DHCP server option value.
ip <ip address>	DHCP server option IP address. This option is only available when type is ip.

Example

To configure option 252 with value `http://192.168.1.1/wpad.dat`:

```
config system dhcp server
    edit <id>
        config options
            edit <id>
                set code 252
                set type hex
                set value 687474703a2f2f3139322e3136382e312e312f777061642e646174
            next
        end
    next
end
```

In the example above, `687474703a2f2f3139322e3136382e312e312f777061642e646174` is the hexadecimal equivalent of the ASCII text `http://192.168.1.1/wpad.dat`.

Option 82

The DHCP relay agent information option (option 82 in [RFC 3046](#)) helps protect the FortiGate against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation.

This option is disabled by default. However, when `dhcp-relay-service` is enabled, `dhcp-relay-agent-option` becomes enabled.

To configure the DHCP relay agent option:

```
config system interface
    edit <interface>
        set vdom root
        set dhcp-relay-service enable
        set dhcp-relay-ip <ip>
        set dhcp-relay-agent-option enable
        set vlanid <id>
    next
end
```

See [IP address assignment with relay agent information option on page 393](#) for an example.

Option 77

This option can be used for User Class information (UCI) matching. When enabled, only DHCP requests with a matching UCI are served with the specified range.

To configure UCI matching:

```
config system dhcp server
  edit <id>
    config ip-range
      edit <id>
        set uci-match {enable | disable}
        set uci-string <string>
      next
    end
  config options
    edit <id>
      set uci-match {enable | disable}
      set uci-string <string>
    next
  end
next
end
```

<code>uci-match {enable disable}</code>	Enable/disable User Class information (UCI) matching for option 77.
<code>uci-string <string></code>	Enter one or more UCI strings in quotation marks separated by spaces.

IP address assignment with relay agent information option

Option 82 (DHCP relay information option) helps protect the FortiGate against attacks such as spoofing (or forging) of IP and MAC addresses, and DHCP IP address starvation.

The following CLI variables are included in the `config system dhcp server > config reserved-address` command:

<code>circuit-id-type {hex string}</code>	DHCP option type; hex or string (default).
<code>circuit-id <value></code>	Option 82 circuit ID of the client that will get the reserved IP address. Format: <i>vlan-mod-port</i> <ul style="list-style-type: none"> vlan: VLAN ID (2 bytes) mod: 1 = snoop, 0 = relay (1 byte) port: port number (1 byte)

remote-id-type {hex string}	DHCP option type; hex or string (default).
remote-id <value>	Option 82 remote ID of the client that will get the reserved IP address. Format: the MAC address of the client.
type {mac option82}	The DHCP reserved address type; mac (default) or option82.

To create an IP address assignment rule using option 82 in the GUI:

1. Go to *Network > Interfaces*.
2. Edit an existing port, or create a new one.

The port *Role* must be *LAN* or *Undefined*.

3. Enable *DHCP Server*.
4. Configure the address ranges and other settings as needed.
5. Click + to expand the *Advanced* options.

Edit Interface

DHCP Server

DHCP status: Enabled Disabled

Address range: 192.168.2.100-192.168.2.254

Netmask: 255.255.255.0

Default gateway: Same as Interface IP Specify

DNS server: Same as System DNS Same as Interface IP Specify

Lease time: 604800 seconds(s)

Advanced

Mode: Server Relay

Type: Regular IPsec

NTP server: Local Same as System NTP Specify

Wireless controllers: Same as Interface IP Specify

Time zone: Same as System Specify

Next bootstrap server: 0.0.0.0

TFTP server(s):

IP Address Assignment Rules

+ Create New Edit Delete Search Add from DHCP Client List

Type	Match Criteria	Action	IP
Implicit	Unknown MAC Addresses	Assign IP	

6. In the *IP Address Assignment Rules* table, click *Create New*. The *Create New IP Address Assignment Rule* pane opens.
7. Configure the new rule:
 - a. For the *Type*, select *DHCP Relay Agent*.
 - b. Enter the *Circuit ID* and *Remote ID*.
 - c. Enter the *IP* address that will be reserved.

Create New IP Address Assignment Rule

Type: **MAC Address** **DHCP Relay Agent**

Description: Write a comment... 0/255

Match Criteria

Circuit ID: String **Hexadecimal** 00010102

Remote ID: String **Hexadecimal** 704ca5e477d6

Action

Action type: **Assign IP** **Block** **Reserve IP**

IP: 192.168.2.100

OK Cancel

8. Click OK.

To create an IP address assignment rule using option 82 with the CLI:

```
config system dhcp server
  edit 1
    set netmask 255.255.255.0
    set interface "port4"
    config ip-range
      edit 1
        set start-ip 192.168.2.100
        set end-ip 192.168.2.254
      next
    end
    config reserved-address
      edit 1
        set type option82
        set ip 192.168.2.100
        set circuit-id-type hex
        set circuit-id "00010102"
        set remote-id-type hex
        set remote-id "704ca5e477d6"
      next
    end
  next
end
```

DHCP addressing mode on an interface

Any FortiGate interface can be configured to obtain an IP address dynamically using DHCP. If you configure DHCP on an interface on the FortiGate, the FortiGate automatically broadcasts a DHCP request from the interface. The interface is configured with the IP address, any DNS server addresses, and the default gateway address that the DHCP server provides.

Configuring an Interface as a DHCP Client

You can configure interface as a DHCP client.

To configure an interface as a DHCP client in the GUI:

1. Go to *Network > Interfaces*.
2. Edit an interface.
3. Select the *DHCP* option in the *Addressing mode*.
4. Configure the rest of the setting as required.
5. Click *OK*.

The following table describes the DHCP status information when DHCP is configured for an interface.

Field	Description
Status	Displays DHCP status messages as the interface connects to the DHCP server and gets addressing information. Status can be one of the following values: <ul style="list-style-type: none"> • <i>Initializing</i>: No activity. • <i>Connecting</i>: Interface attempts to connect to the DHCP server. • <i>Connected</i>: Interface retrieves an IP address, netmask, and other settings from the DHCP server. • <i>Failed</i>: Interface was unable to retrieve an IP address and other settings from the DHCP server.
Obtained IP/Netmask	The IP address and netmask leased from the DHCP server. This is only displayed if the <i>Status</i> is <i>Connected</i> .
Renew	Select this to renew the DHCP license for this interface. This is only displayed if the <i>Status</i> is <i>Connected</i> .
Expiry Date	The time and date when the leased IP address and netmask is no longer valid for the interface. The IP address is returned to the pool to be allocated to the next user request for an IP address. This is only displayed if the <i>Status</i> is <i>Connected</i> .
Default Gateway	The IP address of the gateway defined by the DHCP server. This is displayed only if the <i>Status</i> is <i>Connected</i> , and if <i>Retrieve default gateway from server</i> is enabled.
Acquired DNS	The DNS server IP defined by the DHCP server. This is displayed only if the <i>Status</i> is <i>Connected</i> .
Retrieve default gateway from server	Enable this to retrieve a default gateway IP address from the DHCP server. The default gateway is added to the static routing table.
Distance	Enter the administrative distance for the default gateway retrieved from the DHCP server. The administrative distance is an integer from 1 to 255, and specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route.
Override internal DNS	Enable this to use the DNS addresses retrieved from the DHCP server instead of the DNS server IP addresses on the DNS page. When VDOMs are enabled, you can override the internal DNS only on the management VDOM.

To configure an interface as a DHCP client in the CLI:

```
config system interface
  edit <name>
    set mode dhcp
    set defaultgw {enable | disable}
    set distance <integer>
    set dns-server-override {enable | disable}
  next
end
```

Configuring the DHCP renew time

You can set a minimum DHCP renew time for an interface acting as a DHCP client. This option is available only when mode is set to DHCP.

To set the DHCP renew time:

```
config system interface
  edit <name>
    set vdom <vdom>
    set interface <interface>
    set mode dhcp
    set dhcp-renew-time <integer>
  next
end
```

The possible values for `dhcp-renew-time` are 300 to 605800 seconds (five minutes to seven days). To use the renew time that the server provides, set this entry to 0.

DHCP client options

When an interface is in DHCP addressing mode, DHCP client options can be configured in the CLI. For example, a vendor class identifier (usually DHCP client option 60) can be specified so that a request can be matched by a specific DHCP offer.

Multiple options can be configured, but any options not recognized by the DHCP server are discarded.

To configure client option 60 - vendor class identifier:

```
config system interface
  edit port1
    set vdom vdom1
    set mode dhcp
    config client-options
      edit 1
        set code 60
        set type hex
        set value aabbccdd
      next
    end
    set type physical
    set snmp-index 4
```

```

    next
end

```

Variable	Description
code <integer>	DHCP client option code (0 - 255, default = 0). See Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) Parameters for a list of possible options.
type {hex string ip fqdn}	DHCP client option type (default = hex).
value <string>	DHCP client option value.
ip <ip>	DHCP client option IP address. This option is only available when type is ip.

VCI pattern matching for DHCP assignment

VCIs (vendor class identifiers) are supported in DHCP to allow VCI pattern matching as a condition for IP or DHCP option assignment. A single IP address, IP ranges of a pool, and dedicated DHCP options can be mapped to a specific VCI string.

```

config system dhcp server
    edit <id>
        config ip-range
            edit <id>
                set vci-match {enable | disable}
                set vci-string <string>
            next
        end
        config options
            edit <id>
                set vci-match {enable | disable}
                set vci-string <string>
            next
        end
    next
end

```

vci-match {enable disable}	Enable/disable VCI matching. When enabled, only DHCP requests with a matching VCI are served with this range.
vci-string <string>	Set the VCI string. Enter one or more VCI strings in quotation marks separated by spaces.

Example

In this example, any DHCP client that matches the FortiGate-201F VCI will get their IP from the pool of 10.2.2.133-10.2.2.133, and options 42 (NTP servers) and 150 (TFTP server address). Any DHCP client that matches the FortiGate-101F VCI will get their IP from the default pool (10.2.2.132-10.2.2.132/10.2.2.134-10.2.2.254) and only get the 150 option.

**To configure VCI pattern matching on FortiGate A:**

```
config system dhcp server
  edit 1
    set dns-service default
    set default-gateway 10.2.2.131
    set netmask 255.255.255.0
    set interface "port3"
    config ip-range
      edit 1
        set start-ip 10.2.2.132
        set end-ip 10.2.2.132
      next
      edit 2
        set start-ip 10.2.2.133
        set end-ip 10.2.2.133
        set vci-match enable
        set vci-string "FortiGate-201F"
      next
      edit 3
        set start-ip 10.2.2.134
        set end-ip 10.2.2.254
      next
    end
    config options
      edit 1
        set code 42
        set type ip
        set vci-match enable
        set vci-string "FortiGate-201F"
        set ip "8.8.8.8"
      next
      edit 2
        set code 150
        set type ip
        set ip "172.16.200.55"
      next
    end
    set vci-match enable
    set vci-string "FortiGate-201F" "FortiGate-101F"
  next
end
```

DHCP shared subnet

A FortiGate can act as a DHCP server and assign IP addresses from different subnets to clients on the same interface or VLAN based on the requests coming from the same DHCP relay agent. A FortiGate may have more than one server and pool associated with the relay agent, and it can assign IP addresses from the next server when the current one is exhausted. This way, the FortiGate can allocate IP addresses more efficiently and avoid wasting unused addresses in each subnet.

```
config system dhcp server
  edit <id>
    set shared-subnet {enable | disable}
    set relay-agent <ip_address>
  next
end
```

Example

In this example, there are two DHCP servers configured on the FortiGate. The first two clients (1 and 2) get their IP from the DHCP server 1. Once the DHCP server 1's IP pool is exhausted, subsequent clients (3 and 4) get their IP from DHCP server 2.

To configure a DHCP shared subnet:

1. Configure the DHCP servers:

```
config system dhcp server
  edit 1
    set default-gateway 10.18.0.10
    set netmask 255.255.255.0
    set interface "p2_vl3819"
    config ip-range
      edit 1
        set start-ip 10.18.0.110
        set end-ip 10.18.0.111
      next
    end
    set shared-subnet enable
    set relay-agent 10.18.0.10
  next
end
```

```

        set dns-server1 8.8.8.8
    next
    edit 2
        set default-gateway 10.18.1.130
        set netmask 255.255.255.128
        set interface "p2_vl3819"
        config ip-range
            edit 1
                set start-ip 10.18.1.200
                set end-ip 10.18.1.201
            next
        end
        set shared-subnet enable
        set relay-agent 10.18.0.10
        set dns-server1 8.8.8.8
    next
end

```

2. Verify the DHCP lease list:

```

# execute dhcp lease-list
port6

```

IP	MAC-Address	Hostname	VCI	SSID	AP	SERVER-ID	Expiry
10.18.0.110	00:50:56:02:92:11					1	Fri Jan 13 15:37:35 2023
10.18.0.111	00:50:56:02:92:12					1	Fri Jan 13 15:37:38 2023

Result: PASS

Clients 1 and 2 get their IP from the DHCP server 1.

When the IP pool is exhausted, the DHCP daemon assigns the IP from other pools that have the same relay agent.

3. Verify the DHCP lease list:

```

# execute dhcp lease-list
port6

```

IP	MAC-Address	Hostname	VCI	SSID	AP	SERVER-ID	Expiry
10.18.0.110	00:50:56:02:92:11					1	Fri Jan 13 15:37:35 2023
10.18.0.111	00:50:56:02:92:12					1	Fri Jan 13 15:37:38 2023
10.18.1.200	00:50:56:02:92:13					2	Fri Jan 13 15:38:05 2023
10.18.1.201	00:50:56:02:92:14					2	Fri Jan 13 15:38:06 2023

Clients 3 and 4 get their IP from DHCP server 2, since the server 1 IP pool is exhausted.

DHCP smart relay on interfaces with a secondary IP

DHCP relays can be configured on interfaces with secondary IP addresses. The FortiGate will track the number of unanswered DHCP requests for a client on the interface's primary IP. After three unanswered DHCP requests, the FortiGate will forward DHCP requests to DHCP relays configured under the secondary IP using the secondary IP address as the source. After three unanswered DHCP requests, the FortiGate will return to using the primary IP and restart the process.

```

config system interface
    edit <name>
        set dhcp-smart-relay {enable | disable}
        config secondaryip
            edit <id>
                set secip-relay-ip <secondary_dhcp_relay_IP_1> <secondary_dhcp_relay_IP_2>
            next
        end
    next
end

```

DHCP relay targets under both the primary and secondary IP may be the same or unique. If smart relay is not configured, all requests are forwarded using the primary IP address on the interface.

Example

In this example, DHCP smart relay is configured on port5 with a DHCP relay IP address of 10.2.2.1.

To configure DHCP smart relay on interfaces with a secondary IP:

1. Configure DHCP relay on the interfaces:

```

config system interface
    edit "port3"
        set vdom "vdom1"
        set ip 10.2.2.2 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set snmp-index 5
    next
    edit "port5"
        set vdom "vdom1"
        set dhcp-relay-service enable
        set dhcp-smart-relay enable
        set ip 5.2.2.1 255.255.255.0
        set allowaccess ping https ssh snmp http
        set type physical
        set snmp-index 7
        set secondary-IP enable
        set dhcp-relay-ip "10.2.2.1"
        config secondaryip
            edit 1
                set ip 11.2.2.1 255.255.255.0
                set secip-relay-ip "10.2.2.1"
                set allowaccess ping https ssh snmp http
            next
        end
    next
end

```

2. Verify the debug messages to check that the DHCP relay is working. After three unanswered DHCP requests, the request is forwarded to the secondary IP DHCP relay target:

```
# diagnose debug application dhcprelay -1
Debug messages will be on for 30 minutes.

(xid:7ea80e4b) received request message from 0.0.0.0:68 to 255.255.255.255 at port5
(xid:7ea80e4b) got a DHCPDISCOVER

(xid:7ea80e4b) received request message from 10.2.2.1:67 to 11.2.2.1 at port3
(xid:7ea80e4b) got a DHCPACK
(xid:7ea80e4b) from server 10.2.2.1
(xid:7ea80e4b) sending dhcp reply from 11.2.2.1:67 to 255.255.255.255:68
```

FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses

As clients are assigned IP addresses, they send back information that would be found in an A record to the FortiGate DHCP server, which can take this information and pass it back to a corporate DNS server so that even devices using leased IP address can be reached using FQDNs. You can configure the settings for this feature using the `ddns-update` CLI command and some other DDNS related options. Please refer to *DDNS update override* in the [DDNS on page 276](#) topic for further details.

Static routing

Static routing is one of the foundations of firewall configuration. It is a form of routing in which a device uses manually-configured routes. In the most basic setup, a firewall will have a default route to its gateway to provide network access. In

a more complex setup with dynamic routing, ADVPN, or SD-WAN involved, you would still likely find static routes being deployed.

This section explores concepts in using static routing and provides examples in common use cases:

- [Routing concepts on page 404](#)
- [Policy routes on page 418](#)
- [Equal cost multi-path on page 421](#)

Default route

The default route has a destination of `0.0.0.0/0.0.0.0`, representing the least specific route in the routing table. It is a catch all route in the routing table when traffic cannot match a more specific route. Typically this is configured with a static route with an administrative distance of `10`. In most instances, you will configure the next hop interface and the gateway address pointing to your next hop. If your FortiGate is sitting at the edge of the network, your next hop will be your ISP gateway. This provides internet access for your network.

Sometimes the default route is configured through DHCP. On some desktop models, the WAN interface is preconfigured in DHCP mode. Once the WAN interface is plugged into the network modem, it will receive an IP address, default gateway, and DNS server. FortiGate will add this default route to the routing table with a distance of `5`, by default. This will take precedence over any default static route with a distance of `10`. Therefore, take caution when you are configuring an interface in DHCP mode, where *Retrieve default gateway from server* is enabled. You may disable it and/or change the distance from the *Network > Interfaces* page when you edit an interface.

Adding or editing a static route

To add a static route using the GUI:

1. Go to *Network > Static Routes* and click *Create New*.
2. Enter the following information:

Dynamic Gateway	When enabled, a selected DHCP/PPPoE interface will automatically retrieve its dynamic gateway.
Destination	<ul style="list-style-type: none"> • Subnet Enter the destination IP address and netmask. A value of <code>0.0.0.0/0.0.0.0</code> creates a default route. • Named Address Select an address or address group object. Only addresses with static route configuration enabled will appear on the list. This means a geography type address cannot be used. • Internet Service Select an Internet Service. These are known IP addresses of popular services across the Internet.
Interface	Select the name of the interface that the static route will connect through.
Gateway Address	Enter the gateway IP address. When selecting an IPsec VPN interface or SD-WAN creating a blackhole route, the gateway cannot be specified.
Administrative Distance	Enter the distance value, which will affect which routes are selected first by different protocols for route management or load balancing. The default is <code>10</code> .
Advanced Options	Optionally, expand <i>Advanced Options</i> and enter a <i>Priority</i> . When two routes have an equal distance, the route with a lower priority number will take precedence. The default is <code>1</code> .

3. Click *OK*.

Configuring FQDNs as a destination address in static routes

You can configure FQDN firewall addresses as destination addresses in a static route, using either the GUI or the CLI.

In the GUI, to add an FQDN firewall address to a static route in the firewall address configuration, enable the *Static Route Configuration* option. Then, when you configure the static route, set *Destination* to *Named Address*.

To configure an FQDN as a destination address in a static route using the CLI:

```
config firewall address
    edit 'Fortinet-Documentation-Website'
        set type fqdn
        set fqdn docs.fortinet.com
        set allow-routing enable
    next
end

config router static
    edit 0
        set dstaddr Fortinet-Documentation-Website
        ...
    next
end
```

Routing table

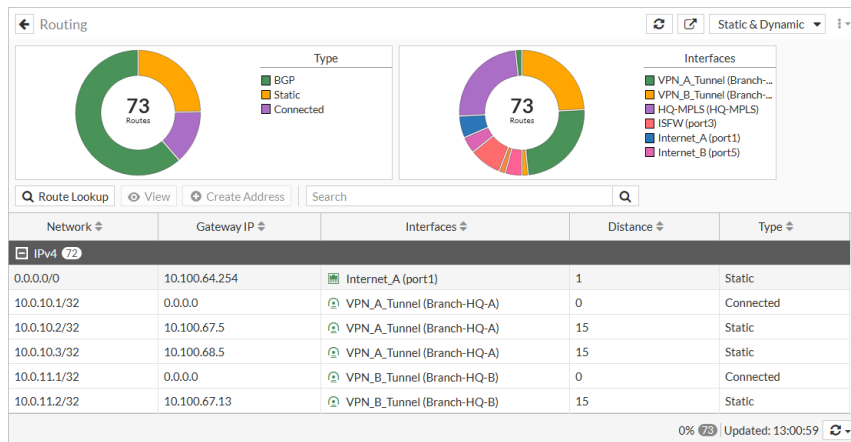

A routing table consists of only the best routes learned from the different routing protocols. The most specific route always takes precedence. If there is a tie, then the route with a lower administrative distance will be injected into the routing table. If administrative distances are also equal, then all the routes are injected into the routing table, and *Cost* and *Priority* become the deciding factors on which a route is preferred. If these are also equal, then FortiGate will use [Equal cost multi-path on page 421](#) to distribute traffic between these routes.

Viewing the routing table in the GUI

You can view routing tables in the FortiGate GUI under *Dashboard > Network > Static & Dynamic Routing* by default. Expand the widget to see the full page. Additionally, if you want to convert the widget into a dashboard, click on the *Save as Monitor* icon on the top right of the page.

You can also monitor policy routes by toggling from *Static & Dynamic* to *Policy* on the top right corner of the page. The active policy routes include policy routes that you created, SD-WAN rules, and Internet Service static routes. It also supports downstream devices in the Security Fabric.

The following figure shows an example of the static and dynamic routes in the Routing Monitor:

To view more columns, right-click on the column header to select the columns to be displayed:

Field	Description
IP Version	Shows whether the route is IPv4 or IPv6.
Network	The IP addresses and network masks of destination networks that the FortiGate can reach.
Gateway IP	The IP addresses of gateways to the destination networks.
Interfaces	The interface through which packets are forwarded to the gateway of the destination network.
Distance	The administrative distance associated with the route. A lower value means the route is preferable compared to other routes to the same destination.
Type	<p>The type values assigned to FortiGate routes (Static, Connected, RIP, OSPF, or BGP):</p> <ul style="list-style-type: none"> Connected: All routes associated with direct connections to FortiGate interfaces Static: The static routes that have been added to the routing table manually RIP: All routes learned through RIP RIPNG: All routes learned through RIP version 6 (which enables the sharing of routes through IPv6 networks) BGP: All routes learned through BGP OSPF: All routes learned through OSPF OSPF6: All routes learned through OSPF version 6 (which enables the sharing of routes through IPv6 networks) IS-IS: All routes learned through IS-IS HA: RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you're viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster.
Metric	<p>The metric associated with the route type. The metric of a route influences how the FortiGate dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to:</p> <ul style="list-style-type: none"> Hop count: Routes learned through RIP Relative cost: Routes learned through OSPF Multi-Exit Discriminator (MED): Routes learned through BGP. By default, the MED value associated with a BGP route is zero. However, the MED value can be modified

Field	Description
	dynamically. If the value was changed from the default, the Metric column displays a non-zero value.
Priority	In static routes, priorities are 0 by default. When two routes have an equal distance, the route with the lower priority number will take precedence.
VRF	Virtual routing and forwarding (VRF) allows multiple routing table instances to co-exist. VRF can be assigned to an Interface. Packets are only forwarded between interfaces with the same VRF.
Up Since	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable.

Viewing the routing table in the CLI

Viewing the routing table using the CLI displays the same routes as you would see in the GUI.

If VDOMs are enabled on the FortiGate, all routing-related CLI commands must be run within a VDOM and not in the global context.

To view the routing table using the CLI:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default
Routing table for VRF=0
S*    0.0.0.0/0 [1/0] via 172.31.0.1, MPLS [1/0] via 192.168.2.1, port1 [1/0] via
192.168.122.1, port2
S     1.2.3.4/32 [10/0] via 172.16.100.81, VLAN100
C     10.10.2.0/24 is directly connected, hub
C     10.10.2.1/32 is directly connected, hub
O     10.10.10.0/24 [110/101] via 192.168.2.1, port1, 01:54:18
C     10.253.240.0/20 is directly connected, wqt.root
S     110.2.2.122/32 [22/0] via 2.2.2.2, port2, [3/3]
C     172.16.50.0/24 is directly connected, WAN1-VLAN50
C     172.16.60.0/24 is directly connected, WAN2-VLAN60
C     172.16.100.0/24 is directly connected, VLAN100
C     172.31.0.0/30 is directly connected, MPLS
C     172.31.0.2/32 is directly connected, MPLS
B     192.168.0.0/24 [20/0] via 172.31.0.1, MPLS, 00:31:43
C     192.168.2.0/24 is directly connected, port1
C     192.168.20.0/24 is directly connected, port3
C     192.168.99.0/24 is directly connected, Port1-VLAN99
C     192.168.122.0/24 is directly connected, port2
Routing table for VRF=10
C     172.16.101.0/24 is directly connected, VLAN101
```

Examining an entry:

```
B      192.168.0.0/24 [20/0] via 172.31.0.1, MPLS, 00:31:43
```

Value	Description
B	BGP. The routing protocol used.
192.168.0.0/24	The destination of this route, including netmask.
[20/0]	20 indicates an administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF.
172.31.0.1	The gateway or next hop.
MPLS	The interface that the route uses.
00:31:43	The age of the route in HH:MM:SS.

Viewing the routing database

The routing database consists of all learned routes from all routing protocols before they are injected into the routing table. This likely lists more routes than the routing table as it consists of routes to the same destinations with different distances. Only the best routes are injected into the routing table. However, it is useful to see all learned routes for troubleshooting purposes.

To view the routing database using the CLI:

```
# get router info routing-table database
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
> - selected route, * - FIB route, p - stale info

Routing table for VRF=0
S   *> 0.0.0.0/0 [1/0] via 172.31.0.1, MPLS
    *>          [1/0] via 192.168.2.1, port1
    *>          [1/0] via 192.168.122.1, port2
S   *> 1.2.3.4/32 [10/0] via 172.16.100.81, VLAN100
C   *> 10.10.2.0/24 is directly connected, hub
C   *> 10.10.2.1/32 is directly connected, hub
O   *> 10.10.10.0/24 [110/101] via 192.168.2.1, port1, 02:10:17
C   *> 10.253.240.0/20 is directly connected, wqt.root
S   *> 110.2.2.122/32 [22/0] via 2.2.2.2, port2, [3/3]
C   *> 172.16.50.0/24 is directly connected, WAN1-VLAN50
C   *> 172.16.60.0/24 is directly connected, WAN2-VLAN60
C   *> 172.16.100.0/24 is directly connected, VLAN100
O   172.31.0.0/30 [110/201] via 192.168.2.1, port1, 00:47:36
C   *> 172.31.0.0/30 is directly connected, MPLS
```

Selected routes are marked by the > symbol. In the above example, the OSPF route to destination 172.31.0.0/30 is not selected.

Kernel routing table

The kernel routing table makes up the actual Forwarding Information Base (FIB) that used to make forwarding decisions for each packet. The routes here are often referred to as kernel routes. Parts of this table are derived from the routing table that is generated by the routing daemon.

To view the kernel routing table using the CLI:

```
# get router info kernel
tab=254 vf=0 scope=0 type=1 proto=11 prio=0 0.0.0.0/0.0.0.0/0->0.0.0.0/0 pref=0.0.0.0
    gwy=172.31.0.1 flag=04 hops=0 oif=31(MPLS)
    gwy=192.168.2.1 flag=04 hops=0 oif=3(port1)
    gwy=192.168.122.1 flag=04 hops=0 oif=4(port2)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.122.98/255.255.255.255/0->1.1.1.1/32
pref=0.0.0.0 gwy=192.168.122.1 dev=4(port2)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 172.31.0.2/255.255.255.255/0->1.1.1.1/32
pref=0.0.0.0 gwy=172.31.0.1 dev=31(MPLS)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.2.5/255.255.255.255/0->1.1.1.1/32
pref=0.0.0.0 gwy=192.168.2.1 dev=3(port1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=0 0.0.0.0/0.0.0.0/0->1.2.3.4/32 pref=0.0.0.0
gwy=172.16.100.81 dev=20(VLAN100)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.122.98/255.255.255.255/0->8.8.8.8/32
pref=0.0.0.0 gwy=192.168.122.1 dev=4(port2)
```

The kernel routing table entries are:

Value	Description
tab	Table number: It will either be 254 (unicast) or 255 (multicast).
vf	Virtual domain of the firewall: It is the VDOM index number. If VDOMs are not enabled, this number is 0.
type	Type of routing connection. Valid values include: <ul style="list-style-type: none"> • 0 - unspecific • 1 - unicast • 2 - local • 3 - broadcast • 4 - anycast • 5 - multicast • 6 - blackhole • 7 - unreachable • 8 - prohibited
proto	Type of installation that indicates where the route came from. Valid values include: <ul style="list-style-type: none"> • 0 - unspecific • 2 - kernel • 11 - ZebOS routing module • 14 - FortiOS • 15 - HA • 16 - authentication based

Value	Description
	<ul style="list-style-type: none"> 17 - HA1
prio	Priority of the route. Lower priorities are preferred.
->0.0.0.0/0 (->x.x.x.x/mask)	The IP address and subnet mask of the destination.
pref	Preferred next hop along this route.
gwy	Gateway: The address of the gateway this route will use.
dev	Outgoing interface index: This number is associated with the interface for this route. If VDOMs are enabled, the VDOM is also included here. If an interface alias is set for this interface, it is also displayed here.

Route cache

The route cache contains recently used routing entries in a table. It is consulted before the routing table to speed up the route look-up process.

To view the route cache using the CLI:

```
# diagnose ip rtcache list
family=02 tab=254 vrf=0 vf=0 type=01 tos=0 flag=00000200
0.0.0.0@0->208.91.113.230@3(port1) gwy=192.168.2.1 prefsrc=192.168.2.5
ci: ref=0 lastused=1 expire=0 err=00000000 used=5 br=0 pmtu=1500

family=02 tab=254 vrf=0 vf=0 type=01 tos=0 flag=00000200
192.168.2.5@0->8.8.8.8@3(port1) gwy=192.168.2.1 prefsrc=0.0.0.0
ci: ref=0 lastused=0 expire=0 err=00000000 used=2 br=0 pmtu=1500

family=02 tab=254 vrf=0 vf=0 type=02 tos=8 flag=80000200
8.8.8.8@31(MPLS)->172.31.0.2@6(root) gwy=0.0.0.0 prefsrc=172.31.0.2
ci: ref=1 lastused=0 expire=0 err=00000000 used=0 br=0 pmtu=16436

family=02 tab=254 vrf=0 vf=0 type=02 tos=0 flag=84000200
192.168.20.6@5(port3)->192.168.20.5@6(root) gwy=0.0.0.0 prefsrc=192.168.20.5
ci: ref=2 lastused=0 expire=0 err=00000000 used=1 br=0 pmtu=16436
...
```

The size of the route cache is calculated by the kernel, but can be modified.

To modify the size of the route cache:

```
config system global
    set max-route-cache-size <number_of_cache_entries>
end
```

Route look-up

Route look-up typically occurs twice in the life of a session. Once when the first packet is sent by the originator and once more when the first reply packet is sent from the responder. When a route look-up occurs, the routing information is written to the session table and the route cache. If routing changes occur during the life of a session, additional routing look-ups may occur.

FortiGate performs a route look-up in the following order:

1. Policy-based routes: If a match occurs and the action is to forward, traffic is forwarded based on the policy route.
2. Route Cache: If there are no matches, FortiGate looks for the route in the route cache.
3. Forwarding Information Base, otherwise known as the kernel routing table.
4. If no match occurs, the packet is dropped.

Searching the routing table

When there are many routes in your routing table, you can perform a quick search by using the search bar to specify your criteria, or apply filters on the column header to display only certain routes. For example, if you want to only display static routes, you may use "static" as the search term, or filter by the *Type* field with value *Static*.

Route look-up on the other hand provides a utility for you to enter criteria such as *Destination*, *Destination Port*, *Source*, *Protocol* and/or *Source Interface*, in order to determine the route that a packet will take. Once you click *Search*, the corresponding route will be highlighted.

You can also use the CLI for a route look-up. The CLI provides a basic route look-up tool.

To look-up a route in the CLI:

```
# get router info routing-table details 4.4.4.4
Routing table for VRF=0
Routing entry for 0.0.0.0/0
    Known via "static", distance 1, metric 0, best
    * 172.31.0.1, via MPLS distance 0
    * 192.168.2.1, via port1 distance 0
    * 192.168.122.1, via port2 distance 0
```

Blackhole routes

Sometimes upon routing table changes, it is not desirable for traffic to be routed to a different gateway. For example, you may have traffic destined for a remote office routed through your IPsec VPN interface. When the VPN is down, traffic will try to re-route to another interface. However, this may not be viable and traffic will instead be routed to your default route through your WAN, which is not desirable. Traffic may also be routed to another VPN, which you do not want. For such scenarios, it is good to define a blackhole route so that traffic is dropped when your desired route is down. Upon reconnection, your desired route is once again added to the routing table and your traffic will resume routing to your desired interface. For this reason, blackhole routes are created when you configure an IPsec VPN using the IPsec wizard.

To create a blackhole route in the GUI:

1. Go to *Network > Static Routes*.
2. Click *Create New*. The *New Static Route* screen appears.
3. Specify a *Destination* type.

4. Select *Blackhole* from the *Interface* field.
5. Type the desired *Administrative Distance*.
6. Click *OK*.

Route priority for a *Blackhole* route can only be configured from the CLI.

Reverse path look-up

Whenever a packet arrives at one of the interfaces on a FortiGate, the FortiGate determines whether the packet was received on a legitimate interface by doing a reverse look-up using the source IP address in the packet header. This protects against IP spoofing attacks. If the FortiGate does not have a route to the source IP address through the interface on which the packet was received, the FortiGate drops the packet as per Reverse Path Forwarding (RPF) check. There are two modes of RPF – feasible path and strict. The default feasible RPF mode checks only for the existence of at least one active route back to the source using the incoming interface. The strict RPF check ensures the best route back to the source is used as the incoming interface.

To configure a strict Reverse Path Forwarding check in the CLI:

```
config system settings
    set strict-src-check enable
end
```

You can remove RPF state checks without needing to enable asymmetric routing by disabling state checks for traffic received on specific interfaces. Disabling state checks makes a FortiGate less secure and should only be done with caution for troubleshooting purposes.

To remove Reverse Path Forwarding checks from the state evaluation process in the CLI:

```
config system interface
    edit <interface_name>
        set src-check disable
    next
end
```

Asymmetric routing

Asymmetric routing occurs when request and response packets follow different paths that do not cross the same firewall.

In the following topology, traffic between PC1 and PC2 takes two different paths.

Traffic from PC1 to PC2 goes through the FortiGate, while traffic from PC2 to PC1 does not.

In TCP, if the packets in the request and response directions follow different paths, the FortiGate will block the packets, since the TCP three-way handshake is not established through the FortiGate.

Scenario 1: PC1 starts a TCP connection with PC2

1. The TCP SYN is allowed by the FortiGate.
2. The TCP SYN/ACK bypasses the FortiGate.
3. The TCP ACK is blocked by the FortiGate.
4. Subsequent TCP packets are blocked by the FortiGate.

Scenario 2: PC2 starts a TCP connection with PC1

1. The TCP SYN bypasses the FortiGate.
2. The TCP SYN/ACK is blocked by the FortiGate.
3. Subsequent TCP packets are blocked by the FortiGate.

In ICMP, consider the following scenarios.

Scenario 1: PC1 pings PC2

1. The ICMP request passes through the FortiGate. A session is created.
2. The ICMP reply bypasses the FortiGate, but reaches PC1. The ping is successful.
3. The ICMP request passes through the FortiGate, and it matches the previous session.
4. The ICMP reply bypasses the FortiGate, but it reaches PC1. The ping is successful.
5. Subsequent ICMP requests are allowed by the FortiGate.

Scenario 2: PC2 pings PC1

1. The ICMP request bypasses the FortiGate, but it reaches PC1.
2. The ICMP reply passes through the FortiGate. No session is matched, and the packet is dropped.
3. Subsequent ICMP replies are blocked by the FortiGate.

If an ICMP request does not pass through the FortiGate, but the response passes through the FortiGate, then by default it blocks the packet as invalid.

Permitting asymmetric routing

If required, the FortiGate can be configured to permit asymmetric routing.

To permit asymmetric routing:

```
config system settings
    set asymroute enable
end
```

This setting should be used only when the asymmetric routing issue cannot be resolved by ensuring both directions of traffic pass through the FortiGate.

When asymmetric routing is enabled and occurs, the FortiGate cannot inspect all traffic. Potentially malicious traffic may pass through and compromise the security of the network.

Asymmetric routing behaves as follows when it is permitted by the FortiGate:

TCP packets

Scenario 1: PC1 starts a TCP connection with PC2

1. The TCP SYN is allowed by the FortiGate. The FortiGate creates a session, checks the firewall policies, and applies the configuration from the matching policy (UTM inspection, NAT, traffic shaping, and so on).
2. The TCP SYN/ACK bypasses the FortiGate.
3. The TCP ACK is allowed by the FortiGate. The packet matches the previously created session.
4. Subsequent TCP packets are allowed by the FortiGate. The packets in the session can also be offloaded where applicable.

Scenario 2: PC2 starts a TCP connection with PC1

1. The TCP SYN bypasses the FortiGate.
2. The TCP SYN/ACK is allowed by the FortiGate. No session is matched. The packet passes to the CPU and is forwarded based on the routing table.
3. The TCP ACK bypasses the FortiGate.
4. Subsequent TCP packets are allowed by the FortiGate. The FortiGate acts as a router that only makes routing decisions. No security inspection is performed.

ICMP packets

Scenario 1: PC1 pings PC2

1. There is no difference from when asymmetric routing is disabled.

Scenario 2: PC2 pings PC1

1. The ICMP request bypasses the FortiGate, but it reaches PC1.
2. The ICMP reply passes through the FortiGate. No session is matched. The packet passes to the CPU and is forwarded based on the routing table.
3. Subsequent ICMP replies are allowed by the FortiGate. The FortiGate acts as a router that only makes routing decisions. No security inspection is performed.

UDP packets

Asymmetric routing does not affect UDP packets. UDP packets are checked by the session table regardless of asymmetric routing. A policy is required to allow UDP.

Routing changes

When routing changes occur, routing look-up may occur on an existing session depending on certain configurations.

Routing changes without SNAT

When a routing change occurs, FortiGate flushes all routing information from the session table and performs new routing look-up for all new packets on arrival by default. You can modify the default behavior using the following commands:

```
config system interface
    edit <interface>
```

```

        set preserve-session-route enable
    next
end

```

By enabling `preserve-session-route`, the FortiGate marks existing session routing information as persistent. Therefore, routing look-up only occurs on new sessions.

Routing changes with SNAT

When SNAT is enabled, the default behavior is opposite to that of when SNAT is not enabled. After a routing change occurs, sessions with SNAT keep using the same outbound interface as long as the old route is still active. This may be the case if the priority of the static route was changed. You can modify this default behavior using the following commands:

```

config system global
    set snat-route-change enable
end

```

By enabling `snat-route-change`, sessions with SNAT will require new route look-up when a routing change occurs. This will apply a new SNAT to the session.

Static route tags

When a static route is configured with a route tag, it is matched in the route map, and then used to set the route's metric and advertise to the BGP neighbor. In the following example, route tag 565 is used, and router R1 receives the advertised route from the FortiGate router R5.

To configure the FortiGate:

1. Configure the static route:

```

config router static
    edit 1
        set dst 77.7.7.7 255.255.255.255
        set distance 2
        set device "R560"
        set tag 565
    next
end

```

2. Configure the route map:

```

config router route-map
    edit "map1"
        config rule
            edit 2
                set match-tag 565
                set set-metric 2301
            next
        end
    end
end

```

```

    next
end

```

3. Configure the BGP neighbor:

```

config router bgp
  config neighbor
    edit "10.100.1.2"
      set route-map-out "map1"
    next
  end
end

```

On its neighbor side, router R1 receives the advertised route from the FortiGate router R5.

4. Verify the BGP routing table:

```

# get router info routing-table bgp
Routing table for VRF=0
B      77.7.7.7/32 [20/2301] via 10.100.1.1 (recursive is directly connected, R150),
03:18:53, [1/0]

```

5. Verify the network community:

```

# get router info bgp network 77.7.7.7/32
VRF 0 BGP routing table entry for 77.7.7.7/32
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Advertised to non peer-group peers:
    2.2.2.2 3.3.3.3 10.100.1.5 2000::2:2:2:2
  Original VRF 0
  20
    10.100.1.1 from 10.100.1.1 (5.5.5.5)
      Origin incomplete metric 2301, localpref 200, valid, external, best
      Last update: Wed Oct  5 16:48:28 2022

```

Defining a preferred source IP for local-out egress interfaces

The preferred source IP can be configured on a static route so that local-out traffic is sourced from that IP. In the following example, a source IP is defined per static route. Local traffic that uses the static route will use the source IP instead of the interface IP associated with the route.

To configure preferred source IPs for static routes:

1. Configure the static routes:

```

config router static
  edit 22
    set dst 172.17.254.0 255.255.255.0
    set gateway 172.16.200.254

```

```

        set preferred-source 1.1.1.1
        set distance 2
        set device "port1"
    next
    edit 23
        set dst 172.17.254.0 255.255.255.0
        set gateway 172.16.203.2
        set preferred-source 1.1.1.2
        set distance 2
        set device "agg1"
    next
end

```

2. Configure the primary DNS server IP address:

```

config system dns
    set primary 172.17.254.148
end

```

To verify the configuration:

1. Verify the kernel routing table:

```

# get router info kernel
...
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.17.254.0/24
pref=0.0.0.0
    gwy=172.16.200.254 flag=14 hops=0 oif=9(port1) pref=1.1.1.1
    gwy=172.16.203.2 flag=14 hops=0 oif=33(agg1) pref=1.1.1.2

```

2. Verify the routing table for 172.17.254.148:

```

# get router info routing-table details 172.17.254.148
Routing table for VRF=0
Routing entry for 172.17.254.0/24
    Known via "static", distance 2, metric 0, best
    * vrf 0 172.16.200.254, via port1, prefsrc 1.1.1.1
    * vrf 0 172.16.203.2, via agg1, prefsrc 1.1.1.2

```

3. Run a sniffer trace after some traffic passes:

```

# diagnose sniffer packet any "host 172.17.254.148" 4
interfaces=[any]
filters=[host 172.17.254.148]
1.319811 port1 out 1.1.1.1.1371 -> 172.17.254.148.53: udp 43
1.320095 port1 in 172.17.254.148.53 -> 1.1.1.1.1371: udp 310
1.921718 port1 out 1.1.1.1.1371 -> 172.17.254.148.53: udp 27
2.031520 port1 in 172.17.254.148.53 -> 1.1.1.1.1371: udp 213

```

When DNS traffic leaves the FortiGate and is routed through port1, the source address 1.1.1.1 is used.

Policy routes

Policy routing allows you to specify an interface to route traffic. This is useful when you need to route certain types of network traffic differently than you would if you were using the routing table. You can use the incoming traffic's protocol, source or destination address, source interface, or port number to determine where to send the traffic.

When a packet arrives, the FortiGate starts at the top of the policy route list and attempts to match the packet with a policy. For a match to be found, the policy must contain enough information to route the packet. At a minimum, this requires the outgoing interface to forward the traffic, and the gateway to route the traffic to. If one or both of these are not specified in the policy route, then the FortiGate searches the routing table to find the best active route that corresponds to the policy route. If no routes are found in the routing table, then the policy route does not match the packet. The FortiGate continues down the policy route list until it reaches the end. If no matches are found, then the FortiGate does a route lookup using the routing table.

Policy routes are sometimes referred to as Policy-based routes (PBR).

Configuring a policy route

In this example, a policy route is configured to send all FTP traffic received at port1 out through port4 and to a next hop router at 172.20.120.23. To route FTP traffic, the protocol is set to TCP (6) and the destination ports are set to 21 (the FTP port).

To configure a policy route in the GUI:

1. Go to *Network > Policy Routes*.
2. Click *Create New > Policy Route*.
3. Configure the following fields:

Incoming interface	port1
Source Address	0.0.0.0/0.0.0.0
Destination Address	0.0.0.0/0.0.0.0
Protocol	TCP
Destination ports	21 - 21
Type of service	0x00
Bit Mask	0x00
Outgoing interface	Enable and select port4
Gateway address	172.20.120.23

New Routing Policy

If incoming traffic matches:

Incoming Interface: port1

Source Address: IP/Netmask 0.0.0.0/0.0.0.0

Destination Address: IP/Netmask 0.0.0.0/0.0.0.0

Protocol: TCP

Source ports: 0 - 65535

Destination ports: 21 - 21

Type of service: 0x00

Then:

Action: Forward Traffic

Outgoing interface: port4

Gateway address: 172.20.120.23

Status: Enabled

OK Cancel

4. Click **OK**.

To configure a policy route in the CLI:

```
config router policy
  edit 1
    set input-device "port1"
    set src "0.0.0.0/0.0.0.0"
    set dst "0.0.0.0/0.0.0.0"
    set protocol 6
    set start-port 21
    set end-port 21
    set gateway 172.20.120.23
    set output-device "port4"
    set tos 0x00
    set tos-mask 0x00
  next
end
```

Moving a policy route

A routing policy is added to the bottom of the table when it is created. Routing policies can be moved to a different location in the table to change the order of preference. In this example, routing policy 3 will be moved before routing policy 2.

To move a policy route in the GUI:

1. Go to *Network > Policy Routes*.
2. In the table, select the policy route.

<div>+ Create New</div>		<div>Edit</div>	<div>Delete</div>	<div>Search</div>		<div>Q</div>
Seq.#	Incoming Interface	Outgoing Interface	Source	Destination	Hit Count	
IPv4						
1	<div>VPN_A_Tunnel (Branch-HQ-A)</div>	<div>VPN_A_Tunnel (Branch-HQ-A)</div>			0	
2	<div>VPN_B_Tunnel (Branch-HQ-B)</div>	<div>VPN_B_Tunnel (Branch-HQ-B)</div>			0	
3	<div>HQ-MPLS (HQ-MPLS)</div>	<div>HQ-MPLS (HQ-MPLS)</div>			0	
						<div>Updated: 13:27:34</div>

3. Drag the selected policy route to the desired position.

<div><div>+ Create New</div><div>Edit</div><div>Delete</div></div>		<div>Search</div>		<div>Q</div>	
Seq.#	Incoming Interface	Outgoing Interface	Source	Destination	Hit Count
<div><div>IPv4</div></div>					
1	<div><div></div>VPN_A_Tunnel (Branch-HQ-A)</div>	<div><div></div>VPN_A_Tunnel (Branch-HQ-A)</div>			0
3	<div><div></div>HQ-MPLS (HQ-MPLS)</div>	<div><div></div>HQ-MPLS (HQ-MPLS)</div>			0
2	<div><div></div>VPN_B_Tunnel (Branch-HQ-B)</div>	<div><div></div>VPN_B_Tunnel (Branch-HQ-B)</div>			0
<div><div>Updated: 13:26:38</div></div>					

To move a policy route in the CLI:

```
config router policy
  move 3 after 1
end
```

Equal cost multi-path

Equal cost multi-path (ECMP) is a mechanism that allows a FortiGate to load-balance routed traffic over multiple gateways. Just like routes in a routing table, ECMP is considered after policy routing, so any matching policy routes will take precedence over ECMP.

ECMP pre-requisites are as follows:

- Routes must have the same destination and costs. In the case of static routes, costs include distance and priority
- Routes are sourced from the same routing protocol. Supported protocols include static routing, OSPF, and BGP

ECMP and SD-WAN implicit rule

ECMP and SD-WAN implicit rule are essentially similar in the sense that an SD-WAN implicit rule is processed after SD-WAN service rules are processed. See [Implicit rule on page 775](#) to learn more.

The following table summarizes the different load-balancing algorithms supported by each:

ECMP	SD-WAN		Description
	GUI	CLI	
source-ip-based	Source IP	source-ip-based	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address use the same path. This is the default selection.

ECMP	SD-WAN		Description
	GUI	CLI	
weight-based	Sessions	weight-based	The workload is distributed based on the number of sessions that are connected through the interface. The weight that you assign to each interface is used to calculate the percentage of the total sessions allowed to connect through an interface, and the sessions are distributed to the interfaces accordingly.
usage-based	Spillover	usage-based	The interface is used until the traffic bandwidth exceeds the ingress and egress thresholds that you set for that interface. Additional traffic is then sent through the next interface member.
source-dest-ip-based	Source-Destination IP	source-dest-ip-based	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address and go to the same destination IP address use the same path.
Not supported	Volume	measured-volume-based	This mode is supported in SD-WAN only. The workload is distributed based on the number of packets that are going through the interface.

To configure the ECMP algorithm from the CLI:

- At the VDOM level:

```
config system settings
    set v4-ecmp-mode {source-ip-based* | weight-based | usage-based | source-dest-ip-based}
end
```

- If SD-WAN is enabled, the above option is not available and ECMP is configured under the SD-WAN settings:

```
config system sdwan
    set status enable
    set load-balance-mode {source-ip-based* | weight-based | usage-based | source-dest-ip-based | measured-volume-based}
end
```

For ECMP in IPv6, the mode must also be configured under SD-WAN:

```
# diagnose sys vd list
system fib version=63
list virtual firewall info:
name=root/root index=0 enabled fib_ver=40 use=168 rt_num=46 asym_rt=0 sip_helper=0, sip_nat_trace=1, mc_fwd=0, mc_ttl_nc=0, tpmc_sk_pl=0
ecmp=source-ip-based, ecmp6=source-ip-based asym_rt6=0 rt6_num=55 strict_src_check=0 dns_log=1 ses_num=20 ses6_num=0 pkt_num=19154477
```

To change the number of paths allowed by ECMP:

```
config system settings
    set ecmp-max-paths <number of paths>
end
```

Setting `ecmp-max-paths` to the lowest value of 1 is equivalent to disabling ECMP.

ECMP configuration examples

The following examples demonstrate the behavior of ECMP in different scenarios:

- [Example 1: Default ECMP on page 423](#)
- [Example 2: Same distance, different priority on page 424](#)
- [Example 3: Weight-based ECMP on page 424](#)
- [Example 4: Load-balancing BGP routes on page 425](#)

Example 1: Default ECMP

```
config router static
    edit 1
        set gateway 172.16.151.1
        set device "port1"
    next
    edit 2
        set gateway 192.168.2.1
        set device "port2"
    next
end

# get router info routing-table all
Routing table for VRF=0
S*    0.0.0.0/0 [10/0] via 172.16.151.1, port1
      [10/0] via 192.168.2.1, port2
C     172.16.151.0/24 is directly connected, port1
C     192.168.2.0/24 is directly connected, port2
```

Result:

Both routes are added to the routing table and load-balanced based on the source IP.

Example 2: Same distance, different priority

```
config router static
  edit 1
    set gateway 172.16.151.1
    set priority 5
    set device "port1"
  next
  edit 2
    set gateway 192.168.2.1
    set device "port2"
  next
end

# get router info routing-table all
Routing table for VRF=0
S*    0.0.0.0/0 [10/0] via 192.168.2.1, port2
      [10/0] via 172.16.151.1, port1, [5/0]
C     172.16.151.0/24 is directly connected, port1
C     192.168.2.0/24 is directly connected, port2
```

Result:

Both routes are added to the routing table, but traffic is routed to `port2` which has a lower priority value with a default of 0.

Example 3: Weight-based ECMP

```
config router static
  edit 3
    set dst 10.10.30.0 255.255.255.0
    set weight 80
    set device "vpn2HQ1"
  next
  edit 5
    set dst 10.10.30.0 255.255.255.0
    set weight 20
    set device "vpn2HQ2"
  next
end

# get router info routing-table all
Routing table for VRF=0
...
S     10.10.30.0/24 [10/0] is directly connected, vpn2HQ1, [0/80]
      [10/0] is directly connected, vpn2HQ2, [0/20]
C     172.16.151.0/24 is directly connected, port1
C     192.168.0.0/24 is directly connected, port3
C     192.168.2.0/24 is directly connected, port2
```

Result:

Both routes are added to the routing table, but 80% of the sessions to `10.10.30.0/24` are routed to `vpn2HQ1`, and 20% are routed to `vpn2HQ2`.

Example 4: Load-balancing BGP routes

```

config router bgp
  set as 64511
  set router-id 192.168.2.86
  set ebgp-multipath enable
  config neighbor
    edit "192.168.2.84"
      set remote-as 64512
    next
    edit "192.168.2.87"
      set remote-as 64512
    next
  end
end
# get router info routing-table all
Routing table for VRF=0
...
C   172.16.151.0/24 is directly connected, port1
C   192.168.0.0/24 is directly connected, port3
C   192.168.2.0/24 is directly connected, port2
B   192.168.80.0/24 [20/0] via 192.168.2.84, port2, 00:00:33
    [20/0] via 192.168.2.87, port2, 00:00:33

```

Result:

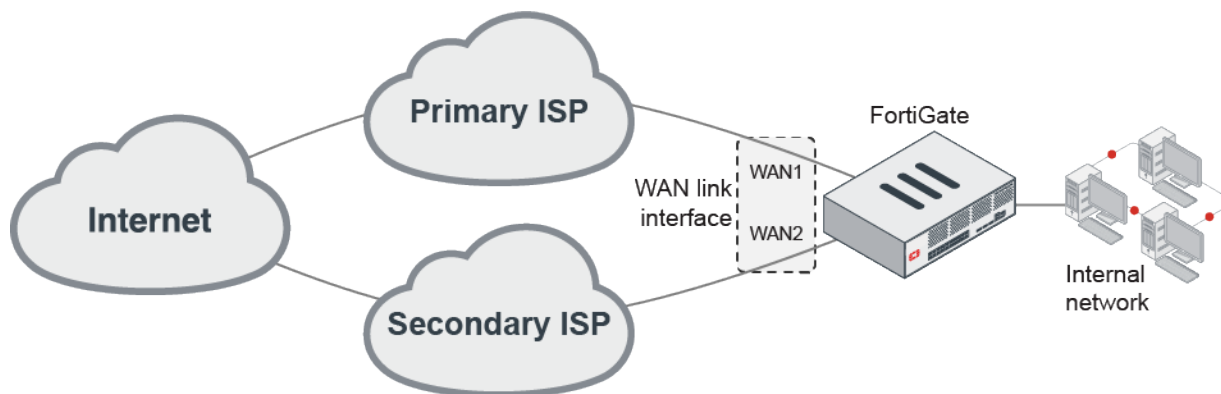

The network 192.168.80.0/24 is advertised by two BGP neighbors. Both routes are added to the routing table, and traffic is load-balanced based on Source IP.

For multiple BGP paths to be added to the routing table, you must enable `ebgp-multipath` for eBGP or `ibgp-multipath` for iBGP. These settings are disabled by default.

Dual internet connections

Dual internet connections, also referred to as dual WAN or redundant internet connections, refers to using two FortiGate interfaces to connect to the Internet. This is generally accomplished with SD-WAN, but this legacy solution provides the means to configure dual WAN without using SD-WAN. You can use dual internet connections in several ways:

- Link redundancy: If one interface goes down, the second interface automatically becomes the main connection.
- Load sharing: This ensures better throughput.
- Use a combination of link redundancy and load sharing.

This section describes the following dual internet connection scenarios:

- [Scenario 1: Link redundancy and no load-sharing on page 426](#)
- [Scenario 2: Load-sharing and no link redundancy on page 428](#)
- [Scenario 3: Link redundancy and load-sharing on page 429](#)

Scenario 1: Link redundancy and no load-sharing

Link redundancy ensures that if your Internet access is no longer available through a certain port, the FortiGate uses an alternate port to connect to the Internet.

In this scenario, two interfaces, WAN1 and WAN2, are connected to the Internet using two different ISPs. WAN1 is the primary connection. In the event of a failure of WAN1, WAN2 automatically becomes the connection to the Internet. For this configuration to function correctly, you must configure the following settings:

- [Link health monitor on page 426](#): To determine when the primary interface (WAN1) is down and when the connection returns.
- [Routing on page 427](#): Configure a default route for each interface.
- [Security policies on page 428](#): Configure security policies to allow traffic through each interface to the internal network.

Link health monitor

Adding a link health monitor is required for routing failover traffic. A link health monitor confirms the device interface connectivity by probing a gateway or server at regular intervals to ensure it is online and working. When the server is not accessible, that interface is marked as down.

Set the `interval` (how often to send a ping) and `failtime` (how many lost pings are considered a failure). A smaller interval value and smaller number of lost pings results in faster detection, but creates more traffic on your network.

The link health monitor supports both IPv4 and IPv6, and various other protocols including ping, tcp-echo, udp-echo, http, and twamp.

To add a link health monitor (IPv4) using the CLI:

```
config system link-monitor
  edit <link-monitor-name>
    set addr-mode ipv4
    set srcintf <interface-name>
    set server <server-IP-address>
    set protocol {ping tcp-echo udp-echo http twamp}
    set gateway-ip <gateway-IP-address>
    set interval <seconds>
    set failtime <retry-attempts>
    set recoverytime <number-of-successful-responses>
    set status enable
  next
end
```

Option	Description
<code>set update-cascade-interface {enable disable}</code>	This option is used in conjunction with fail-detect and fail-alert options in interface settings to cascade the link failure down to another interface. See the Bring other interfaces down when link monitor fails KB article for details.
<code>set update-static-route {enable disable}</code>	When the link fails, all static routes associated with the interface will be removed.

Routing

You must configure a default route for each interface and indicate your preferred route as follows:

- Specify different distances for the two routes. The lower of the two distance values is declared active and placed in the routing table.

Or

- Specify the same distance for the two routes, but give a higher priority to the route you prefer by defining a lower value. Both routes will be added to the routing table, but the route with a higher priority will be chosen as the best route

In the following example, we will use the first method to configure different distances for the two routes. You might not be able to connect to the backup WAN interface because the FortiGate does not route traffic out of the backup interface. The FortiGate performs a reverse path look-up to prevent spoofed traffic. If an entry cannot be found in the routing table that sends the return traffic out through the same interface, the incoming traffic is dropped.

To configure the routing of the two interfaces using the GUI:

- Go to *Network > Static Routes*, and click *Create New*.
- Enter the following information:

Destination	For an IPv4 route, enter a subnet of 0.0.0.0/0.0.0.0. For an IPv6 route, enter a subnet of ::/0.
Interface	Select the primary connection. For example, wan1.
Gateway Address	Enter the gateway address.
Administrative Distance	Leave as the default of 10.

- Click *OK*.
- Repeat the above steps to set *Interface* to wan2 and *Administrative Distance* to 20.

To configure the routing of the two interfaces using the CLI:

```
config router {static | static6}
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set device wan1
    set gateway <gateway_address>
    set distance 10
```

```
next
edit 2
    set dst 0.0.0.0 0.0.0.0
    set device wan2
    set gateway <gateway_address>
    set distance 20
next
end
```

Security policies

When you create security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic is allowed to pass through WAN2, as it did with WAN1. This ensures that failover occurs with minimal effect to users.

Scenario 2: Load-sharing and no link redundancy

Load sharing may be accomplished in a few of the following ways of the many possible ways:

- By defining a preferred route with a lower distance, and specifying policy routes to route certain traffic to the secondary interface.
- By defining routes with same distance values but different priorities, and specifying policy routes to route certain traffic to the secondary interface.
- By defining routes with same distance values and priorities, and use equal-cost multi-path (ECMP) routing to equally distribute traffic between the WAN interfaces.

In our example, we will use the first option for our configuration. In this scenario, because link redundancy is not required, you do not have to configure a link monitor.

Traffic behaviour without a link monitor is as follows:

- If the remote gateway is down but the primary WAN interface of a FortiGate is still up, the FortiGate will continue to route traffic to the primary WAN. This results in traffic interruptions.
 - If the primary WAN interface of a FortiGate is down due to physical link issues, the FortiGate will remove routes to it and the secondary WAN routes will become active. Traffic will failover to the secondary WAN.
-

Routing

Configure routing as you did in [Scenario 1: Link redundancy and no load-sharing on page 426](#) above.

Policy routes

By configuring policy routes, you can redirect specific traffic to the secondary WAN interface. This works in this case because policy routes are checked before static routes. Therefore, even though the static route for the secondary WAN is not in the routing table, traffic can still be routed using the policy route.

In this example, we will create a policy route to route traffic from one address group to the secondary WAN interface.

To configure a policy route from the GUI:

1. Go to *Network > Policy Routes*, and click *Create New*.
2. Enter the following information:

Incoming interface	Define the source of the traffic. For example, <code>internal</code> .
Source Address	If we prefer to route traffic only from a group of addresses, define an address or address group, and add here.
Destination Address	Because we want to route all traffic from the address group here, we do not specify a destination address.
Protocol	Specify any protocol.
Action	Forward traffic.
Outgoing interface	Select the secondary WAN as the outbound interface. For example, <code>wan2</code> .
Gateway address	Input the gateway address for your secondary WAN. Because its default route has a higher distance value and is not added to the routing table, the gateway address must be added here.

3. Click OK.

To configure a policy route from the CLI:

```
config router policy
  edit 1
    set input-device "internal"
    set srcaddr "Laptops"
    set gateway <gateway_address>
    set output-device "wan2"
  next
end
```

Security policies

Your security policies should allow all traffic from `internal` to WAN1. Because link redundancy is not needed, you do not need to duplicate all WAN1 policies to WAN2. You will only need to define policies used in your policy route.

Scenario 3: Link redundancy and load-sharing

In this scenario, both the links are available to distribute Internet traffic with the primary WAN being preferred more. Should one of the interfaces fail, the FortiGate will continue to send traffic over the other active interface. The configuration is a combination of both the link redundancy and the load-sharing scenarios. The main difference is that the configured routes have equal distance values, with the route with a higher priority being preferred more. This ensures both routes are active in the routing table, but the route with a higher priority will be the best route.

Link health monitor

Link monitor must be configured for both the primary and the secondary WAN interfaces. This ensures that if the primary or the secondary WAN fails, the corresponding route is removed from the routing table and traffic re-routed to the other

WAN interface.

For configuration details, see sample configurations in [Scenario 1: Link redundancy and no load-sharing on page 426](#).

Routing

Both WAN interfaces must have default routes with the same distance. However, preference is given to the primary WAN by giving it a higher priority.

To configure the routing of the two interfaces using the CLI:

```
config router {static | static6}
    edit 1
        set dst 0.0.0.0 0.0.0.0
        set device wan1
        set gateway <gateway_address>
        set distance 10
        set priority 1
    next
    edit 2
        set dst 0.0.0.0 0.0.0.0
        set device wan2
        set gateway <gateway_address>
        set distance 10
        set priority 10
    next
end
```

Policy routes

The policy routes configuration is very similar to that of the policy routes in [Scenario 2: Load-sharing and no link redundancy on page 428](#), except that the gateway address should not be specified. When a policy route is matched and the gateway address is not specified, the FortiGate looks at the routing table to obtain the gateway. In case the secondary WAN fails, traffic may hit the policy route. Because there is no gateway specified and the route to the secondary WAN is removed by the link monitor, the policy route will be bypassed and traffic will continue through the primary WAN. This ensures that the policy route is not active when the link is down.

Security policies

When you create security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic is allowed to pass through WAN2, as it was with WAN1. This ensures that failover occurs with minimal effect to users.

Dynamic routing

Dynamic routing protocols attempt to build a map of the network topology to identify the best routes to reach different destinations. Instead of manually defining static routes, which is not scalable, dynamic routing typically involves defining neighbors and peer routers that share their network topology and routing updates with each other. Protocols like distance vector, link state, and path vector are used by popular routing protocols. FortiGate supports RIP, OSPF, BGP,

and IS-IS, which are interoperable with other vendors. When different dynamic routing protocols are used, the administrative distance of each protocol helps the FortiGate decide which route to pick.

Go to *System > Feature Visibility* and enable *Advanced Routing* to configure dynamic routing options in the GUI. See [Feature visibility on page 2702](#) for more information.

This section includes:

- [RIP on page 432](#)
- [OSPF on page 451](#)
- [BGP on page 468](#)
- [BFD on page 516](#)
- [Routing objects on page 526](#)

To view the routing table and perform route look-ups in the GUI, go to *Dashboard > Network* and expand the *Routing* widget.

To view the routing table in the CLI:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

S   192.168.20.0/24 [10/0] via 172.31.0.2, toKVM-MPLS
    [10/0] via 10.10.10.11, internal
```

RIP

Routing Information Protocol (RIP) is a distance-vector routing protocol that is intended for small and relatively homogeneous networks. It works well when there are minimal redundant paths and limited hop counts. FortiGate supports RIP version 1 ([RFC 1058](#)), RIP version 2 ([RFC 2453](#)), and RIPvng ([RFC 2080](#)).

Basic configuration

To configure the FortiGate to participate in RIP using the most basic configurations in the GUI:

1. Go to *Network > RIP*.
2. Set the *Version*.
3. Add the networks that the FortiGate will advertise in and that will participate in RIP.
4. If the interface settings, such as passive interface, authentication, or enabling send/receive updates, must be edited, add the interfaces to the *Interface* table.
5. Click *Apply*.

To configure the FortiGate to participate in RIP using the most basic configurations in the CLI:

```
config router rip
  config network
    edit 1
      set prefix <subnet> <netmask>
    next
  end
  config interface
    edit <interface>
      set receive-version 2
      set send-version 2
    next
  end
end
```

Default route injection

Enabling *Inject default route* (default-information-originate) advertises a default route into the FortiGate's RIP network.

To enable/disable default route injection in the GUI:

1. Go to *Network > RIP*.
2. Expand the *Advanced Options*.
3. Enable/disable *Inject Default Route*.
4. Click *OK*.

To enable/disable default route injection in the CLI:

```
config router rip
  set default-information-originate {enable | disable}
```

```
end
```

Default metric

The default metric setting sets the default metric for all redistributed routes. If the default metric is set to five, and static routes are redistributed, then static routes have a metric of five. This value can be overridden by setting a specific metric value for a protocol. For example, the static route metric can be set to two, overriding the default metric.

```
config router rip
    set default-metric 5
    config redistribute "static"
        set status enable
        set metric 2
    end
end
```

The default metric is five, but redistributed static routes have a metric of two. So, the default metric is overridden and the metric for redistributed static routes is two.

Timers

RIP uses the update, timeout, and garbage timers to regulate its performance. The default timer settings are effective in most configurations. When customizing the settings, you must ensure that the new settings are compatible with your local routers and access servers.

Go to *Network > RIP* and expand the *Advanced Options* to configure the timers in the GUI, or use the CLI:

```
config router rip
    set timeout-timer <seconds>
    set update-timer <seconds>
    set garbage-timer <seconds>
end
```

Update timer

The update timer sets the interval between routing updates. The default value is 30 seconds. Randomness is added to help prevent network congestion due to multiple routers trying to update their neighbors simultaneously. The update timer must be at least three times shorter than the timeout timer.

If there is significant RIP traffic on the network, you can increase the update timer to send fewer updates. You must apply the same increase to all routers on the network to avoid timeouts that degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time that a reachable route is kept in the routing table since its last update. The default value is 180 seconds. If an update for the route is received before the timeout period elapses, then the timer is reset. The timeout timer should be at least three times longer than the update timer.

If routers are not responding to updates in time, increasing the timeout timer can help. A longer timeout timer results in longer update periods, and the FortiGate could wait a considerable amount of time for all of the timers to expire on an unresponsive route.

Garbage timer

The garbage timer is the amount of time that the FortiGate advertises a route as unreachable before deleting the route from the routing table. The default value is 120 seconds.

If the timer is short, older routes are removed from the routing table more quickly, resulting in a smaller routing table. This can be useful for large networks, or if the network changes frequently.

Authentication and key chain

RIP version 1 (RIPv1) has no authentication. RIP version 2 (RIPv2) uses text passwords or authentication keys to ensure that the routing information exchanged between routers is reliable. For authentication to work, both the sending and receiving routers must be set to use authentication and must be configured with the same password or keys. An authentication key that uses authentication key chains is more secure than a text password because the intervals when the key is valid can be configured.

A key chain is a list of one or more authentication keys that each have send and receive lifetimes. Keys are used to authenticate routing packets only during the keys specified lifetimes. The FortiGate migrates from one key to the next according to the scheduled lifetimes. The sending and receiving routers should have synchronized system dates and times to ensure that both ends are using the same keys at the same times. You can overlap the key lifetimes to make sure that a key is always available, even if there is some difference in the system times.

To configure a text password in the GUI:

1. Go to *Network > RIP*.
2. In the *Interfaces* table, click *Create New*, or edit an existing interface.
3. Enable *Authentication* and select *Text* or *MD5*.
4. Click *Change*, and enter the password.
5. Configure the remaining settings as needed.
6. Click *OK*.
7. Click *Apply*.

To configure a text password in the CLI:

```
config router rip
  config interface
    edit <interface>
      set auth-mode {text | md5}
      set auth-string *****
    next
  end
end
```

To configure a key chain with two sequentially valid keys and use it in a RIP interface:

```
config router key-chain
  edit rip_key
    config key
      edit 1
        set accept-lifetime 09:00:00 23 02 2020 09:00:00 17 03 2020
        set send-lifetime 09:00:00 23 02 2020 09:00:00 17 03 2020
      next
    next
  end
end
```

```
        set key-string *****
    next
    edit 2
        set accept-lifetime 09:01:00 17 03 2020 09:00:00 1 04 2020
        set send-lifetime 09:01:00 17 03 2020 09:00:00 1 04 2020
        set key-string *****
    next
end
next
end

config router rip
    config interface
        edit port1
            set auth-keychain "rip_key"
        next
    end
end
```

Passive RIP interfaces

By default, an active RIP interface keeps the FortiGate routing table current by periodically asking neighbors for routes and sending out route updates. This can generate a significant amount of extra traffic in a large network.

A passive RIP interface listens to updates from other routers, but does not send out route updates. This can reduce network traffic when there are redundant routers in the network that would always send out essentially the same updates.

This example shows how to configure a passive RIPv2 interface on port1 using MD5 authentication.

To configure a passive RIP interface in the GUI:

1. Go to *Network > RIP*.
2. In the *Interfaces* table, click *Create New*.
3. Set *Interface* to the required interface.
4. Enable *Passive*.
5. Enable *Authentication* and set it to *MD5*.
6. Click *Change* and enter a password.
7. Set *Receive Version* to 2.
8. Click *OK*.

To configure a passive RIP interface in the CLI:

```
config router rip
    set passive-interface "port1"
    config interface
        edit "port1"
            set auth-mode md5
            set auth-string *****
            set receive-version 2
            set send-version 2
        next
    end
end
```

```

end
end

```

RIP and IPv6

RIP next generation (RIPng) is an extension of RIPv2 that includes support for IPv6. See [Basic RIPng example on page 449](#) and [IPv6 tunneling on page 641](#) for more information.

Basic RIP example

In this example, a medium-sized network is configured using RIPv2.

- Two core routers, RIP Router2 and RIP Router3, connect to the ISP router for two redundant paths to the internet.
- Two other routers, RIP Router1 and RIP Router4, connect to the two core routers and to different local networks.
- The ISP router is using RIP for its connections to the core routers, and redistributes its default route to the network - that is, default route injection is enabled.
- The ISP router uses NAT and has a static route to the internet. None of the other routers use NAT or static routes.

All of the FortiGate routers are configured as shown, using netmask 255.255.255.0. Firewall policies have been configured to allow the required traffic to flow across the interfaces.

Router	Interface	Interface name	IP address
Router1	port1	LoSales	10.11.101.101
	port2	vd12link0	10.11.201.101
	port3	vd13link0	10.11.202.101
Router2	port1	vd23link0	10.12.101.102
	port2	vd12link1	10.11.201.102
	port3	vd42link1	10.14.201.102
	port4	vdr2link1	172.20.120.102
Router3	port1	vd23link1	10.12.101.103
	port2	vd13link1	10.11.202.103
	port3	vd43link1	10.14.202.103
	port4	vdr3link1	172.20.121.103
Router4	port1	LoAccounting	10.14.101.104
	port2	vd42link0	10.14.201.104
	port3	vd43link0	10.14.202.104
ISP Router	port1	port1	To internet
	port2	vdr2link0	172.20.120.5
	port3	vdr3link0	172.20.121.5

After configuring each router, you can check the status of the connections by viewing the RIP database, RIP interfaces, and routing table. See [Verifying the configuration on page 442](#).

After the network is configured, you can test it to ensure that when network events occur, such as a downed link, routing updates are triggered and converge as expected. See [Testing the configuration and routing changes on page 446](#).

ISP router

To configure the ISP Router in the GUI:

1. Go to *Network > RIP*.
2. Set the *Version* to 2.
3. Under *Networks*, add two networks:
 - 172.20.120.0/255.255.255.0
 - 172.20.121.0/255.255.255.0
4. Add the interfaces:
 - a. In the *Interfaces* table, click *Create New*.
 - b. Set *Interface* to *port2*.
 - c. Leave the remaining settings as their default values.

- d. Click *OK*.
- e. Repeat these steps for *port3*.
5. Under *Advanced Options*, enable *Inject Default Route*.
This setting allows the ISP router to share its default 0.0.0.0 routes with other routers in the RIP network.
6. Click *Apply*.

To configure the ISP Router in the CLI:

```
config router rip
  set default-information-originate enable
  config network
    edit 1
      set prefix 172.20.121.0 255.255.255.0
    next
    edit 2
      set prefix 172.20.120.0 255.255.255.0
    next
  end
  config interface
    edit "port2"
      set receive-version 2
      set send-version 2
    next
    edit "port3"
      set receive-version 2
      set send-version 2
    next
  end
end
```

Router2 and Router3

Router2 and Router3 RIP configurations have different IP addresses, but are otherwise the same.

To configure Router2 and Router3 in the GUI:

1. Go to *Network > RIP*.
2. Set the *Version* to 2.
3. Under *Networks*, add the IP addresses for each port:

Router2	10.12.101.0/255.255.255.0
	10.11.201.0/255.255.255.0
	10.14.201.0/255.255.255.0
	172.20.120.0/255.255.255.0

Router3	10.12.101.0/255.255.255.0
	10.11.202.0/255.255.255.0
	10.14.202.0/255.255.255.0
	172.20.121.0/255.255.255.0

4. Add the interfaces:
 - a. In the *Interfaces* table, click *Create New*.
 - b. Set *Interface* to *port1*.
 - c. Leave the remaining settings as their default values.
 - d. Click *OK*.
 - e. Repeat these steps for *port2*, *port3*, and *port4*.
5. Click *Apply*.

To configure Router2 in the CLI:

```

config router rip
  config network
    edit 1
      set prefix 10.12.101.0 255.255.255.0
    next
    edit 2
      set prefix 10.11.201.0 255.255.255.0
    next
    edit 3
      set prefix 10.14.201.0 255.255.255.0
    next
    edit 4
      set prefix 172.20.120.0 255.255.255.0
    next
  end
config interface
  edit "port1"
    set receive-version 2
    set send-version 2
  next
  edit "port2"
    set receive-version 2
    set send-version 2
  next
  edit "port3"
    set receive-version 2
    set send-version 2
  next
  edit "port4"
    set receive-version 2
    set send-version 2
  next
end
end

```

To configure Router3 in the CLI:

```
config router rip
  config network
    edit 1
      set prefix 10.12.101.0 255.255.255.0
    next
    edit 2
      set prefix 10.11.202.0 255.255.255.0
    next
    edit 3
      set prefix 10.14.202.0 255.255.255.0
    next
    edit 4
      set prefix 172.20.121.0 255.255.255.0
    next
  end
config interface
  edit "port1"
    set receive-version 2
    set send-version 2
  next
  edit "port2"
    set receive-version 2
    set send-version 2
  next
  edit "port3"
    set receive-version 2
    set send-version 2
  next
  edit "port4"
    set receive-version 2
    set send-version 2
  next
end
end
```

Router1 and Router4

Router1 and Router4 RIP configurations have different IP addresses, but are otherwise the same.

To configure Router1 and Router4 in the GUI:

1. Go to *Network > RIP*.
2. Set the *Version* to 2.
3. Under *Networks*, add the IP addresses for each port:

Router1	10.11.101.0/255.255.255.0
	10.11.201.0/255.255.255.0
	10.11.202.0/255.255.255.0

Router4	10.14.101.0/255.255.255.0
	10.14.201.0/255.255.255.0
	10.14.202.0/255.255.255.0

4. Add the interfaces:

- a. In the *Interfaces* table, click *Create New*.
- b. Set *Interface* to *port1*.
- c. For port1 only, enable *Passive*.
- d. Leave the remaining settings as their default values.
- e. Click *OK*.
- f. Repeat these steps for *port2* and *port3*, making sure that *Passive* is disabled.

5. Click *Apply*.

To configure Router1 in the CLI:

```
config router rip
  config network
    edit 1
      set prefix 10.11.101.0 255.255.255.0
    next
    edit 2
      set prefix 10.11.201.0 255.255.255.0
    next
    edit 3
      set prefix 10.11.202.0 255.255.255.0
    next
  end
  set passive-interface "port1"
  config interface
    edit "port1"
      set receive-version 2
      set send-version 2
    next
    edit "port2"
      set receive-version 2
      set send-version 2
    next
    edit "port3"
      set receive-version 2
      set send-version 2
    next
  end
end
```

To configure Router4 in the CLI:

```
config router rip
  config network
    edit 1
      set prefix 10.14.101.0 255.255.255.0
    next
```

```

        edit 2
            set prefix 10.14.201.0 255.255.255.0
        next
        edit 3
            set prefix 10.14.202.0 255.255.255.0
        next
    end
    set passive-interface "port1"
    config interface
        edit "port1"
            set receive-version 2
            set send-version 2
        next
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
            set receive-version 2
            set send-version 2
        next
    end
end
end

```

Verifying the configuration

The interface's names are shown in the debugs. The same commands should also be run on the other routers.

To verify the configuration after the ISP router, Router2, and Router3 have been configured:

This verification can be done after the ISP router, Router2, and Router3 have been configured. Only Router2's debugs are shown.

1. Check the RIP interface information:

```

# get router info rip interface
Router2 is up, line protocol is up
  RIP is not enabled on this interface
ssl.Router2 is up, line protocol is up
  RIP is not enabled on this interface
vdr2link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      172.20.120.102/24
vd12link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.201.102/24

```

```

vd42link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.14.201.102/24
vd23link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.12.101.102/24

```

RIP starts exchanging routes as soon as the networks are added to the Router2 and Router3 configurations because the RIP interfaces are active by default, and start sending and receiving RIP updates when a matching interface on the subnet is found. The interface configuration allows the interface settings to be fine tuned, in this case to specify only RIPv2 support.

2. Check the RIP database:

```

# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP

```

	Network	Next Hop	Metric	From	If	Time
R	0.0.0.0/0	172.20.120.5	2	172.20.120.5	vdr2link1	02:55
Rc	10.11.201.0/24		1		vd12link1	
R	10.11.202.0/24	10.12.101.103	2	10.12.101.103	vd23link0	02:33
Rc	10.12.101.0/24		1		vd23link0	
Rc	10.14.201.0/24		1		vd42link1	
R	10.14.202.0/24	10.12.101.103	2	10.12.101.103	vd23link0	02:33
Rc	172.20.120.0/24		1		vdr2link1	
R	172.20.121.0/24	10.12.101.103	2	10.12.101.103	vd23link0	02:33

3. Check the routing table:

```

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

```

Routing table for VRF=0

```

R*    0.0.0.0/0 [120/2] via 172.20.120.5, vdr2link1, 13:37:23
C     10.11.201.0/24 is directly connected, vd12link1
R     10.11.202.0/24 [120/2] via 10.12.101.103, vd23link0, 14:10:01
C     10.12.101.0/24 is directly connected, vd23link0
C     10.14.201.0/24 is directly connected, vd42link1
R     10.14.202.0/24 [120/2] via 10.12.101.103, vd23link0, 14:10:01
C     172.20.120.0/24 is directly connected, vdr2link1
R     172.20.121.0/24 [120/2] via 10.12.101.103, vd23link0, 13:20:36

```

Router2 has learned the default gateway from the ISP router, and has learned of other networks from Router3.

4. If firewall policies are correctly configured, the outside network can be reached:

```
# execute ping-options source 10.11.201.102
# execute ping 8.8.8.8
PING 8.8.8.8 (8.8.8.8): 56 data bytes
64 bytes from 8.8.8.8: icmp_seq=0 ttl=115 time=4.5 ms
64 bytes from 8.8.8.8: icmp_seq=1 ttl=115 time=4.2 ms
64 bytes from 8.8.8.8: icmp_seq=2 ttl=115 time=4.2 ms

 3  * * *
```

To verify the configuration after Router1 and Router4 have also been configured:

This verification can be done after Router1 and Router4 have been configured. Only Router1's debugs are shown.

1. Check the RIP interface information:

```
# get router info rip interface
Router1 is up, line protocol is up
  RIP is not enabled on this interface
ssl.Router1 is up, line protocol is up
  RIP is not enabled on this interface
vd12link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.201.101/24
vd13link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.202.101/24
LoSales is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Enabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.101.101/24
      127.0.0.1/8
```

2. Check the RIP database:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
Network      Next Hop      Metric From      If      Time
R 0.0.0.0/0   10.11.202.103      3 10.11.202.103   vd13link0 02:35
Rc 10.11.101.0/24      1      LoSales
Rc 10.11.201.0/24      1      vd12link0
Rc 10.11.202.0/24      1      vd13link0
R 10.12.101.0/24   10.11.202.103      2 10.11.202.103   vd13link0 02:35
R 10.14.101.0/24   10.11.202.103      3 10.11.202.103   vd13link0 02:35
R 10.14.201.0/24   10.11.201.102      2 10.11.201.102   vd12link0 02:30
R 10.14.202.0/24   10.11.202.103      2 10.11.202.103   vd13link0 02:35
R 172.20.120.0/24  10.11.201.102      2 10.11.201.102   vd12link0 02:30
R 172.20.121.0/24  10.11.202.103      2 10.11.202.103   vd13link0 02:35
```

3. Check the routing table:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
R* 0.0.0.0/0 [120/3] via 10.11.202.103, vd13link0, 00:09:42
C 10.11.101.0/24 is directly connected, LoSales
C 10.11.201.0/24 is directly connected, vd12link0
C 10.11.202.0/24 is directly connected, vd13link0
R 10.12.101.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
R 10.14.101.0/24 [120/3] via 10.11.202.103, vd13link0, 00:09:42
R 10.14.201.0/24 [120/2] via 10.11.201.102, vd12link0, 00:09:42
R 10.14.202.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
R 172.20.120.0/24 [120/2] via 10.11.201.102, vd12link0, 00:09:42
R 172.20.121.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
```

4. If firewall policies are correctly configured, the accounting network and the internet are reachable from the sales network:

```
# execute ping-options source 10.11.101.101
# execute ping 10.14.101.104
PING 10.14.101.104 (10.14.101.104): 56 data bytes
64 bytes from 10.14.101.104: icmp_seq=0 ttl=254 time=0.1 ms
64 bytes from 10.14.101.104: icmp_seq=1 ttl=254 time=0.0 ms
64 bytes from 10.14.101.104: icmp_seq=2 ttl=254 time=0.0 ms
64 bytes from 10.14.101.104: icmp_seq=3 ttl=254 time=0.0 ms
64 bytes from 10.14.101.104: icmp_seq=4 ttl=254 time=0.0 ms
--- 10.14.101.104 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.0/0.0/0.1 ms

# execute traceroute 10.14.101.104
traceroute to 10.14.101.104 (10.14.101.104), 32 hops max, 3 probe packets per hop, 84
byte packets
 1 10.11.202.103 0.079 ms 0.029 ms 0.013 ms
 2 10.14.101.104 0.043 ms 0.020 ms 0.010 ms
```

```
# execute ping 8.8.8.8
PING 8.8.8.8 (8.8.8.8): 56 data bytes
64 bytes from 8.8.8.8: icmp_seq=0 ttl=114 time=4.3 ms
64 bytes from 8.8.8.8: icmp_seq=1 ttl=114 time=4.1 ms
--- 8.8.8.8 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max = 4.1/4.2/4.3 ms

# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.11.202.103  0.094 ms  0.036 ms  0.030 ms
 2  172.20.121.5   0.216 ms  0.045 ms  0.038 ms
```

Testing the configuration and routing changes

After the network is configured, test it to ensure that when network events occur, such as a downed link, routing updates are triggered and converge as expected.

In the following examples, we disable certain links to simulate network outages, then verify that routing and connectivity is restored after the updates have converged.

Example 1 - ISP router port3 interface goes down

In this example, a link outage occurs on port3 of the ISP router. Consequently, all routers must use Router2, and not Router3, to reach the internet. Note the RIP database before and after the link failure, and the time taken for the route updates to propagate and return to a functioning state.

Router4's debugs are shown.

Before:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,

 3  * * *

```

After:

- You might see different routes, and the routes might change, while convergence is occurring. During convergence, the metric for your default route increases to 16.

```

# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network      Next Hop      Metric From      If      Time
R  0.0.0.0/0     10.14.202.103      16 10.14.202.103  vd43link0 01:50

```

- After convergence is complete, the RIP database will look similar to the following:

```

# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network      Next Hop      Metric From      If      Time
R  0.0.0.0/0     10.14.201.102       3 10.14.201.102  vd42link0 02:53
R  10.11.101.0/24 10.14.202.103       3 10.14.202.103  vd43link0 03:00
R  10.11.201.0/24 10.14.201.102       2 10.14.201.102  vd42link0 02:53
R  10.11.202.0/24 10.14.202.103       2 10.14.202.103  vd43link0 03:00
R  10.12.101.0/24 10.14.202.103       2 10.14.202.103  vd43link0 03:00
Rc 10.14.101.0/24          1      LoAccounting
Rc 10.14.201.0/24          1      vd42link0
Rc 10.14.202.0/24          1      vd43link0
R  172.20.120.0/24 10.14.201.102       2 10.14.201.102  vd42link0 02:53

```

- The default router should point to Router2, with the same number of hops:

```

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
R*  0.0.0.0/0 [120/3] via 10.14.201.102, vd42link0, 00:05:24
R    10.11.101.0/24 [120/3] via 10.14.202.103, vd43link0, 02:58:13
R    10.11.201.0/24 [120/2] via 10.14.201.102, vd42link0, 02:58:39

C    10.14.201.0/24 is directly connected, vd42link0

```

```

C      10.14.202.0/24 is directly connected, vd43link0
R      172.20.120.0/24 [120/2] via 10.14.201.102, vd42link0, 02:58:39

# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.14.201.102  0.167 ms  0.063 ms  0.029 ms
 2  172.20.120.5   0.117 ms  0.073 ms  0.041 ms
 3  172.16.151.1   0.303 ms  0.273 ms  0.253 ms

```

Example 2- Additional link failures on Router2

In addition to the link failure on the ISP router in example, port1 and port3 on Router2 have also failed. This means that Router4 must go through Router3, Router1, Router2, then the ISP router to reach the internet. Note that, for a period of time, some routes' metrics increase to 16. If no better routes are found for these networks, then they eventually disappear.

After the convergence completes, the RIP database and routing table on Router4 should resemble the following:

```

# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network      Next Hop      Metric From      If      Time
R  0.0.0.0/0     10.14.202.103      5 10.14.202.103   vd43link0 02:54
R  10.11.101.0/24 10.14.202.103      3 10.14.202.103   vd43link0 02:54
R  10.11.201.0/24 10.14.202.103      3 10.14.202.103   vd43link0 02:54
R  10.11.202.0/24 10.14.202.103      2 10.14.202.103   vd43link0 02:54
Rc 10.14.101.0/24      1                  LoAccounting
Rc 10.14.202.0/24      1                  vd43link0
R  172.20.120.0/24 10.14.202.103      4 10.14.202.103   vd43link0 02:54

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
R*   0.0.0.0/0 [120/5] via 10.14.202.103, vd43link0, 00:03:54
R    10.11.101.0/24 [120/3] via 10.14.202.103, vd43link0, 03:10:12
R    10.11.201.0/24 [120/3] via 10.14.202.103, vd43link0, 00:03:54
R    10.11.202.0/24 [120/2] via 10.14.202.103, vd43link0, 03:10:38

R    172.20.120.0/24 [120/4] via 10.14.202.103, vd43link0, 00:03:54

```

Reaching the internet on the default gateway now requires five hops from Router4:

```

# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.14.202.103  0.087 ms  0.026 ms  0.012 ms
 2  10.11.202.101  0.045 ms  0.024 ms  0.025 ms
 3  10.11.201.102  0.048 ms  0.024 ms  0.015 ms
 4  172.20.120.5   0.050 ms  0.028 ms  0.019 ms
 5  * * *

```

Basic RIPng example

In this example, a small network is configured with RIP next generation (RIPng). Two FortiGates are connected to the internal network and the ISP, providing some redundancy to help ensure that the internal network can always reach the internet.

The FortiGates are running in NAT mode with VDOMs disabled, and firewall policies have already been configured to allow traffic to flow across the interfaces.

All of the internal computers and other network devices support IPv6 addressing and are running RIPng (where applicable), so no static routing is required. Internal network devices only need to know the FortiGate's internal interface network addresses.

Router	Interface (alias)	IPv6 address
Router1	port1 (internal)	2002:A0B:6565:0:0:0:0
	port2 (ISP)	2002:AC14:7865:0:0:0:0
Router2	port1 (internal)	2002:A0B:6566:0:0:0:0
	port2 (ISP)	2002:AC14:7866:0:0:0:0

On each FortiGate, the interfaces are configured first, and then RIPng. No redistribution or authentication is configured.

In the RIPng configuration, only the interface names are required. The ISP router and the other FortiGate are configured as neighbors. Declaring the neighbors reduces the discovery traffic when the routers start. There is no specific command to include a subnet in the RIP broadcast, and RIPng can only be configured using the CLI.

To configure Router1:

1. Configure the interfaces:

```
config system interface
  edit port1
    set allowaccess ping https ssh
    set type physical
    set description "Internal RnD network"
    set alias "internal"
    config ipv6
      set ip6-address 2002:a0b:6565::/0
    end
  end
```

```

    next
    edit port2
        set allowaccess ping https ssh
        set type physical
        set description "ISP and Internet"
        set alias "ISP"
        config ipv6
            set ip6-address 2002:ac14:7865::/0
        end
    next
end

```

2. Configure RIPng:

```

config router ripng
    config neighbor
        edit 1
            set ip6 2002:a0b:6566::
            set interface port1
        next
        edit 2
            set ip6 2002:ac14:7805::
            set interface port2
        next
    end
config interface
    edit port1
    next
    edit port2
    next
end
end

```

To configure Router2:

1. Configure the interfaces:

```

config system interface
    edit port1
        set allowaccess ping https ssh
        set type physical
        set description "Internal RnD network"
        set alias "internal"
        config ipv6
            set ip6-address 2002:a0b:6566::/0
        end
    next
    edit port2
        set allowaccess ping https ssh
        set type physical
        set description "ISP and Internet"
        set alias "ISP"
        config ipv6
            set ip6-address 2002:ac14:7866::/0
        end
    next
end

```

2. Configure RIPng:

```
config router ripng
  config neighbor
    edit 1
      set ip6 2002:a0b:6565::
      set interface port1
    next
  edit 2
    set ip6 2002:ac14:7805::
    set interface port2
  next
end
config interface
  edit port1
  next
  edit port2
  next
end
end
```

Testing the configuration

The following commands can be used to check the RIPng information on the FortiGates, and can help track down issues:

To view the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate:

```
# diagnose ipv6 address list
```

To view IPv6 addresses that are installed in the routing table:

```
# diagnose ipv6 route list
```

To view the IPv6 routing table:

```
# get router info6 routing-table
```

This information is similar to the `diagnose ipv6 route list` command, but it is presented in an easier to read format.

To view the brief output on the RIP information for the interface listed:

```
# get router info6 rip interface external
```

This includes information such as, if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon is enabled.

OSPF

Open Shortest Path First (OSPF) is a link state routing protocol that is commonly used in large enterprise networks with L3 switches, routers, and firewalls from multiple vendors. It can quickly detect link failures, and converges network traffic

without networking loops. It also has features to control which routes are propagated, allowing for smaller routing tables, and provides better load balancing on external links when compared to other routing protocols.

To configure OSPF in the GUI, go to *Network > OSPF*:

Option	Description
Router ID	A unique ID to identify your router in the network, typically in the format x.x.x.x.
Areas	The areas that the router is part of. For each area, define the <i>Area ID</i> , <i>Type</i> , and <i>Authentication</i> method.
Networks	The networks that OSPF is enabled in, and the area that they belong to.
Interfaces	OSPF interfaces for transmitting and receiving packets. Configure interface properties, such as <i>Network Type</i> , <i>Cost</i> , <i>Hello interval</i> , and others.
Advanced Options	Settings for <i>Inject Default Route</i> , <i>Passive Interfaces</i> , and <i>Redistribute</i> . Redistribution can be enabled by protocol and the metric for each protocol can be configured.

This section includes the following topics:

- [Basic OSPF example on page 452](#)
- [OSPFv3 neighbor authentication on page 463](#)
- [OSPF graceful restart upon a topology change on page 465](#)

Basic OSPF example

In this example, three FortiGate devices are configured in an OSPF network.

- Router1 is the Designated Router (DR). It has the highest priority and the lowest IP address, to ensure that it becomes the DR.
- Router2 is the Backup Designated Router (BDR). It has a high priority to ensure that it becomes the BDR.
- Router3 is the Autonomous System Border Router (ASBR). It routes all traffic to the ISP BGP router for internet access. It redistributes routes from BGP and advertises a default route to its neighbors. It can allow different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics can be assigned to these routes to make them more or less preferred than regular OSPF routes. Route maps could be used to further control what prefixes are advertised or received from the ISP.

FortiGate	Interface	IP address
Router1 (DR)	port1	10.11.101.1
	port2	10.11.102.1
	port3	192.168.102.1
Router2 (BDR)	port1	10.11.101.2
	port2	10.11.103.2
	port3	192.168.103.2
Router3 (ASBR)	port1	10.11.102.3
	port2	10.11.103.3
	port3	172.20.120.3

- Firewall policies are already configured to allow unfiltered traffic in both directions between all of the connected interfaces.
- The interfaces are already configured, and NAT is only used for connections to public networks. The costs for all of the interfaces is left at 0.
- The OSPF network belongs to Area 0, and is not connected to any other OSPF networks. All of the routers are part of the backbone 0.0.0.0 area, so no inter-area communications are needed.
- Router3 redistributes BGP routes into the OSPF AS and peers with the ISP BGP Router over eBGP. For information about configuring BGP, see [BGP on page 468](#).
- The advertised networks - 10.11.101.0, 10.11.102.0, and 10.11.103.0 - are summarized by 10.11.0.0/16. Additional networks are advertised individually by the /24 subnet.

Router1

To configure Router1 in the GUI:

1. Go to *Network > OSPF*.
2. Set *Router ID* to *10.11.101.1*.
3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.
5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

6. Click *OK*.
7. In the *Networks* table, click *Create New* again and set the following:

Area	0.0.0.0
IP/Netmask	192.168.102.0 255.255.255.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router1-Internal-DR
Interface	port1
Cost	0
Priority	255
Authentication	None
Timers	<ul style="list-style-type: none"> • Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router1-External
Interface	port2
Cost	0
Authentication	None
Timers	<ul style="list-style-type: none"> • Hello Interval: 10 • Dead Interval: 40

12. Click *OK*.
13. Click *Apply*.

To configure Router1 in the CLI:

```
config router ospf
  set router-id 10.11.101.1
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit "Router1-Internal-DR"
      set interface "port1"
      set priority 255
      set dead-interval 40
      set hello-interval 10
    next
    edit "Router1-External"
      set interface "port2"
      set dead-interval 40
      set hello-interval 10
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0 255.255.0.0
    next
    edit 2
      set prefix 192.168.102.0 255.255.255.0
    next
  end
end
```

Router2

To configure Router2 in the GUI:

1. Go to *Network > OSPF*.
2. Set *Router ID* to *10.11.101.2*.
3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.
5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

6. Click *OK*.
7. In the *Networks* table, click *Create New* again and set the following:

Area	0.0.0.0
IP/Netmask	192.168.103.0 255.255.255.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router2-Internal
Interface	port1
Cost	0
Priority	250
Authentication	None
Timers	<ul style="list-style-type: none">Hello Interval: 10Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router2-External
Interface	port2
Cost	0
Authentication	None
Timers	<ul style="list-style-type: none">Hello Interval: 10Dead Interval: 40

12. Click *OK*.
13. Click *Apply*.

To configure Router2 in the CLI:

```
config router ospf
  set router-id 10.11.101.1
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit "Router2-Internal"
    set interface "port1"
    set priority 250
    set dead-interval 40
    set hello-interval 10
  next
  edit "Router2-External"
    set interface "port2"
```

```

        set dead-interval 40
        set hello-interval 10
    next
end
config network
    edit 1
        set prefix 10.11.0.0 255.255.0.0
    next
    edit 2
        set prefix 192.168.103.0 255.255.255.0
    next
end
end

```

Router3

To configure Router3 in the GUI:

1. Go to *Network > OSPF*.
2. Set *Router ID* to *10.11.103.3*.
3. Under *Default Settings*, set *Inject default route to Regular Areas*.
A default route must be present on Router3 to advertise it to other routers.
4. Enable *Redistribute BGP* and use the default settings.
5. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

6. Click *OK*.
7. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router3-Internal
Interface	port1
Cost	0
Authentication	None
Timers	<ul style="list-style-type: none"> • Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router3-Internal2
Interface	port2
Cost	0
Authentication	None
Timers	<ul style="list-style-type: none">• Hello Interval: 10• Dead Interval: 40

12. Click *OK*.

13. Click *Apply*.

To configure Router3 in the CLI:

```
config router ospf
  set default-information-originate enable
  set router-id 10.11.103.3
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit "Router3-Internal"
      set interface "port1"
      set dead-interval 40
      set hello-interval 10
    next
    edit "Router3-Internal2"
      set interface "port2"
      set dead-interval 40
      set hello-interval 10
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0 255.255.0.0
    next
  end
  config redistribute "bgp"
    set status enable
  end
end
```

To configure BGP on Router3 in the CLI:

```
config router bgp
  set as 64511
  set router-id 1.1.1.1
  config neighbor
    edit "172.20.120.5"
      set remote-as 64512
    next
  end
  config network
```

```

        edit 1
            set prefix 172.20.120.0 255.255.255.0
        next
    end
end

```

For more information on configuring BGP, see [BGP on page 468](#).

Testing the configuration

Both the network connectivity and OSPF routing are tested. When a link goes down, routes should converge as expected.

Working state

- Router3:

```

Router3 # get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID      Pri   State           Dead Time   Address        Interface
10.11.101.1      1    Full/Backup     00:00:34   10.11.102.1    port1
10.11.101.2      1    Full/Backup     00:00:38   10.11.103.2    port2

Router3 # get router info ospf status
Routing Process "ospf 0" with ID 10.11.103.3
Process uptime is 18 hours 52 minutes
Process bound to VRF default
Conforms to RFC2328, and RFC1583Compatibility flag is disabled
Supports only single TOS(TOS0) routes
Supports opaque LSA
Do not support Restarting
This router is an ASBR (injecting external routing information)
SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
Refresh timer 10 secs
Number of incoming current DD exchange neighbors 0/5
Number of outgoing current DD exchange neighbors 0/5
Number of external LSA 3. Checksum 0x021B78
Number of opaque AS LSA 0. Checksum 0x000000
Number of non-default external LSA 2
External LSA database is unlimited.
Number of LSA originated 16
Number of LSA received 100
Number of areas attached to this router: 1
    Area 0.0.0.0 (BACKBONE)
        Number of interfaces in this area is 2(2)
        Number of fully adjacent neighbors in this area is 2
        Area has no authentication
        SPF algorithm last executed 00:37:36.690 ago
        SPF algorithm executed 13 times
        Number of LSA 6. Checksum 0x03eafa

Router3 # get router info routing-table all

OSPFv3 neighbor authentication

OSPFv3 neighbor authentication is available for enhanced IPv6 security.

To configure an OSPF6 interface:

```

config router ospf6
  config ospf6-interface
    edit <name>
      set authentication {none | ah | esp | area}
      set key-rollover-interval <integer>
      set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
      set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
      config ipsec-keys
        edit <spi>
          set auth-key <string>
          set enc-key <string>
        next
      end
    next
  end
end

```

To configure an OSPF6 virtual link:

```

config router ospf6
  config area
    edit <id>
      config virtual-link
        edit <name>
          set authentication {none | ah | esp | area}
          set key-rollover-interval <integer>
          set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
          set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
          config ipsec-keys
            edit <spi>
              set auth-key <string>
              set enc-key <string>
            next
          end
        next
      end
    next
  end
end

```

To configure an OSPF6 area:

```

config router ospf6
  config area
    edit <id>
      set authentication {none | ah | esp}
      set key-rollover-interval <integer>
      set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
      set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
      config ipsec-keys
        edit <spi>
          set auth-key <string>
          set enc-key <string>
        next
      end
    next
  end
end

```

CLI command descriptions

Command	Description
<id>	Area entry IP address.
authentication {none ah esp area}	Authentication mode: <ul style="list-style-type: none"> • none: Disable authentication • ah: Authentication Header • esp: Encapsulating Security Payload • area: Use the routing area authentication configuration
key-rollover-interval <integer>	Enter an integer value (300 - 216000, default = 300).
ipsec-auth-alg {md5 sha1 sha256 sha384 sha512}	Authentication algorithm.
ipsec-enc-alg {null des 3des aes128 aes192 aes256}	Encryption algorithm.
<spi>	Security Parameters Index.
auth-key <string>	Authentication key should be hexadecimal numbers. Key length for each algorithm: <ul style="list-style-type: none"> • MD5: 16 bytes • SHA1: 20 bytes • SHA256: 32 bytes • SHA384: 48 bytes • SHA512: 64 bytes If the key is shorter than the required length, it will be padded with zeroes.
enc-key <string>	Encryption key should be hexadecimal numbers. Key length for each algorithm: <ul style="list-style-type: none"> • DES: 8 bytes • 3DES: 24 bytes

Command	Description
	<ul style="list-style-type: none"> • AES128: 16 bytes • AES192: 24 bytes • AES256: 32 bytes <p>If the key is shorter than the required length, it will be padded with zeroes.</p>

OSPF graceful restart upon a topology change

In OSPF graceful restart mode, the `restart-on-topology-change` option can be used to keep restarting the router in graceful restart mode when a topology change is detected during a restart.

```
config router ospf
    set restart-on-topology-change {enable | disable}
end
```

OSPFv3 graceful restart mode upon a topology change can be used in OSPF6:

```
config router ospf6
    set restart-on-topology-change {enable | disable}
end
```

Example

In this example, a restarting router (one of the FG-300Es in the HA cluster) informs its neighbors using grace LSAs before restarting its OSPF process. When the helper router (the FG-601E) receives the grace LSAs, it enters helper mode to help with the graceful restart until the graceful period expires. It will act as though there are no changes on the restarting router (FG-300E). A generic router simulates a topology change during the restart event.

If `restart-on-topology-change` is enabled on the restarting router, it will not exit the graceful restart mode even when a topology change is detected.

If `restart-on-topology-change` is disabled on the restarting router, it will exit graceful restart mode when a topology change is detected.

To configure the restarting router:

```

config router ospf
    set router-id 31.1.1.1
    set restart-mode graceful-restart
    set restart-period 180
    set restart-on-topology-change enable
config area
    edit 0.0.0.0
    next
end
config network
    edit 1
        set prefix 172.16.200.0 255.255.255.0
    next
    edit 2
        set prefix 31.1.1.1 255.255.255.255
    next
end
end

```

To configure the restarting helper router:

```

config router ospf
    set router-id 3.3.3.3
    set restart-mode graceful-restart
config area
    edit 0.0.0.0
    next
end
config network
    edit 1
        set prefix 172.16.200.0 255.255.255.0
    next
    edit 2
        set prefix 3.3.3.3 255.255.255.255
    next
end
end

```

Testing the configuration**Topology change with continuing graceful restart enabled:**

When `restart-on-topology-change` is enabled and there is a topology change during the HA OSPF graceful restart, the graceful restart will continue. The routes on the helper router (FG-601E) are still there and no traffic will drop.

```

# get router info ospf neighbor

```

BGP

Border Gateway Protocol (BGP) is a standardized routing protocol that is used to route traffic across the internet. It exchanges routing information between Autonomous Systems (AS) on the internet and makes routing decisions based on path, network policies, and rule sets. BGP contains two distinct subsets: internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect different networks together and is the main routing protocol for the internet backbone.

To configure BGP in the GUI, go to *Network > BGP*:

Option	Description
Local AS	The AS number for the local router.
Router ID	A unique ID to identify your router in the network, typically in the format x.x.x.x.
Neighbors	The neighbors that the FortiGate will be peering with. Configure the remote router's AS number, any other properties used for peering with the neighbor, and IPv4 and IPv6 filtering.
Neighbor Groups	The neighbor groups that share the same outbound policy configurations.
Neighbor Ranges	The source address range of BGP neighbors that will be automatically assigned to a neighbor group.

Option	Description
IPv4 & IPv6 Networks	The networks to be advertised to other BGP routers.
IPv4 & IPv6 Redistribute	Enable redistribution by protocol. Specify either <i>All</i> routes, or <i>Filter</i> by route map.
Dampening	Enable route flap dampening to reduce the propagation of flapping routes.
Graceful Restart	Enable BGP graceful restart, which causes the adjacent routers to keep routes active while the BGP peering is restarted on the FortiGate. This is useful in HA instances when failover occurs.
Advanced Options	Various advanced settings, such as <i>Local Preference</i> , <i>Distance internal</i> , <i>Keepalive</i> , <i>Holdtime</i> , and others
Best Path Selection	Configure path selection attributes on this router.

Currently, FortiGates do not support BGP graceful restart when peering with neighbor routers operating in graceful restart helper-only mode.

This section includes the following topics:

- [Basic BGP example on page 469](#)
- [Route filtering with a distribution list on page 478](#)
- [Next hop recursive resolution using other BGP routes on page 482](#)
- [Next hop recursive resolution using ECMP routes on page 483](#)
- [BGP conditional advertisement on page 484](#)
- [BGP error handling per RFC 7606 on page 497](#)
- [BGP next hop tag-match mode on page 499](#)
- [BGP neighbor password on page 504](#)
- [Defining a preferred source IP for local-out egress interfaces on BGP routes on page 505](#)
- [BGP multi-exit discriminator on page 508](#)
- [Troubleshooting BGP on page 512](#)

Basic BGP example

In this example, BGP is configured on two FortiGate devices. The FortiGates are geographically separated, and form iBGP peering over a VPN connection. FGT_A also forms eBGP peering with ISP2.

FGT_A learns routes from ISP2 and redistributes them to FGT_B while preventing any iBGP routes from being advertised.

The internal networks behind the FortiGates can communicate with each other, and the internal networks behind FGT_B can traverse FGT_A to reach networks that are advertised by ISP2.

- FGT_A and FGT_B have static routes to each other through ISP1. ISP1 does not participate in BGP.
- The IPsec VPN tunnel between FGT_A and FGT_B is configured with wildcard 0.0.0.0/0 networks for phase2 local and remote selectors. The VPN interfaces have IP addresses already configured and are used for peering between FGT_A and FGT_B.
- FGT_A is configure to peer with ISP2 on 10.10.108.86.
- The firewall policies between FGT_A and FGT_B are not NATed. The firewall policies egressing on wan2 are NATed.

Configuring iBGP peering

To configure FGT_A to establish iBGP peering with FGT_B in the GUI:

1. Go to *Network > BGP*.
2. Set *Local AS* to 64511
3. Set *Router ID* to 1.1.1.1.
4. In the *Neighbors* table, click *Create New* and set the following:

IP	10.100.201.88
Remote AS	64511

5. Click *OK*.
6. Under *Networks*, set *IP/Netmask* to 192.168.86.0/24.
7. Click *Apply*.
8. In the CLI, set the interface used as the source IP address of the TCP connection (where the BGP session, TCP/179, is connecting from) for the neighbor (*update-source*) to toFGTB.

To configure FGT_A to establish iBGP peering with FGT_B in the CLI:

```
config router bgp
  set as 64511
  set router-id 1.1.1.1
  config neighbor
    edit "10.100.201.88"
      set remote-as 64511
      set update-source "toFGTB"
    next
  end
```

```

config network
  edit 1
    set prefix 192.168.86.0 255.255.255.0
  next
end
end

```

To configure FGT_B to establish iBGP peering with FGT_A in the GUI:

1. Go to *Network > BGP*.
2. Set *Local AS* to *64511*
3. Set *Router ID* to *2.2.2.2*.
4. In the *Neighbors* table, click *Create New* and set the following:

IP	10.100.201.86
Remote AS	64511

5. Click *OK*.
6. Under *Networks*, set *IP/Netmask* to *192.168.88.0/24*.
7. Click *Apply*.
8. In the CLI, set the interface used as the source IP address of the TCP connection (where the BGP session, TCP/179, is connecting from) for the neighbor (*update-source*) to *toFGTA*.

To configure FGT_B to establish iBGP peering with FGT_A in the CLI:

```

config router bgp
  set as 64511
  set router-id 2.2.2.2
  config neighbor
    edit "10.100.201.86"
      set remote-as 64511
      set update-source "toFGTA"
    next
  end
  config network
    edit 1
      set prefix 192.168.88.0 255.255.255.0
    next
  end
end
end

```

To check the FGT_A and FGT_B peering:

1. Check the BGP neighbors:

```
# get router info bgp neighbors
```
2. Check the networks learned from neighbors:

```
# get router info bgp network
```
3. Check that the routes are added to the routing table:

```
# get router info routing-table all
```

To see the neighborhood status, network, and routing table command outputs for the completed example, see [Troubleshooting and debugging on page 474](#).

Configuring eBGP peering

By establishing eBGP peering with ISP2, learned routes will have a distance of 20 and will automatically be propagated to iBGP peers. iBGP peers do not change the next hop when they advertise a route. To make FGT_B receive a route with FGT_A as the next hop, and not ISP 2's network, *Next hop self* (`next-hop-self`) is enabled for routes advertised to FGT_B.

Additionally, to peer with another router that is multiple hops away, enable `ebg-enforce-multihop` in the neighbor configuration.

In this example, the iBGP routes are automatically advertised to the eBGP neighbor, so a route map is created to deny iBGP routes from being advertised to ISP 2. Prefixes from ISP 2 are advertised to FGT_A and FGT_B, but no prefixes are advertised from FGT_A to ISP 2.

To configure FGT_A to establish eBGP peering with ISP 2 in the GUI:

1. Configure a route map to prevent advertisement of iBGP routes to ISP 2:
 - a. Go to *Network > Routing Objects* and click *Create New > Route Map*.
 - b. Set *Name* to *exclude1*.
 - c. In the *Rules* table, click *Create New*.
 - d. Set *Action* to *Deny*.
 - e. Under *Other Rule Variables*, enable *Match origin* and set it to *IGP*.
 - f. Click *OK*.
 - g. Click *OK*.
2. Update the BGP configuration:
 - a. Go to *Network > BGP*.
 - b. In the *Neighbors* table, click *Create New* and set the following:

IP	10.10.102.87
Remote AS	64512
Route map out	exclude1

- c. Click *OK*.
- d. In the *Neighbors* table, edit the previously created entry, *10.100.201.88*.
- e. Under *IPv4 Filtering*, select *Next hop self*.
- f. Click *OK*.
- g. Click *Apply*.

To configure FGT_A to establish eBGP peering with ISP 2 in the CLI:

1. Configure a route map to prevent advertisement of iBGP routes to ISP 2:

```
config router route-map
  edit "exclude1"
    config rule
      edit 1
```

```

        set action deny
        set match-origin igp
    next
end
next
end

```

2. Update the BGP configuration:

```

config router bgp
  config neighbor
    edit "10.10.102.87"
      set remote-as 64512
      set route-map-out "excludel"
    next
    edit "10.100.201.88"
      set next-hop-self enable
    next
  end
end

```

To see the neighborhood status, network, and routing table command outputs for the completed example, see [Troubleshooting and debugging on page 474](#).

Firewall policies

On FGT_A configure the following policies:

- Allow the internal subnet to the VPN interface. Do not enable NAT. Enable security profiles as required.
- Allow the VPN interface to the internal subnet. Do not enable NAT. Enable security profiles as required.
- Allow the internal subnet to wan2. Enable NAT and security profiles as required.
- Allow VPN traffic from toFGTA to wan2. Enable NAT and security profiles as required.

On FGT_B configure the following policies:

- Allow the internal subnet to the VPN interface. Do not enable NAT. Enable security profiles as required.
- Allow the VPN interface to the internal subnet. Do not enable NAT. Enable security profiles as required.

To verify that pinging from FGT_B to FGT_A is successful:

```

FGT_B # execute ping-options source 192.168.88.88
FGT_B # execute ping 192.168.86.86
PING 192.168.86.86 (192.168.86.86): 56 data bytes
64 bytes from 192.168.86.86: icmp_seq=0 ttl=255 time=0.5 ms
...
--- 192.168.86.86 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.3/0.3/0.5 ms

```

To verify that pinging from FGT_B to a subnet in ISP 2 is successful:

```

FGT_B # execute ping-options source 192.168.88.88
FGT_B # execute ping 172.16.201.87
PING 172.16.201.87 (172.16.201.87): 56 data bytes
64 bytes from 172.16.201.87: icmp_seq=0 ttl=254 time=0.6 ms
...

```

```

--- 172.16.201.87 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.4/0.4/0.6 ms

FGT_B # execute traceroute-options source 192.168.88.88
FGT_B # execute traceroute 172.16.201.87
traceroute to 172.16.201.87 (172.16.201.87), 32 hops max, 3 probe packets per hop, 84 byte
packets
 1  10.100.201.86  0.315 ms  0.143 ms  0.110 ms
 2  172.16.201.87  0.258 ms  0.144 ms  0.222 ms

```

Troubleshooting and debugging

When troubleshooting issues, logically step through the debugs. For example, if peering cannot be established between FGT_A and FGT_B:

1. Verify the basic connectivity between the FGT_A wan1 interface and the FGT_B port1 interface.
2. Verify that the VPN between FGT_A and FGT_B is established.
3. Verify the connectivity between the VPN interfaces.
4. Check the neighborhood status on each peer. Use the BGP state to help determine the possible issue, for example:

Idle state	The local FortiGate has not started the BGP process with the neighbor. This could be because the eBGP peer is multiple hops away, but multihop is not enabled.
Connect	The local FortiGate has started the BGP process, but has not initiated a TCP connection, possibly due to improper routing.
Active	The local FortiGate has initiated a TCP connection, but there is no response. This might indicate issues with the delivery or the response from the remote peer.

5. If there are issues establishing the TCP connection, use the command `diagnose sniffer packet any 'tcp and port 179'` to identify the problem at the packet level.

The following outputs show instances where all of the configurations are completed, peering has formed, and routes have been exchanged. The debug output during each configuration step might differ from these outputs. These debug outputs can be used to help identify what might be missing or misconfigured on your device.

To verify the status of the neighbors:

```

FGT_A # get router info bgp neighbors
VRF 0 neighbor table:

```

Route filtering with a distribution list

During BGP operations, routes can be propagated between BGP peers and redistributed from other routing protocols. In some situations, advertising routes from one peer to another might need to be prevented.

The [Basic BGP example on page 469](#) explains using a route map to filter routes that are learned from iBGP to prevent them from propagating to an eBGP peer. In this example, a distribution list is used to prevent certain routes from one peer from being advertised to another peer.

- A company has its own web and email servers in an OSPF area, and needs to advertise routes to these resources to external peers. Users, routers, and other server all reside in the OSPF area.

- The FortiGate acts as the BGP border router, redistributing routes from the company's network to its BGP peers. It is connected to the OSPF area using its DMZ interface.
- Two ISP managed BGP peers in an AS (Peer 1 and Peer 2) are used to access the internet, and routes must not to be advertised from Peer 1 to Peer 2. The manufacturers of these routers, and information about other devices on the external BGP AS, are not known.
- Routes to the BGP peers are redistributed so that external locations can access the web and email servers in the OSPF area. The FortiGate device's external interfaces and the BGP peers are in different ASs, and form eBGP peers.
- Other networking devices must be configured for BGP. The peer routers must be updated with the FortiGate device's BGP information, including IP addresses, AS number, and any specific capabilities that are used, such as IPv6, graceful restart, BFD, and so on.
- It is assumed that security policies have been configured to allow traffic between the networks and NAT is not used. To tighten security, only the required services should be allowed inbound to the various servers.
- In a real life scenario, public IP addresses would be used in place of private IP addresses.

Configuring BGP

In this example, Peer 1 routes are blocked from being advertised to Peer 2 using an access list. All incoming routes from Peer 1 are blocked when updates are sent to Peer 2.

Routes learned from OSPF are redistributed into BGP. EBGp multi path is enabled to load-balance traffic between the peers using ECMP. See [Equal cost multi-path on page 421](#) for more information.

To configure BGP in the GUI:

1. Configure an access list to block Peer 1 routes:
 - a. Go to *Network > Routing Objects* and click *Create New > Access List*.
 - b. Set *Name* to *block_peer1*.
 - c. In the *Rules* table, click *Create New*.
 - d. Set *Action* to *Deny*.
 - e. Enable *Exact Match* and specify the prefix *172.21.111.0 255.255.255.0*.
 - f. Click *OK*.
 - g. Click *OK*.
2. Configure BGP:
 - a. Go to *Network > BGP*.
 - b. Set *Local AS* to *65001*.
 - c. Set *Router ID* to *10.11.201.110*.
 - d. In the *Neighbors* table, click *Create New* and set the following:

IP	172.21.111.5
Remote AS	65001

- e. Click *OK*.
- f. In the *Neighbors* table, click *Create New* again and set the following:

IP	172.22.222.5
----	--------------

Remote AS	65001
Distribute list out	Enable, and select the <i>block_peer1</i> access list.

- g. Click *OK*.
- h. Under *IPv4 Redistribute*, enable *OSPF* and select *ALL*.
- i. Expand *Best Path Selection* and enable *EBGP multi path*.
- j. Click *Apply*.

To configure BGP in the CLI:

1. Configure an access list to block Peer 1 routes:

```
config router access-list
    edit "block_peer1"
        config rule
            edit 1
                set action deny
                set prefix 172.21.111.0 255.255.255.0
                set exact-match enable
            next
        end
    next
end
```

2. Configure BGP:

```
config router bgp
    set as 65001
    set router-id 10.11.201.110
    set ebgp-multipath enable
    config neighbor
        edit "172.21.111.5"
            set remote-as 65001
        next
        edit "172.22.222.5"
            set distribute-list-out "block_peer1"
            set remote-as 65001
        next
    end
    config redistribute "ospf"
        set status enable
    end
end
```

Configuring OSPF

In this example, all of the traffic is within the one OSPF area, and there are other OSPF routers in the network. When adjacencies are formed, other routers receive the routes advertised from the FortiGate that are redistributed from BGP.

To configure OSPF in the GUI:

1. Go to *Network > OSPF*.
2. Set *Router ID* to *10.11.201.110*.

3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.

5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.201.0 255.255.255.0

6. Click *OK*.

7. In the *Interfaces* table, click *Create New* and set the following:

Name	OSPF_dmz_network
Interface	dmz

8. Click *OK*.

9. Enable *Redistribute BGP* and set *Metric value* to 1.

10. Click *Apply*.

To configure OSPF in the CLI:

```
config router ospf
  set router-id 10.11.201.110
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit "OSPF_dmz_network"
      set interface "dmz"
    next
  end
  config network
    edit 1
      set prefix 10.11.201.0 255.255.255.0
    next
  end
  config redistribute "bgp"
    set status enable
    set metric 1
  end
end
```

Testing the configuration

To test this configuration, run the standard connectivity checks, and also make sure that routes are being passed between protocols as expected. Use the following checklist to help verify that the FortiGate is configured successfully:

1. Check that the FortiGate has established peering with BGP Peer 1 and Peer 2:

```
# get router info bgp summary
# get router info bgp neighbors
```

2. Check that the FortiGate has formed adjacency with OSPF neighbors:

```
# get router info ospf status
# get router info ospf neighbors
```

3. Check the routing table on the FortiGate to make sure that routes from both OSPF and BGP are included:

```
# get router info routing-table all
```

4. Check devices in the OSPF network for internet connectivity and to confirm that routes redistributed from BGP are in their routing tables.
5. Check the routing table on Peer 2 to confirm that no routes from Peer 1 are included.
6. Check that the routes from the internal OSPF network are redistributed to Peer 1 and Peer 2.
7. Verify connectivity to the HTTP and email servers.

Next hop recursive resolution using other BGP routes

By default, BGP routes are not considered when a BGP next hop requires recursive resolution. They are considered when `recursive-next-hop` is enabled. Recursive resolution will resolve to one level.

To consider BGP routes for recursive resolution of next hops:

```
config router bgp
    set recursive-next-hop enable
end
```

Example

To see the change in the routing table when the option is enabled:

1. Check the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B      10.100.1.4/30 [200/0] via 10.100.1.14 (recursive is directly connected, R560),
00:02:06
```

2. Enable BGP routes for recursive resolution of next hops:

```
config router bgp
    set recursive-next-hop enable
end
```

3. Check the BGP routing table again:

```
# get router info routing-table bgp
Routing table for VRF=0
B      10.100.1.4/30 [200/0] via 10.100.1.14 (recursive is directly connected, R560),
00:02:15
B      172.16.203.0/24 [200/0] via 10.100.1.6 (recursive via 10.100.1.14, R560),
00:00:06
```

The second BGP route's next hop is now recursively resolved by another BGP route.

Next hop recursive resolution using ECMP routes

When there are multiple ECMP routes to a BGP next hop, all of them are considered for the next hop recursive resolution. This ensures that the outgoing traffic can be load balanced.

To support multipath, either EGBP or IGBP multipath must be enabled:

```
config router bgp
    set ebgp-multipath enable
    set ibgp-multipath enable
end
```

In this example, there are two static routes. The FortiGate has learned two BGP routes from Router 1 that have the same next hop at 10.100.100.1. The next hop is resolved by the two static routes.

To verify that the routes are added to the BGP routing table:

1. Check the two static routes:

```
# get router info routing-table static
Routing table for VRF=0
S      10.100.100.0/24 [10/0] via 172.16.200.55, port9
      [10/0] via 172.16.203.2, agg1
```

2. Confirm that both routes are in the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B      10.100.10.0/24 [20/200] via 10.100.100.1 (recursive via 172.16.200.55, port9),
00:00:07                                     (recursive via 172.16.203.2, agg1),
00:00:07
B      10.100.11.0/24 [20/200] via 10.100.100.1 (recursive via 172.16.200.55, port9),
00:00:07                                     (recursive via 172.16.203.2, agg1),
00:00:07
```

BGP conditional advertisement

BGP conditional advertisement allows the router to advertise a route only when certain conditions are met. Multiple conditions can be used together, with conditional route map entries treated as an AND operator, and IPv6 is supported.

Multiple conditions example

In this example, the FortiGate only advertises routes to its neighbor 2.2.2.2 if it learns multiple BGP routes defined in its conditional route map entry. All conditionals must be met.

To configure multiple conditions in BGP conditional advertisements:

1. Configure the IPv4 prefix list:

```
config router prefix-list
  edit "281"
    config rule
      edit 1
        set prefix 172.28.1.0 255.255.255.0
        unset ge
        unset le
      next
    end
  next
  edit "222"
    config rule
      edit 1
        set prefix 172.22.2.0 255.255.255.0
        unset ge
        unset le
      next
    end
  next
end
```

2. Configure the community list:

```
config router community-list
  edit "30:5"
```

```
        config rule
            edit 1
                set action permit
                set match "30:5"
            next
        end
    next
end
```

3. Configure the IPv4 route maps:

```
config router route-map
    edit "comm1"
        config rule
            edit 1
                set match-community "30:5"
                set set-route-tag 15
            next
        end
    next
    edit "2224"
        config rule
            edit 1
                set match-ip-address "222"
            next
        end
    next
    edit "2814"
        config rule
            edit 1
                set match-ip-address "281"
            next
        end
    next
end
```

4. Configure the IPv6 prefix list:

```
config router prefix-list6
    edit "adv-222"
        config rule
            edit 1
                set prefix6 2003:172:22:1::/64
                unset ge
                unset le
            next
        end
    next
    edit "list6-2"
        config rule
            edit 1
                set prefix6 2003:172:28:2::/64
                unset ge
                unset le
            next
        end
    next
end
```

```

    next
end

```

5. Configure the IPv6 route maps:

```

config router route-map
  edit "map-222"
    config rule
      edit 1
        set match-ip6-address "adv-222"
      next
    end
  next
  edit "map-282"
    config rule
      edit 1
        set action deny
        set match-ip6-address "list6-2"
      next
    end
  next
end

```

6. Configure the BGP settings:

```

config router bgp
  config neighbor
    edit "2.2.2.2"
      config conditional-advertise
        edit "2224"
          set condition-routemap "2814" "2224" "comm1"
          set condition-type non-exist
        next
      end
    next
  edit "2003::2:2:2:2"
    config conditional-advertise6
      edit "map-222"
        set condition-routemap "map-222" "map-282"
      next
    end
    set route-reflector-client6 enable
  next
end

```

To verify the IPv4 conditional advertisements:

```

# get router info bgp neighbors 2.2.2.2
...
Conditional advertise-map:
  Adv-map 2224root 2814root, cond-state 0-1
          2224root, cond-state 0-1
          comm1root, cond-state 0-0
...

```

In this output, the condition is that the routes in route maps 2814, 2224 and comm1 do not exist. However, routes for 2814 and 2224 exist, so the conditions are not met.

To verify the IPv6 conditional advertisements:

```
# get router info6 bgp neighbors 2003::2:2:2:2
...
Conditional advertise-map:
    Adv-map map-222root map-222root, cond-state 1-1
                                map-282root, cond-state 1-0
...
```

In this output, the condition is that the routes in route maps map-222 and map-282 exist. However, routes for map-222 exist, but map-282 does not, so the conditions are not met.

To view the conditional route maps:

```
# diagnose ip router command show-vrf root show running router bgp
...
neighbor 2.2.2.2 advertise-map 2224root exist-map 2814root
neighbor 2.2.2.2 advertise-map 2224root exist-map 2224root
neighbor 2.2.2.2 advertise-map 2224root exist-map comm1root
... ..
!
address-family ipv6
neighbor 2003::2:2:2:2 advertise-map map-222root non-exist-map map-222root
neighbor 2003::2:2:2:2 advertise-map map-222root non-exist-map map-282root
!
```

IPv6 example 1

In this example, the FortiGate advertises its local network to the secondary router when the primary router is down. The FortiGate detects the primary router is down in the absence of a learned route.

- When the FortiGate learns route 2003:172:28:1::/64 from the primary router, it does not advertise its local route (2003:172:22:1::/64) to the secondary router.
- When the FortiGate does not learn route 2003:17:28:1::/64 from the primary router, advertises its local route (2003:172:22:1::/64) to the secondary router.
- The BGP conditional advertisement condition is set to be true if the condition route map (2003:172:28:1::/64) is not matched (non-exist).

To configure BGP conditional advertisement with IPv6:**1. Configure the IPv6 prefix lists:**

```
config router prefix-list6
    edit "adv-222"
        config rule
            edit 1
```

```

        set prefix6 2003:172:22:1::/64
        unset ge
        unset le
    next
end
next
edit "lrn-281"
    config rule
        edit 1
            set prefix6 2003:172:28:1::/64
            unset ge
            unset le
        next
    end
next
end

```

2. Configure the route maps:

```

config router route-map
    edit "map-221"
        config rule
            edit 1
                set match-ip6-address "adv-222"
            next
        end
    next
    edit "map-281"
        config rule
            edit 1
                set match-ip6-address "lrn-281"
            next
        end
    next
end

```

3. Configure BGP:

```

config router bgp
    set as 65412
    set router-id 1.1.1.1
    set ibgp-multipath enable
    set network-import-check disable
    set graceful-restart enable
    config neighbor
        edit "2003::2:2:2:2"
            set soft-reconfiguration6 enable
            set remote-as 65412
            set update-source "loopback1"
            config conditional-advertise6
                edit "map-221"
                    set condition-routemap "map-281"
                    set condition-type non-exist
                next
            end
        next
    next
    edit "2003::3:3:3:3"

```

```

        set soft-reconfiguration6 enable
        set remote-as 65412
        set update-source "loopback1"
    next
end
end

```

In this configuration, if route map `map-281` does not exist, then the FortiGate advertises route map `map-221` to neighbor `2003::2:2:2`.

4. Verify the routing table:

```

# get router info6 routing-table bgp
B      2003:172:28:1::/64 [200/0] via 2003::3:3:3:3 (recursive via
****:***:***:***:***:****, port9), 01:23:45
B      2003:172:28:2::/64 [200/0] via 2003::3:3:3:3 (recursive via
****:***:***:***:***:****, port9), 23:09:22

```

When the FortiGate learns `2003:172:28:1::/64`, it will not advertise its local route `2003:172:22:1::/64` to neighbor `2003::2:2:2`. If the FortiGate has not learned `2003:172:28:1::/64`, it will advertise its local route `2003:172:22:1::/64` to neighbor `2003::2:2:2`.

IPv6 example 2

With the same IPv6 prefix lists and route maps, when the FortiGate does learn `2003:172:28:1::/64`, it advertises local route `2003:172:22:1::/64` to the secondary router. The BGP conditional advertisement condition is set to be true if the condition route map is matched (`exist`).

To configure BGP conditional advertisement with IPv6:

1. Configure BGP:

```

config router bgp
  config neighbor
    edit "2003::2:2:2"
      config conditional-advertise6
        edit "map-221"
          set condition-routemap "map-281"
          set condition-type exist
        next
      end
    next
  end
end

```

2. Verify the routing table:

```

# get router info6 routing-table bgp
B      2003:172:28:1::/64 [200/0] via 2003::3:3:3:3 (recursive via
****:***:***:***:***:****, port9), 01:23:45
B      2003:172:28:2::/64 [200/0] via 2003::3:3:3:3 (recursive via
****:***:***:***:***:****, port9), 23:09:22

```

When the FortiGate learns `2003:172:28:1::/64`, it will advertise its local route `2003:172:22:1::/64` to neighbor `2003::2:2:2`. If the FortiGate has not learned route `2003:172:28:1::/64`, it will not advertise its local route `2003:172:22:1::/64` to neighbor `2003::2:2:2`.

BGP conditional advertisements for IPv6 prefix when IPv4 prefix conditions are met and vice-versa

The FortiGate supports conditional advertisement of IPv4 and IPv6 route maps with `edit <advertise-routemap>` under `config conditional-advertise`, and supports configuring IPv4 and IPv6 route maps as conditions with the `condition-routemap` setting.

The FortiGate can cross-check conditions involving IPv4 and IPv6 route maps and perform conditional advertisements accordingly when those conditions are met. The global option, `cross-family-conditional-adv` in the BGP configuration settings allows this cross-checking to occur.

```
config router bgp
    set cross-family-conditional-adv {enable | disable}
    config conditional-advertise
        edit <advertise-routemap>
            set advertise-routemap <string>
            set condition-routemap <name1>, <name2>, ...
            set condition-type {exist | non-exist}
        next
    end
end
```

By default, the `cross-family-conditional-adv` setting is disabled. When disabled, the FortiGate will only check conditional route maps against the routing information base (RIB) of the IP address family (IPv4 or IPv6) that corresponds to the IP address family of the route map to be advertised conditionally.

For example, for an IPv6 conditional advertisement, if IPv4 conditional route maps have been configured, then the FortiGate will not meet any of these conditions because IPv4 routes will not exist in the IPv6 RIB. The same behavior applies for an IPv4 conditional advertisement, namely, that the FortiGate will not meet any configured IPv6 conditions since these routes will not exist in the IPv4 RIB. If routes do not match a conditional route map, then the condition is considered non-existent.

IPv4 and IPv6 BGP conditional advertisements using advertising and conditional route maps of the same IP address family are already supported in previous versions of FortiOS.

DS-Lite example

In this example, the FortiGate acts as a Dual-Stack Lite (DS-Lite) address family transition router (AFTR) where the customer equipment (CE) network via Router1 uses IPv6 and where Router2 is the internet gateway using IPv4.

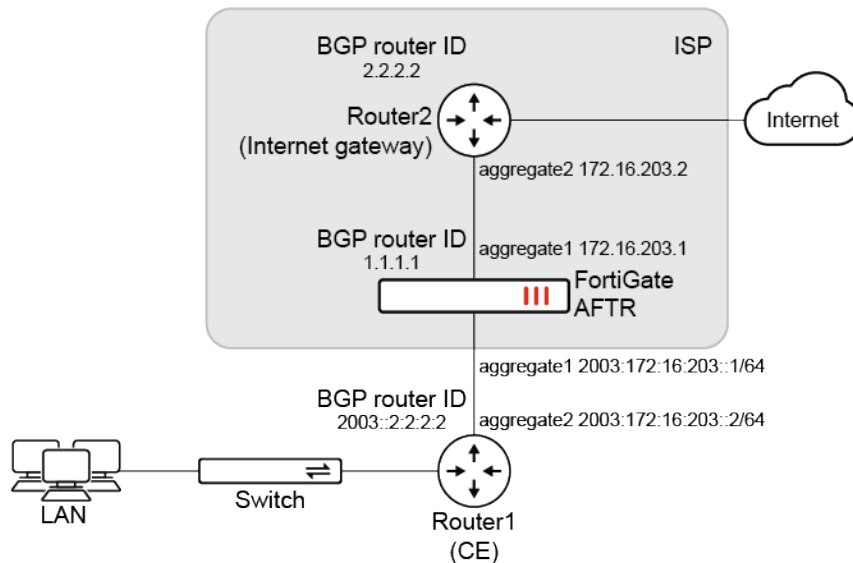

The administrator of the AFTR has the following requirements:

- The FortiGate needs to announce IPv4 pools for NAT translation towards the internet gateway only if the IPv6 B4 prefix exists in the routing table.
- The FortiGate needs to advertise the DS-Lite termination IPv6 address towards the CE network only if the IPv4 default route exists on the FortiGate.

The prefixes defined in IPv4 route map `2814` and IPv6 route map `map-281` both exist, so the FortiGate advertises the route map prefix in route-map `2224` (`172.22.2.0/255.255.255.0`) to its BGP neighbor `2.2.2.2`.

For IPv6 neighbor `2003::2:2:2:2`, the prefixes defined in IPv4 route map `2874` and IPv6 route map `map-38` both do not exist, and the `condition-type` is set to `non-exist`, so the FortiGate advertises the route map prefix in route map `map-222` (`2003:172:22:1::/64`) to its BGP neighbor `2003::2:2:2:2`.

When the global `cross-family-conditional-adv` is enabled, this is the only time the FortiGate will cross-check the address family; otherwise, it only checks the corresponding conditional map and treats the cross-family addresses as non-existent.

To configure the conditional advertisement to BGP neighbor 2.2.2.2 and its conditional route maps:

1. Configure the IPv4 prefix lists:

```
config router prefix-list
  edit "281"
    config rule
      edit 1
        set prefix 172.28.1.0 255.255.255.0
        unset ge
        unset le
      next
    end
  next
  edit "222"
    config rule
      edit 1
        set prefix 172.22.2.0 255.255.255.0
        unset ge
        unset le
      next
    end
  next
end
```

2. Configure the IPv6 prefix list:

```
config router prefix-list6
  edit "list6-1"
    config rule
      edit 1
        set prefix6 2003:172:28:1::/64
        unset ge
      next
    end
  next
end
```

```

        unset le
    next
end
next
end

```

3. Configure the route maps:

```

config router route-map
  edit "2814"
    config rule
      edit 1
        set match-ip-address "281"
      next
    end
  next
  edit "map-281"
    config rule
      edit 1
        set match-ip6-address "list6-1"
      next
    end
  next
  edit "2224"
    config rule
      edit 1
        set match-ip-address "222"
      next
    end
  next
end

```

To configure the conditional advertisement to BGP neighbor 2003::2.2.2.2 and its conditional route maps:

1. Configure the IPv4 prefix list:

```

config router prefix-list
  edit "287"
    config rule
      edit 1
        set prefix 172.28.7.0 255.255.255.0
        unset ge
        unset le
      next
    end
  next
end

```

2. Configure the IPv6 prefix lists:

```

config router prefix-list6
  edit "list6-38"
    config rule
      edit 1
        set prefix6 2003:172:38:1::/64
        unset ge

```

```

        unset le
    next
end
next
edit "adv-222"
    config rule
        edit 1
            set prefix6 2003:172:22:1::/64
            unset ge
            unset le
        next
    end
next
end

```

3. Configure the route maps:

```

config router route-map
    edit "2874"
        config rule
            edit 1
                set match-ip-address "287"
            next
        end
    next
    edit "map-38"
        config rule
            edit 1
                set match-ip6-address "list6-38"
            next
        end
    next
    edit "map-222"
        config rule
            edit 1
                set match-ip6-address "adv-222"
            next
        end
    next
end

```

To configure the BGP settings with address family cross-checking:

```

config router bgp
    set as 65412
    set router-id 1.1.1.1
    set ibgp-multipath enable
    set network-import-check disable
    set cluster-id 1.1.1.1
    set graceful-restart enable

B      172.29.1.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:37:30,
[1/0]
B      172.29.2.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:37:30,
[1/0]
```

To verify the BGP routing table for IPv6 and confirm the conditional advertisement occurred:

```
# get router info6 routing-table bgp
Routing table for VRF=0
B      2003:172:22:1::/64 [200/0] via 2003::1:1:1:1 (recursive via 2003:172:16:203::1,
agg2), 00:00:01, [1024/0]
B      2003:172:28:1::/64 [200/0] via 2003::3:3:3:3 (recursive via fe80::a5b:eff:feeb:ca45,
port1), 00:37:59, [1024/0]
B      2003:172:28:2::/64 [200/0] via 2003::3:3:3:3 (recursive via fe80::a5b:eff:feeb:ca45,
port1), 00:37:59, [1024/0]
```

Behavior when address family cross-checking is disabled

Using a similar BGP configuration with `cross-family-conditional-adv` disabled, note the following behavior based on the condition type.

When the condition type is set to exist:

```
config router bgp
  set cross-family-conditional-adv disable
  config neighbor
    edit "2.2.2.2"
      config conditional-advertise
        edit "222v4"
          set condition-routemap "4-281" "6-281"
          set condition-type exist
        next
      end
    next
  end
end
```

The FortiGate will only check the IPv4 RIB table to see if there is a matching IP address for each route map. Any IPv6 address under the route map will not get checked in the corresponding IPv6 RIB table, and the condition result will be non-existent. The 222v4 route map will not advertise to its neighbor because the result is non-existent, while the condition type is existent.

When the condition type is set to non-exist:

```
config router bgp
    set cross-family-conditional-adv disable
    config neighbor
        edit "2003::2:2:2:2"
            config conditional-advertise6
                edit "v6-222"
                    set condition-routemap "v6-238" "v4-287"
                    set condition-type non-exist
                next
            end
        next
    end
end
```

If the v6-238 IPv6 prefix does not exist in the IPv6 RIB table, then the FortiGate will only check v4-287 in the IPv6 RIB table. The FortiGate will not find it because it is an IPv4 address. Since the condition type is also non-exist, route v6-222 will be advertised to its neighbor.

BGP error handling per RFC 7606

The FortiGate uses one of the three approaches to handle malformed attributes in BGP UPDATE messages, in order of decreasing severity:

1. Notification and Session reset
2. Treat-as-withdraw
3. Attribute discard

When a BGP UPDATE message contains multiple malformed attributes, the most severe approach that is triggered by one of the attributes is followed. See [RFC 7606](#) for more information.

The following table lists the BGP attributes, and how FortiGate handles a malformed attribute in the UPDATE message:

BGP attribute	Handling
origin	Handled by the treat-as-withdraw approach.
AS path	Handled by the treat-as-withdraw approach.
AS 4 path	Handled by the attribute discard approach.
aggregator	Handled by the attribute discard approach.
aggregator 4	Handled by the attribute discard approach.
next-hop	Handled by the treat-as-withdraw approach.
multiple exit discriminator	Handled by the treat-as-withdraw approach.

BGP attribute	Handling
local preference	Handled by the treat-as-withdraw approach.
atomic aggregate	Handled by the attribute discard approach.
community	Handled by the treat-as-withdraw approach.
extended community	Handled by the treat-as-withdraw approach.
originator	Handled by the treat-as-withdraw approach.
cluster	Handled by the treat-as-withdraw approach.
PMSI	Handled by the treat-as-withdraw approach.
MP reach	Handled by the notification message approach.
MP unreachable	Handled by the notification message approach.
attribute set	Handled by the treat-as-withdraw approach.
AIGP	Handled by the treat-as-withdraw approach.
Unknown	If the BGP flag does not indicate that this is an optional attribute, this malformed attribute is handled by the notification message approach.

This example shows how the ORIGIN attribute can be malformed, and how it is handled.

Reason for malformed attribute	Handling
ORIGIN attribute length not one	The prefix will be gone and the BGP session will not be reset.
ORIGIN attribute value is invalid	The prefix will be gone and the BGP session will not be reset.
Two ORIGIN attributes with different values	The attributes are ignored, the BGP session will not be reset, and the BGP route will remain.
ORIGIN attribute is absent	The BGP session will be reset

For example, if the FortiGate receives a malformed UPDATE packet from the neighbor at 27.1.1.124 that has no ORIGIN attribute, the BGP session is reset and the state of the neighbor is shown as `Idle`, the first state of the BGP neighborhood connection.

```
# get router info bgp summary
VRF 0 BGP router identifier 27.1.1.125, local AS number 125
BGP table version is 6
1 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
3.3.3.3	4	33	33	0	0	0	0	0	never Active
27.1.1.124	4	124	94	126	0	0	0	0	never Idle

Total number of neighbors 2

BGP next hop tag-match mode

Tag-match mode can be configured to increase flexibility when controlling how BGP routes' next hops are resolved:

```
config router bgp
    set tag-resolve-mode {disable | preferred | merge}
end
```

Best-match (disable)	Resolve the BGP route's next hops with best-matched routes. This is the default setting.
Tag-match (preferred)	Resolve the BGP route's next hops with routes that have the same tag. If there are no results, resolve the next hops with best-matched routes.
Tag-and-best-match (merge)	Merge tag-match with best-match if they are using different routes, then let shortcuts hide their parents. The results exclude the next hops of tag-match whose interfaces have appeared in best-match.

In these examples:

- Each spoke has two IPsec tunnels to each hub, and one BGP peer on loopback interface to each hub (route-reflector).
- The loopbacks are exchanged with IKE between the spokes and hubs. They are installed as static routes that are used to provide reachability for establishing BGP neighbors.
- The summary BGP routes from the loopback IP address ranges that originated on the hubs are advertised to the spokes for resolving the BGP next hops on the spokes.
- The spokes' PC LAN subnets are reflected by the hubs.
- Spoke_1 receives BGP routes (the LAN subnet and loopback IP summary) from Hub_1 with tag 1 and from Hub_2 with tag 2.
- SD-WAN is enabled on Spoke_1, and all of the tunnels are SD-WAN members.

Example 1: Connection between Hub and Spoke down

If the connections between Hub_1 and Spoke_2 are down, traffic from PC_3 to PC_4 can still go through Hub_1 because of the best-match resolving on Spoke_1, but packets will be dropped on Hub_1. When tag-match is enabled on Spoke_1, the spoke will resolve the PC_4 LAN route to Hub2, and traffic will be forwarded to Hub_2 and reach its destination.

To test the tag-match mode:

1. View the key routes on Spoke_1:

```
Spoke_1(root) # get router info routing-table all
C      10.0.3.0/24 is directly connected, port4
B      10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11 tunnel
172.31.1.1), 20:09:52
        (recursive via H1_T22 tunnel 10.0.0.2), 20:09:52
        (recursive via H2_T11 tunnel 172.31.1.101), 20:09:52
        (recursive via H2_T22 tunnel 10.0.0.4), 20:09:52
B      172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
23:25:37
        (recursive via H1_T22 tunnel 10.0.0.2), 23:25:37
        [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 23:25:37
        (recursive via H2_T22 tunnel 10.0.0.4), 23:25:37
S      172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
        [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S      172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
        [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C      172.31.0.65/32 is directly connected, Loopback0
...
```

172.31.0.0/25 is the loopback IP summary originated by both Hub_1 and Hub_2. The next hop of the PC_4 LAN route is resolved to Hub_1 (H1_T11, H1_T22) and Hub_2 (H2_T11, H2_T22) based on the loopback IP summary route.

2. When connections between Spoke_2 and Hub_1 fails due to the BGP neighbor, tunnels, or physical ports going down, the PC_4 LAN route can be still resolved to Hub_1 and Hub_2 because the loopback IP summary can still be received from both Hub_1 and Hub_2:

```
Spoke_1(root) # get router info routing-table all
C      10.0.3.0/24 is directly connected, port4
B      10.0.4.0/24 [200/0] via 172.31.0.66 (recursive via H1_T11 tunnel 172.31.1.1),
00:03:06
        (recursive via H1_T22 tunnel 10.0.0.2), 00:03:06
        (recursive via H2_T11 tunnel 172.31.1.101), 00:03:06
        (recursive via H2_T22 tunnel 10.0.0.4), 00:03:06
B      172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
23:55:34
        (recursive via H1_T22 tunnel 10.0.0.2), 23:55:34
        [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 23:55:34
        (recursive via H2_T22 tunnel 10.0.0.4), 23:55:34
...
```

3. If traffic sent from PC_3 to PC_4 goes through Hub_1, packets are dropped because there is no PC_4 LAN route on Hub_1:

```
Spoke_1 (root) # diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
```

```

filters=[host 10.0.4.2]
11.261264 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
11.261349 H1_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request
12.260268 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
12.260291 H1_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request

```

```

Hub_1 (root) # diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
filters=[host 10.0.4.2]
6.966064 EDGE_T1 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.965012 EDGE_T1 in 10.0.3.2 -> 10.0.4.2: icmp: echo request

```

4. If the tag-match mode is set to tag-match (preferred) on Spoke_1, then the PC_4 LAN route can only be resolved to Hub_2 because of tag-match checking:

```

Spoke_1(root) # get router info routing-table all
C      10.0.3.0/24 is directly connected, port4
B      10.0.4.0/24 [200/0] via 172.31.0.66 tag 2 (recursive via H2_T11 tunnel
172.31.1.101), 00:02:35
          (recursive via H2_T22 tunnel 10.0.0.4), 00:02:35
B      172.31.0.0/25 [200/0] via 172.31.0.1 tag 1 (recursive via H1_T11 tunnel
172.31.1.1), 03:18:41
          (recursive via H1_T22 tunnel 10.0.0.2), 03:18:41
          [200/0] via 172.31.0.2 tag 2 (recursive via H2_T11 tunnel 172.31.1.101),
03:18:41
          (recursive via H2_T22 tunnel 10.0.0.4), 03:18:41
...
Spoke_1 (root) # get router info routing-table details 10.0.4.0/24

Routing table for VRF=0
Routing entry for 10.0.4.0/24
  Known via "bgp", distance 200, metric 0, best
  Last update 00:01:11 ago
  * 172.31.0.66, tag 2 (recursive via H2_T11 tunnel 172.31.1.101), tag-match
    (recursive via H2_T22 tunnel 10.0.0.4), tag-match

```

5. If traffic is again sent from PC_3 to PC_4, it will go through Hub_2 and reach the destination:

```

Spoke_1 (root) # diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
filters=[host 10.0.4.2]
7.216948 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.217035 H2_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.217682 H2_T11 in 10.0.4.2 -> 10.0.3.2: icmp: echo reply
7.217729 port4 out 10.0.4.2 -> 10.0.3.2: icmp: echo reply

```

Example 2: SD-WAN failover when shortcut down

After the shortcut from Spoke_1 to Spoke_2 is established, Spoke_1 will only resolve the PC_4 LAN route to the shortcut, because of best-match resolving, prohibiting SD-WAN failover. When tag-and-best-match is enabled on Spoke_1, the spoke can resolve the PC_4 LAN route to the shortcut and to other alternative tunnels, allowing SD-WAN failover.

To test the tag-and-best-match mode:

1. Unset `tag-resolve-mode` and resume the connections between Spoke_2 and Hub_1. The routing table on Spoke_1 changes to the initial state:

```
Spoke_1(root) # get router info routing-table all
C      10.0.3.0/24 is directly connected, port4
B      10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11 tunnel
172.31.1.1), 00:01:54
        (recursive via H1_T22 tunnel 10.0.0.2), 00:01:54
        (recursive via H2_T11 tunnel 172.31.1.101), 00:01:54
        (recursive via H2_T22 tunnel 10.0.0.4), 00:01:54
B      172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
03:30:35
        (recursive via H1_T22 tunnel 10.0.0.2), 03:30:35
        [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 03:30:35
        (recursive via H2_T22 tunnel 10.0.0.4), 03:30:35
S      172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
        [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S      172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
        [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C      172.31.0.65/32 is directly connected, Loopback0
...

```

2. Send traffic from PC_3 to PC_4.

The shortcut from Spoke_1 to Spoke_2 is established.

The PC_4 LAN route is only resolved to the shortcut because of best-match resolving. If the shortcut is out of SLA, then the traffic cannot switch over to another, alternative tunnel.

```
Spoke_1 (root) # get router info routing-table all
C      10.0.3.0/24 is directly connected, port4
B      10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11_0 tunnel
10.0.0.40), 00:09:22
B      172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
03:40:12
        (recursive via H1_T22 tunnel 10.0.0.2), 03:40:12
        [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 03:40:12
        (recursive via H2_T22 tunnel 10.0.0.4), 03:40:12
S      172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
        [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S      172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
        [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C      172.31.0.65/32 is directly connected, Loopback0
S      172.31.0.66/32 [15/0] via H1_T11_0 tunnel 10.0.0.40, [1/0]
...

```

3. If the tag-match mode is set to tag-and-best-match (merge) on Spoke_1, then the PC_4 LAN route is resolved to the H1_T11_0 shortcut based on best-match resolving, and to H1_T11, H1_T22, H2_T11, H2_T22 based on tag-match resolving. It is then resolved to H1_T11, H1_T22, H2_T11, H2_T22 after letting the shortcut hide its parent tunnel.

```
Spoke_1 (root) # get router info routing-table all
C      10.0.3.0/24 is directly connected, port4
B      10.0.4.0/24 [200/0] via 172.31.0.66 tag 1 (recursive via H1_T11_0 tunnel
10.0.0.40), 00:07:36

```

```

        (recursive via H1_T22 tunnel 10.0.0.2), 00:07:36
    [200/0] via 172.31.0.66 tag 2 (recursive via H1_T11_0 tunnel 10.0.0.40),
00:07:36
        (recursive via H2_T11 tunnel 172.31.1.101), 00:07:36
        (recursive via H2_T22 tunnel 10.0.0.4), 00:07:36
B      172.31.0.0/25 [200/0] via 172.31.0.1 tag 1 (recursive via H1_T11 tunnel
172.31.1.1), 03:48:26
        (recursive via H1_T22 tunnel 10.0.0.2), 03:48:26
    [200/0] via 172.31.0.2 tag 2 (recursive via H2_T11 tunnel 172.31.1.101),
03:48:26
        (recursive via H2_T22 tunnel 10.0.0.4), 03:48:26
S      172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
        [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S      172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
        [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C      172.31.0.65/32 is directly connected, Loopback0
S      172.31.0.66/32 [15/0] via H1_T11_0 tunnel 10.0.0.40, [1/0]

...

Spoke_1 (root) # get router info routing-table details 10.0.4.0/24

Routing table for VRF=0
Routing entry for 10.0.4.0/24
  Known via "bgp", distance 200, metric 0, best

```

BGP neighbor password

A BGP neighbor password is used for the neighbor range. Once a BGP group is configured, it uses a password to establish the neighborhood.

```

config router bgp
  config neighbor-group
    edit <name>
      set password <password>
    next

```

To configure the BGP group:

1. Configure the R3 FortiGate settings:

```

config router bgp
  config neighbor-group
    edit "FGT"
      set soft-reconfiguration enable
      set remote-as 65050
      set local-as 65518
      set local-as-no-prepend enable
      set local-as-replace-as enable
      set route-map-in "del-comm"
      set keep-alive-timer 30
      set holdtime-timer 90
      set update-source "np0_vlink0"
      set weight 1000
      set password ENC *****
    next
  end
  config neighbor-range
    edit 1
      set prefix 172.16.201.0 255.255.255.0
      set max-neighbor-num 10
      set neighbor-group "FGT"
    next
  end
end
end

```

2. Configure the R4 router settings:

```

config router bgp
  config neighbor
    edit "172.16.201.1"
      set soft-reconfiguration enable
      set remote-as 65518
      set password *****
    next
  end
end
end

```

Defining a preferred source IP for local-out egress interfaces on BGP routes

The preferred source IP can be configured on BGP routes so that local-out traffic is sourced from that IP. In the following example, a route map is configured to set the preferred source IP so that the BGP route can support the preferred

source.

To configure preferred source IPs for BGP routing:

1. Configure the route maps:

```

config router route-map
  edit "map1"
    config rule
      edit 1
        set set-ip-prefsrc 1.1.1.1
      next
    end
  next
  edit "map2"
    config rule
      edit 1
        set set-ip-prefsrc 1.1.1.2
      next
    end
  next
end

```

2. Configure the BGP settings:

```

config router bgp
  set as 65412
  set router-id 1.1.1.1
  set ibgp-multipath enable
  set cluster-id 1.1.1.1
  set graceful-restart enable
  config aggregate-address
    edit 1
      set prefix 172.28.0.0 255.255.0.0
      set as-set enable
      set summary-only enable
    next
  end
  config neighbor
    edit "3.3.3.3"
      set capability-graceful-restart enable
      set soft-reconfiguration enable
      set prefix-list-out "local-out"
      set remote-as 65412
      set route-map-in "map2"
      set route-map-out "as-prepend"
      set keep-alive-timer 30
      set holdtime-timer 90
    next
  end
end

```

```

        set update-source "loopback1"
        set route-reflector-client enable
    next
    edit "2.2.2.2"
        set advertisement-interval 5
        set activate6 disable
        set capability-graceful-restart enable
        set soft-reconfiguration enable
        set distribute-list-out "local-out-FGTB-deny"
        set remote-as 65412
        set route-map-in "map1"
        set route-map-out "as-rewrite"
        set keep-alive-timer 30
        set holdtime-timer 90
        set update-source "loopback1"
    next
end
end

```

To verify the configuration:

1. Verify the BGP routing table for 172.25.1.0/24:

```

# get router info bgp network 172.25.1.0/24
VRF 0 BGP routing table entry for 172.25.1.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
    Not advertised to any peer
    Original VRF 0
    Local
        2.2.2.2 (metric 10050) from 2.2.2.2 (2.2.2.2)
            Origin IGP metric 0, localpref 100, valid, internal, best, prefsrc 1.1.1.1
            Last update: Wed Jan 25 15:15:48 2023

```

2. Verify the BGP routing table for 172.28.5.0/24:

```

# get router info bgp network 172.28.5.0/24
VRF 0 BGP routing table entry for 172.28.5.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table, Advertisements suppressed
by an aggregate.)
    Not advertised to any peer
    Original VRF 0
    65050, (Received from a RR-client)
        3.3.3.3 (metric 11000) from 3.3.3.3 (3.3.3.3)
            Origin IGP metric 0, localpref 100, valid, internal, best, prefsrc 1.1.1.2
            Last update: Wed Jan 25 15:15:48 2023

```

3. Verify the kernel routing table for 172.28.5.0/24:

```

# get router info kernel | grep -B 2 172.28.5.0/24
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.28.1.0/24
pref=1.1.1.2 gwy=172.16.200.4 dev=9(port1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.28.2.0/24
pref=1.1.1.2 gwy=172.16.200.4 dev=9(port1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.28.5.0/24
pref=1.1.1.2 gwy=172.16.200.4 dev=9(port1)

```

4. Verify the kernel routing table for 172.25.1.0/24:

```
# get router info kernel | grep -A 2 172.25.1.0/24
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.25.1.0/24
pref=1.1.1.1 gwy=172.16.203.2 dev=33 (agg1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.26.1.0/24
pref=1.1.1.1 gwy=172.16.203.2 dev=33 (agg1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.26.2.0/24
pref=1.1.1.1 gwy=172.16.203.2 dev=33 (agg1)
```

The FortiGate learns routes from router 3.3.3.3 and prefers the source IP of 1.1.1.2. It learns routes from router 2.2.2.2 and prefers source IP of 1.1.1.1.

5. Run a sniffer trace after some traffic passes.

a. When trying to reach a destination in the 172.25.1.0/0 subnet through router 2.2.2.2:

```
# diagnose sniffer packet any "icmp" 4
interfaces=[any]
filters=[icmp]
9.244334 agg1 out 1.1.1.1 -> 172.25.1.2: icmp: echo request
9.244337 port12 out 1.1.1.1 -> 172.25.1.2: icmp: echo request
10.244355 agg1 out 1.1.1.1 -> 172.25.1.2: icmp: echo request
10.244357 port12 out 1.1.1.1 -> 172.25.1.2: icmp: echo request
```

b. When trying to reach a destination in the 172.28.5.0/24 subnet through router 3.3.3.3:

```
# diagnose sniffer packet any "icmp" 4
interfaces=[any]
filters=[icmp]
2.434035 port1 out 1.1.1.2 -> 172.28.5.2: icmp: echo request
3.434059 port1 out 1.1.1.2 -> 172.28.5.2: icmp: echo request
```

Traffic destined for the 172.25.1.0/24 subnet uses 1.1.1.1 as source. Traffic destined for the 172.28.5.0/24 subnet uses 1.1.1.2 as source.

BGP multi-exit discriminator

Border Gateway Protocol (BGP) is the routing protocol that governs how internet traffic is efficiently routed between autonomous systems (AS). BGP uses path attributes for its best path calculation to a network.

Multi-Exit Discriminator (MED) is a BGP path attribute that discriminates among multiple exit or entry points to the same neighboring AS. MED is also known as Optional Non-Transitive path attribute. The lower the MED value, the more preferred the path is to the receiving router.

MED is typically utilized when an AS has multiple exit points to another AS. In such cases, the AS may want to influence incoming traffic by advertising different MED values for the same route.

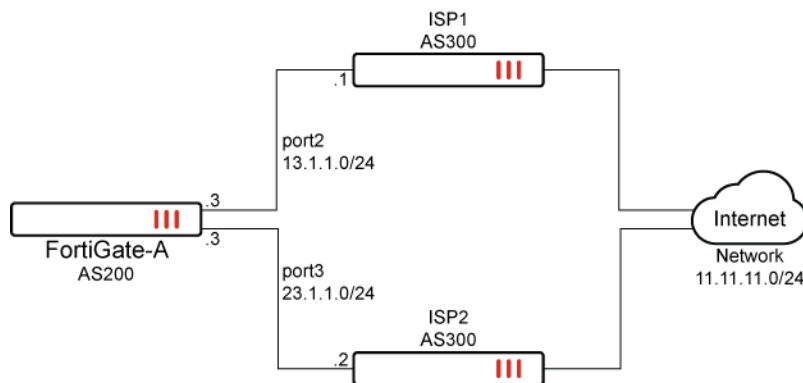

Common use case

A common use case for MED is in the context of a dual-homed AS. In a dual-homed AS scenario, the FortiGate connects to two different ISPs belonging to the same AS for redundancy and load balancing. By manipulating the MED value, the AS can direct traffic to one ISP over the other. For instance, if one link is congested, the AS can advertise a higher MED value for that link, making the other link more suitable to incoming traffic.

MED is a BGP path attribute that discriminates among multiple exit or entry points to the same neighboring AS. If an administrator has two or more eBGP peering to different AS then the local preference can be used to influence the routing decision.

The following example discusses the use of MED in dual-homed AS network and the configuration of MED Path Attribute on FortiOS.

Characteristics of the topology include the following:

- FortiGate-A has two internet service providers: ISP1 and ISP2.
- FortiGate-A belongs to AS 200.
- ISP1 and ISP2 both belong to AS 300.
- FortiGate-A will establish eBGP peering relationships with ISP1 and ISP2.
- Network 11.11.11.0/24 resides on the Internet and is reachable by both ISP1 and ISP2.
- eBGP multipath is enabled on FortiGate-A if FortiGate-A needs to perform equal cost load-balancing of traffic between both ISP1 and ISP2 to reach to 11.11.11.0/24.
- The network 11.11.11.0/24 on the Internet is being advertised by both ISP1 and ISP2 to FortiGate-A through eBGP.

For this example, the traffic originating from behind the FortiGate-A should prefer ISP1 rather than ISP2 to reach 11.11.11.0/24, and needs to use the BGP MED Path Attribute. This is done by configuring `set set-metric` in a route map configuration and ensuring the MED value of ISP1 is less than that of ISP2.

To configure MED in a dual-homed AS network using the CLI:

1. Configure eBGP peering on FortiGate-A by specifying the BGP neighbors:

```

config router bgp
    set as 200
    set router-id 2.2.2.2
    config neighbor
        edit "13.1.1.1"
            set remote-as 300
        next
        edit "23.1.1.2"
            set remote-as 300
        next
    end
end

```

2. Configure eBGP on ISP1 and ISP2, and advertise the 11.11.11.0/24 network:

```

config router bgp
    set as 300
    set router-id 3.3.3.3
    config neighbor
        edit "13.1.1.3"

```

```

        set remote-as 200
    next
end
config network
    edit 1
        set prefix 11.11.11.0 255.255.255.0
    next
end
end

```

3. Verify the eBGP neighbors on Fortigate-A with ISP1 and ISP2:

```

# get router info bgp summary
VRF 0 BGP router identifier 2.2.2.2, local AS number 200
BGP table version is 6
1 BGP AS-PATH entries
0 BGP community entries

```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
13.1.1.1	4	300	48	50	0	0	0	00:25:45	1
23.1.1.2	4	300	56	60	6	0	0	00:26:30	1

4. Configure the prefix list to filter and select the 11.11.11.0/24 subnet inside the prefix list:

a. Configure ISP1:

```

config router prefix-list
    edit "ISP1_Prefix_List"
        config rule
            edit 1
                set prefix 11.11.11.0 255.255.255.0
            next
        end
    next
end

```

b. Configure ISP2:

```

config router prefix-list
    edit "ISP2_Prefix_List"
        config rule
            edit 1
                set prefix 11.11.11.0 255.255.255.0
            next
        end
    next
end

```

5. Configure route maps and configure the MED value:

a. Configure ISP1:

```

config router route-map
    edit "MED_Route_MAP"
        config rule
            edit 1
                set match-ip-address "ISP1_Prefix_List"
                set set-metric 300
            next
        end
    end

```

```

    next
end

```

b. Configure ISP2:

```

config router route-map
    edit "MED_Route_MAP_2"
        config rule
            edit 1
                set match-ip-address "ISP2_Prefix_List"
                set set-metric 400
            next
        end
    next
end

```

6. Apply the route map in the outbound direction:

Applying the configuration in the outbound direction ensures that the MED is changed to the respective value for the route 11.11.11.0/24 specified in the prefix list.

a. Configure the ISP1 BGP:

```

config router bgp
    set as 300
    set router-id 3.3.3.3
    config neighbor
        edit "13.1.1.3"
            set remote-as 200
            set route-map-out "MED_Route_MAP"
        next
    end
end

```

b. Configure the ISP2 BGP:

```

config router bgp
    set as 300
    set router-id 4.4.4.4
    config neighbor
        edit "23.1.1.3"
            set remote-as 200
            set route-map-out "MED_Route_MAP_2"
        next
    end
end

```

7. Verify that ISP1 is selected as the best path to reach the 11.11.11.0/24 network:

The neighbor that is considered the best, valid route is marked with a *>.

```

# get router info bgp network
VRF 0 BGP table version is 6, local router ID is 2.2.2.2

```

Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete

Network	Next Hop	Metric	LocPrf	Weight	RouteTag	Path
*> 11.11.11.0/24	13.1.1.1	300		0	0	300 i <- /1>
*	23.1.1.2	400		0	0	300 i <- /->

Total number of prefixes 1

8. Verify the routing table of FortiGate-A:

The routing table only contains the best and valid paths.

```
# get router info routing-table details
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
```

```
Routing table for VRF=0
B      11.11.11.0/24 [20/300] via 13.1.1.1, port2, 00:37:47
C      13.1.1.0/24 is directly connected, port2
C      23.1.1.0/24 is directly connected, port3
```

Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically, the problems with a BGP network that has been configured involve routes going offline frequently. This is called route flap and causes problems for the routers using that route.

Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the following CLI command:

```
# execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the following CLI command:

```
# execute router clear bgp as 650001
```

Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term that is used if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables. This creates a lot of administration traffic on the network and the same traffic re-occurs when that router comes back online. If the problem is something like a faulty network cable that alternates online and offline every 10 seconds, there could easily be an overwhelming amount of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate devices in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline, resulting in route flap. While this doesn't occur often, or more than once at a time, it can still result in an interruption in traffic which is disruptive for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they don't expire during the failover process. Also, configuring graceful restart on the HA cluster helps with a smooth failover.

The first method of dealing with route flap is to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either avoid using that interface or swap in a functioning router. If the power source is bad on a router, either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However, if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- [Holdtime timer on page 513](#)
- [Dampening on page 514](#)
- [Graceful restart on page 514](#)
- [BFD on page 516](#)

Holdtime timer

The first step to troubleshooting a flapping route is the holdtime timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the holdtime timer won't allow the FortiGate to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate. For the duration of the other outages, there won't be changes because the Fortigate is essentially treating this router as down. If the route is still flapping after the timer expires, it will start again.

If the route isn't flapping (for example, if it goes down, comes up, and stays back up) the timer will still count down and the route is ignored for the duration of the timer. In this situation, the route is seen as down longer than it really is but there will be only the one set of route updates. This isn't a problem in normal operation because updates are not frequent.

The potential for a route to be treated as down when it's really up can be viewed as a robustness feature. Typically, you don't want most of your traffic being routed over an unreliable route. So if there's route flap going on, it's best to avoid that route if you can. This is enforced by the holdtime timer.

How to configure the holdtime timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the holdtime timer.

For example, your network has two routes that you want to set the timer for. One is your main route (to 10.12.101.4) that all of your Internet traffic goes through, and it can't be down for long if it's down. The second is a low speed connection to a custom network that's used infrequently (to 10.13.101.4). The timer for the main route should be fairly short (for example, 60 seconds). The second route timer can be left at the default, since it's rarely used.

To configure the BGP holdtime timer:

```

config router bgp
  config neighbor
    edit 10.12.101.4
      set holdtime-timer 60
      set keepalive-timer 60
    next
    edit 10.13.101.4
      set holdtime-timer 180
      set keepalive-timer 60
    next
  end
end

```

Dampening

Dampening is a method that's used to limit the amount of network problems due to flapping routes. With dampening, the flapping still occurs but the peer routers pay less and less attention to that route as it flaps more often. One flap doesn't start dampening, but the second flap starts a timer where the router won't use that route because it is considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There's a period of time called the reachability half-life, after which a route flap will be suppressed for only half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate device's cache by using one of the `execute router clear bgp` CLI commands:

```
# execute router clear bgp dampening {<ip_address> | <ip_address/netmask>}
```

or

```
# execute router clear bgp flap-statistics {<ip_address> | <ip_address/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the following CLI command:

```
# execute router clear bgp dampening 10.10.0.0/16
```

To configure BGP route dampening:

```

config router bgp
  set dampening {enable | disable}
  set dampening-max-suppress-time <minutes_integer>
  set dampening-reachability-half-life <minutes_integer>
  set dampening-reuse <reuse_integer>
  set dampening-route-map <routemap-name_str>
  set dampening-suppress <limit_integer>
  set dampening-unreachability-half-life <minutes_integer>
end

```

Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded but the hardware can still function normally.

Graceful restart is best used for these situations where routing won't be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart doesn't have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster advertises that it is going offline, and will not appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table. If there is a flap, the HA cluster routing table will be out-of-date.

For example, the FortiGate is one of four BGP routers that send updates to each other. Any of those routers may support graceful starting. When a router plans to go offline, it sends a message to its neighbors stating how long it expects to be offline. This way, its neighboring routers don't remove it from their routing tables. However, if that router isn't back online when expected, the routers will mark it offline. This prevents routing flap and its associated problems.

FortiGate devices support both graceful restart of their own BGP routing software and neighboring BGP routers.

Currently, FortiGates do not support BGP graceful restart when peering with neighbor routers operating in graceful restart helper-only mode.

To configure BGP graceful restart:

```
config router bgp
    set graceful-restart {disable | enable}
    set graceful-restart-time <seconds_integer>
    set graceful-stalepath-time <seconds_integer>
    set graceful-update-delay <seconds_integer>
    config neighbor
        edit 10.12.101.4
            set capability-graceful-restart {enable | disable}
        next
    end
end
```

Before the restart, the router sends its peers a message to say it's restarting. The peers mark all the restarting router's routes as stale, but they continue to use the routes. The peers assume the router will restart, check its routes, and take care of them, if needed, after the restart is complete. The peers also know what services the restarting router can maintain during its restart. After the router completes the restart, the router sends its peers a message to say it's done restarting.

To restart the router:

```
# execute router restart
```

Scheduled time offline

Graceful restart is a means for a router to advertise that it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their routing table until after a set time elapses. During that time, if the router comes back online, everything continues to function as normal. If that

router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that the router will be offline for a long time.

The following example demonstrates if you want to configure graceful restart on the FortiGate where you expect the FortiGate to be offline for no more than two minutes, and after three minutes the BGP network should consider the FortiGate to be offline.

To configure graceful restart time settings:

```
config router bgp
    set graceful-restart enable
    set graceful-restart-time 120
    set graceful-stalepath-time 180
end
```

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD communicate with each other and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

For more information about BFD, see [BFD on page 516](#).

BGP path selection process

Sometimes the FortiGate may receive multiple BGP paths from neighbors and must decide which is the best path to take. The following criteria are used to determine the best path.

Consider only routes with no AS loops and a valid next hop, and then:

1. Prefer the highest weight (this attribute is local to the FortiGate).
2. Prefer the highest local preference (applicable within AS).
3. Prefer the route originated by the local router (next hop = 0.0.0.0).
4. Prefer the shortest AS path.
5. Prefer the lowest origin code (IGP > EGP > incomplete).
6. Prefer the lowest MED (exchanged between autonomous systems).
7. Prefer the EBGp path over IBGP path.
8. Prefer the path through the closest IGP neighbor.
9. Prefer the oldest route for EBGp paths.
10. Prefer the path with the lowest neighbor BGP router ID.
11. Prefer the path with the lowest neighbor IP address.

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-enabled router fail to arrive, that router is declared to be down. BFD communicates this information to the associated routing protocols and the routing information is updated. It helps detect one way device failure and is used for fast convergence of routing protocols.

BFD can run on an entire FortiGate, selected interfaces, or on a protocol, such as BGP, for all configured interfaces. The configuration hierarchy allows each lower level to override the BFD setting of the upper level. For example, if you enable BFD for an entire FortiGate, you can disable BFD for an interface or for BGP.

Echo mode and authentication are not supported for BFD on the FortiGate.

BFD can be enabled per device, VDOM, or interface. Once enabled, a BFD neighbor should be defined. Finally, enable BFD on a route or routing protocol.

To configure BFD for an entire FortiGate:

```
config system settings
    set bfd {enable | disable}
    set bfd-desired-min-tx <ms>
    set bfd-required-min-rx <ms>
    set bfd-detect-mult <multiplier>
    set bfd-dont-enforce-src-port {enable | disable}
end
```

To configure BFD for an interface:

```
config system interface
    edit <interface-name>
        set bfd {global | enable | disable}
        set bfd-desired-min-tx <ms>
        set bfd-required-min-rx <ms>
        set bfd-detect-mult <multiplier>
    next
end
```

To configure BFD neighbors:

```
config router {bfd | bfd6}
    config neighbor
        edit <IP-address>
            set interface <interface-name>
        next
    end
end
```

To show BFD neighbors:

```
# get router {info | info6} bfd neighbor
```

To show BFD requests:

```
# get router {info | info6} bfd requests
```

BFD and static routes

BFD for static routes allows you to configure routing failover based on remote path failure detection. BFD removes a static route from the routing table if the FortiGate can't reach the route's destination and returns the route to the routing table if the route's destination is restored.

For example, you can add two static routes with BFD enabled. If one of the routes has a higher priority, all matching traffic uses that route. If BFD determines that the link to the gateway of the route with the higher priority is down, the higher priority route is removed from the routing table and all matching traffic uses the lower priority route. If the link to the gateway for the higher priority route comes back up, BFD adds the route back into the routing table and all matching traffic switches to use the higher priority route.

You can configure BFD for IPv4 and IPv6 static routes.

To configure BFD for static routes:

```
config router {static | static6}
  edit <sequence-number>
    set bfd {enable | disable}
    set device <gateway-out-interface>
  next
end
```

Example

The following example demonstrates the configuration of static routes between two FortiGates. There is a host behind FortiGate 2 with an IP address of 1.1.1.1. FortiGate 1 has multiple paths to reach the host.

To configure static routes:

1. Configure FortiGate 1:

```
config system interface
  edit "port1"
    set vdom "root"
    set ip 10.180.6.237 255.255.240.0
    set allowaccess ping
    set bfd enable
  next
end
```

```
config router bfd
  config neighbor
    edit 10.180.4.136
      set interface "port1"
    next
  end
end
```

2. Configure FortiGate 2:

```
config system interface
  edit "port1"
    set vdom "root"
    set ip 10.180.4.136 255.255.240.0
    set allowaccess ping
    set bfd enable
  next
end
config router bfd
  config neighbor
    edit 10.180.6.237
      set interface "port1"
    next
  end
end
```

3. Configure two static routes:

```
config router static
  edit 2
    set dst 1.1.1.1 255.255.255.255
    set gateway 10.180.4.136
    set device "port1"
    set bfd enable
  next
  edit 3
    set dst 1.1.1.1 255.255.255.255
    set gateway 10.180.2.44
    set distance 20
    set device "port1"
  next
end
```

4. Confirm that BFD neighborship is established:

```
# get router info bfd neighbor
OurAddress      NeighAddress    State      Interface      LDesc/RDesc
10.180.6.237    10.180.4.136    UP         port1          1/1
```

5. Review the active route in the routing table:

```
# get router info routing-table all
S      1.1.1.1/32 [10/0] via 10.180.4.136, port1
C      10.180.0.0/20 is directly connected, port1
```

The route with the lower distance is preferred in the routing table.

If port1 on FortiGate 2 goes down or FortiGate 1 is unable to reach 10.180.4.126, the BFD neighborship will go down.

```
# get router info bfd neighbor
OurAddress      NeighAddress    State           Interface        LDesc/RDesc
10.180.6.237     10.180.4.136    DOWN            port1            1/1
```

With BFD neighborship down, the FortiGate is unable to reach 1.1.1.1/32 through gateway 10.180.4.136. The routing table will be updated so that the route through gateway 10.180.2.44 is active in the routing table.

```
# get router info routing-table all
S      1.1.1.1/32 [20/0] via 10.180.2.44, port1
C      10.180.0.0/20 is directly connected, port1
```

BFD removes a static route from the routing table if the FortiGate cannot reach the route's destination. The static route will be returned to the routing table if the route's destination is restored.

BFD and OSPF

You can configure BFD for Open Shortest Path First (OSPF) on a FortiGate. FortiGate supports BFD for OSPF for both IPv4 and IPv6. BFD must be configured globally and per interface.

To configure BFD for OSPF:

```
config router {ospf | ospf6}
    set bfd {enable | disable}
end
```

To enable BFD on a specific OSPF interface:

```
config router {ospf | ospf6}
    set bfd enable
    config {ospf-interface | ospf6-interface}
        edit <ID>
            set bfd {global | enable | disable}
            set area-id <IP address>
        next
    end
end
```

If BFD is configured when OSPF is not, no BFD packets will be sent. When both BFD and OSPF are configured, the neighbors for both will be the same. Use the following commands to confirm that the neighbor IP addresses match:

```
# get router info ospf neighbor
# get router info bfd neighbor
```

BFD and BGP

While BGP can detect route failures, BFD can be configured to detect these failures more quickly, which allows for faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

The `config router bgp` commands allow you to set the addresses of the neighbor units that are also running BFD. Both units must be configured with BFD in order to use it.

To configure BFD for BGP:

```

config router bgp
    config neighbor
        edit <neighbor-IP-address>
            set bfd {enable | disable}
        next
    end
end

```

BFD for Multihop paths

FortiGate BFD can support neighbors connected over multiple hops. When BFD is down, BGP sessions will be reset and will try to re-establish neighbor connection immediately. See [BFD for multihop path for BGP on page 521](#) for more information.

To configure BFD for multihop paths:

```

config router {bfd | bfd6}
    config multihop-template
        edit <ID>
            set src <IP address/netmask>
            set dst <IP address/netmask>
            set bfd-desired-min-tx <integer>
            set bfd-required-min-rx <integer>
            set bfd-detect-mult <integer>
            set auth-mode {none | md5}
            set md5-key <password>
        next
    end
end

```

Troubleshooting BFD

You can troubleshoot BFD using the following commands:

```

# get router {info | info6} bfd neighbor
# get router {info | info6} bfd requests
# diagnose sniffer packet any <filter> <sniffer count>
# diagnose debug application bfdd <debug level>
# diagnose debug enable

```

BFD for multihop path for BGP

In BFD, a FortiGate can support neighbors connected over multiple hops. When BFD is down, BGP sessions are reset and will try to immediately re-establish neighbor connections. Previously, BFD was only supported when two routers or FortiGates were directly connected on the same network.

```

config router {bfd | bfd6}
    config multihop-template
        edit <ID>
            set src <class_IP/netmask>

```

```

        set dst <class_IP/netmask>
        set bfd-desired-min-tx <integer>
        set bfd-required-min-rx <integer>
        set bfd-detect-mult <integer>
        set auth-mode {none | md5}
        set md5-key <password>
    next
end
end

```

src <class_IP/netmask>	Enter the source prefix.
dst <class_IP/netmask>	Enter the destination prefix.
bfd-desired-min-tx <integer>	Set the BFD desired minimal transmit interval, in milliseconds (100 - 30000, default = 250).
bfd-required-min-rx <integer>	Set the BFD required minimal transmit interval, in milliseconds (100 - 30000, default = 250).
bfd-detect-mult <integer>	Set the BFD detection multiplier (3 - 50, default = 3).
auth-mode {none md5}	Set the authentication mode (none or meticulous MD5).
md5-key <password>	Enter the password.

Example

This example includes IPv4 and IPv6 BFD neighbor configurations. The BFD neighbor is also a BGP neighbor that is in a different AS.

To configure BFD with multihop BGP paths:

1. Enable BFD on all interfaces:

```

config system settings
    set bfd enable
end

```

2. Enable BFD on port1 and ignore the global configuration:

```

config system interface
    edit "port1"
        set bfd enable
    next
end

```

3. Configure the BGP neighbors:

```

config router bgp
    set as 65412
    set router-id 1.1.1.1
    config neighbor
        edit "172.16.201.2"
            set bfd enable
            set ebgp-enforce-multihop enable
            set soft-reconfiguration enable
            set remote-as 65050
        next
        edit "2000:172:16:201::2"
            set bfd enable
            set ebgp-enforce-multihop enable
            set soft-reconfiguration enable
            set remote-as 65050
        next
    end
end

```

4. Configure the IPv4 BFD:

```

config router bfd
    config multihop-template
        edit 1
            set src 172.16.200.0 255.255.255.0
            set dst 172.16.201.0 255.255.255.0
            set auth-mode md5
            set md5-key *****
        next
    end
end

```

5. Configure the IPv6 BFD:

```

config router bfd6
    config multihop-template
        edit 1
            set src 2000:172:16:200::/64
            set dst 2000:172:16:201::/64
        next
    end
end

```

Testing the connection**1. Verify the BFD status for IPv4 and IPv6:**

```

# get router info bfd requests
BFD Peer Requests:
    client types(ct in 0x): 01=external 02=static
                          04=ospf 08=bgp 10=pim-sm
src=172.16.200.1      dst=172.16.201.2      ct=08 ifi=9 type=SM

# get router info bfd neighbor
OurAddress      NeighAddress      State      Interface      LDesc/RDesc
172.16.200.1    172.16.201.2    UP         port1          5/3/M

```

```
# get router info6 bfd requests
BFD Peer Requests:
  client types(ct in 0x): 01=external 02=static
                        04=ospf 08=bgp 10=pim-sm
src=2000:172:16:200::1
dst=2000:172:16:201::2
ct=08 ifi=9 type=SM

# get router info6 bfd neighbor
OurAddress: 2000:172:16:200::1
NeighAddress: 2000:172:16:201::2
State: UP Interface: port1 Desc: 6/4 Multi-hop
```

2. Verify the BGP status and the BGP routing table:

```
# get router info bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 11
3 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
172.16.201.2	4	65050	185	187	10	0	0	00:54:20	4
2000:172:16:201::2	4	65050	159	160	10	0	0	00:54:24	4

Total number of neighbors 2

```
# get router info routing-table bgp
Routing table for VRF=0
B      172.28.1.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
B      172.28.2.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
B      172.28.5.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
B      172.28.6.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
```

```
# get router info6 bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 8
3 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
172.16.201.2	4	65050	185	187	7	0	0	00:54:24	3
2000:172:16:201::2	4	65050	159	160	7	0	0	00:54:28	3

Total number of neighbors 2

```
# get router info6 routing-table bgp
Routing table for VRF=0
B      2000:172:28:1::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:54:40
B      2000:172:28:2::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:54:40
B      2000:172:28:3::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:54:40
```

3. Simulate a disruption to the BFD connection. The BFD neighbor is lost:

```
# get router info bfd neighbor
OurAddress      NeighAddress    State      Interface      LDesc/RDesc

# get router info6 bfd neighbor
```

4. The BGP neighbor is reset, and the FortiGate attempts to re-establish a connection with the neighbor. The timers are reset once the neighbor connection is re-established:

```
# get router info bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 12
4 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
172.16.201.2	4	65050	189	192	11	0	0	00:00:11	4
2000:172:16:201::2	4	65050	165	167	12	0	0	00:00:08	4

Total number of neighbors 2

```
# get router info6 bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 10
4 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
172.16.201.2	4	65050	189	192	8	0	0	00:00:15	3
2000:172:16:201::2	4	65050	165	167	9	0	0	00:00:12	3

Total number of neighbors 2

5. The BGP routes are learned again, and there are new timers in the route tables:

```
# get router info routing-table bgp
Routing table for VRF=0
B      172.28.1.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15
B      172.28.2.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15
B      172.28.5.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15
B      172.28.6.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15
```

```
# get router info6 routing-table bgp
Routing table for VRF=0
B      2000:172:28:1::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:00:13
B      2000:172:28:2::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:00:13
B      2000:172:28:3::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:00:13
```

Routing objects

The following objects can be configured from the *Network > Routing Objects* page:

- [Route maps on page 526](#)
- [Access lists on page 528](#)
- [Prefix lists on page 531](#)
- [AS path lists on page 533](#)
- [Community lists on page 534](#)

Route maps

Route maps are a powerful tool to apply custom actions to dynamic routing protocols based on specific conditions. They are used primarily in BGP to manipulate routes advertised by the FortiGate (*route-map-out*) or received routes from other BGP routers (*route-map-in*).

Route maps can be used in OSPF for conditional *default-information-originate*, filtering external routes, or matching specific routes for redistribution. Similarly, route maps can be used by RIP to match routes for redistribution.

A route map may have multiple rules that are processed from the top down. Each rule has an action to permit or deny. The rules have criteria for matching a route based on various attributes, or setting attributes based on a matched route.

For example, a route map can be used to match BGP routes with a certain community string, and then set an AS path to the matching route. This can be applied to a BGP neighbor by configuring the route map in setting for that neighbor.

To configure a route map that matches criteria based on other routing objects:

```
config router route-map
  edit <name>
    config rule
      edit <id>
        set action {permit | deny}
        set match-as-path <string>
        set match-community <string>
        set match-ip-address <string>
        set match-ip6-address <string>
        set match-ip-nexthop <string>
        set match-ip6-nexthop <string>
      next
    end
  next
end
```

match-as-path <string>	Match a BGP AS path list.
match-community <string>	Match a BGP community list.
match-ip-address <string>	Match an IPv4 address permitted by <i>access-list</i> or <i>prefix-list</i> .
match-ip6-address <string>	Match an IPv6 address permitted by <i>access-list6</i> or <i>prefix-list6</i> .
match-ip-nexthop <string>	Match a next hop IPv4 address passed by <i>access-list</i> or <i>prefix-list</i> .
match-ip6-nexthop <string>	Match a next hop IPv6 address passed by <i>access-list6</i> or <i>prefix-list6</i> .

Route maps can be used by various routing protocols, such as RIP, OSPF, and BGP.

To use a route map with RIP:

```
config router rip
  config redistribute
    edit <name>
      set routemap <string>
    next
  end
end
```

To use a route map with OSPF:

```
config router ospf
  set default-information-route-map <string>
  set distribute-route-map-in <string>
  config redistribute <string>
    set routemap <string>
  end
end
```

default-information-route-map <string>	Enter the default information route map.
distribute-route-map-in <string>	Enter the route map to filter incoming external routes.
redistribute <string>	Configure the redistribute protocol.

To use a route map with BGP:

```
config router bgp
  config neighbor
    edit <ip>
      set route-map-in <string>
      set route-map-in6 <string>
      set route-map-in-vpnv4 <string>
      set route-map-out <string>
      set route-map-out-preferable <string>
      set route-map-out6 <string>
      set route-map-out6-preferable <string>
      set route-map-out-vpnv4 <string>
      set route-map-out-vpnv4-preferable <string>
    next
  end
  config network
    edit <id>
      set prefix <IP/netmask>
      set route-map <string>
    next
  end
  config redistribute <string>
    set route-map <string>
  end
end
```

<code>route-map-in <string></code>	Enter the IPv4 inbound route map filter.
<code>route-map-in6 <string></code>	Enter the IPv6 inbound route map filter.
<code>route-map-in-vpnv4 <string></code>	Enter the VPNv4 inbound route map filter.
<code>route-map-out <string></code>	Enter the IPv4 outbound route map filter.
<code>route-map-out-preferable <string></code>	Enter the IPv4 outbound route map filter if the peer is preferred.
<code>route-map-out6 <string></code>	Enter the IPv6 outbound route map filter.
<code>route-map-out6-preferable <string></code>	Enter the IPv6 outbound route map filter if the peer is preferred.
<code>route-map-out-vpnv4 <string></code>	Enter the VPNv4 outbound route map filter.
<code>route-map-out-vpnv4- preferable <string></code>	Enter the VPNv4 outbound route map filter if the peer is preferred.
<code>route-map <string></code>	Enter the route map to modify the generated route.
<code>redistribute <string></code>	Configure the redistribute protocol.

To use a route map with BGP conditional advertisement:

```

config router bgp
    set as <AS_number>
    config neighbor
        edit <ip>
            set remote-as <AS_number>
            config conditional-advertise
                edit <advertise-routemap>
                    set condition-routemap <name1>, <name2>, ...
                    set condition-type {exist | non-exist}
                next
            end
        next
    end
end

```

<code><advertise-routemap></code>	Edit the advertising route map.
<code>condition-routemap <name1>, <name2>, ...</code>	Enter the list of conditional route maps.

Access lists

Access lists are simple lists used for filtering routes based on a prefix consisting of an IPv4 or IPv6 address and netmask.

To configure an IPv4 access list:

```

config router access-list
    edit <name>

```

```

    config rule
        edit <id>
            set action {permit | deny}
            set prefix <IPv4_address>
            set wildcard <wildcard_filter>
            set exact-match {enable | disable}
        next
    end
next
end

```

To configure an IPv6 access list:

```

config router access-list6
    edit <name>
        config rule
            edit <id>
                set action {permit | deny}
                set prefix <IPv6_address>
                set exact-match {enable | disable}
            next
        end
    next
end

```

In RIP, an access list can be used in the `distribute-list` setting to filter received or advertised routes, or in an `offset-list` to offset the hop count metric for a specific prefix.

To use an access list in RIP:

```

config router rip
    config distribute-list
        edit <id>
            set direction {in | out}
            set listname <string>
        next
    end
    config offset-list
        edit <id>
            set direction {in | out}
            set access-list <string>
            set offset <integer>
        next
    end
end

```

<code>listname <string></code>	Enter the distribute access or prefix list name.
<code>access-list <string></code>	Enter the access list name.

In OSPF, an access list can be used in the `distribute-list-in` setting to act as a filter to prevent a certain route from being inserted into the routing table. An access list can also be used in the `distribute-list` to filter the routes that can be distributed from other protocols.

To use an access list in OSPF:

```

config router ospf
  set distribute-list-in <string>
  config distribute-list
    edit <id>
      set access-list <string>
      set protocol {connected | static | rip}
    next
  end
end

```

distribute-list-in <string>	Enter the filter for incoming routes.
--------------------------------	---------------------------------------

access-list <string>	Enter the access list name.
----------------------	-----------------------------

In BGP, an access list can be used to filter updates from a neighbor or to a neighbor.

To use an access list in BGP:

```

config router bgp
  config neighbor
    edit <ip>
      set distribute-list-in <string>
      set distribute-list-in6 <string>
      set distribute-list-in-vpnv4 <string>
      set distribute-list-out <string>
      set distribute-list-out6 <string>
      set distribute-list-out-vpnv4 <string>
    next
  end
end

```

distribute-list-in <string>	Enter the filter for IPv4 updates from this neighbor.
--------------------------------	---

distribute-list-in6 <string>	Enter the filter for IPv6 updates from this neighbor.
---------------------------------	---

distribute-list-in-vpnv4 <string>	Enter the filter for VPNv4 updates from this neighbor.
--------------------------------------	--

distribute-list-out <string>	Enter the filter for IPv4 updates to this neighbor.
---------------------------------	---

distribute-list-out6 <string>	Enter the filter for IPv6 updates to this neighbor.
----------------------------------	---

distribute-list-out-vpnv4 <string>	Enter the filter for VPNv4 updates to this neighbor.
---------------------------------------	--

In a route map, an access list can be used to match IP addresses and next hops.

To use an access list in a route map:

```

config router route-map
  edit <name>

```

```

    config rule
        edit <id>
            set match-ip-address <string>
            set match-ip6-address <string>
            set match-ip-nexthop <string>
            set match-ip6-nexthop <string>
        next
    end
next
end

```

match-ip-address <string>	Match an IPv4 address permitted by access-list or prefix-list.
match-ip6-address <string>	Match an IPv6 address permitted by access-list6 or prefix-list6.
match-ip-nexthop <string>	Match a next hop IPv4 address passed by access-list or prefix-list.
match-ip6-nexthop <string>	Match a next hop IPv6 address passed by access-list6 or prefix-list6.

Prefix lists

Similar to access lists, prefix lists are simple lists used for filtering routes based on a prefix consisting of an IPv4 or IPv6 address and netmask, but they use settings to specify the minimum (*ge*, greater than or equal) and maximum (*le*, less than or equal) prefix length to be matched. For example, a prefix of 10.0.0.0/8 with a *ge* of 16 will match anything in the 10.0.0.0/8 network with /16 or above; 10.10.0.0/16 will match, and 10.10.0.0/12 will not match.

To configure an IPv4 prefix list:

```

config router prefix-list
    edit "prefix-list1"
        config rule
            edit 1
                set action {permit | deny}
                set prefix <IPv4_address>
                set ge <integer>
                set le <integer>
            next
        end
    next
end

```

To configure an IPv6 prefix list:

```

config router prefix-list6
    edit "prefix-list-IPv6"
        config rule
            edit 1
                set action {permit | deny}
                set prefix6 <IPv6_address>
                set ge <integer>
                set le <integer>
            next
        end
    end

```

```

    next
end

```

In RIP, an prefix list can be used in the `distribute-list` setting to filter received or advertised routes.

To use a prefix list in RIP:

```

config router rip
    config distribute-list
        edit <id>
            set listname <string>
        next
    end
end

```

<code>listname <string></code>	Enter the distribute access or prefix list name.
--------------------------------------	--

In OSPF, a prefix list can be used in the `distribute-list-in` setting to act as a filter to prevent a certain route from being inserted into the routing table.

To use a prefix list in OSPF:

```

config router ospf
    set distribute-list-in <string>
end

```

<code>distribute-list-in <string></code>	Enter the filter for incoming routes.
--	---------------------------------------

In BGP, a prefix list can be used to filter updates from a neighbor or to a neighbor.

To use a prefix list in BGP:

```

config router bgp
    config neighbor
        edit <ip>
            set prefix-list-in <string>
            set prefix-list-in6 <string>
            set prefix-list-in-vpnv4 <string>
            set prefix-list-out <string>
            set prefix-list-out6 <string>
            set prefix-list-out-vpnv4 <string>
        next
    end
end

```

<code>prefix-list-in <string></code>	Enter the IPv4 inbound filter for updates from this neighbor.
<code>prefix-list-in6 <string></code>	Enter the IPv6 inbound filter for updates from this neighbor.
<code>prefix-list-in-vpnv4 <string></code>	Enter the inbound filter for VPNv4 updates from this neighbor.
<code>prefix-list-out <string></code>	Enter the IPv4 outbound filter for updates to this neighbor.

prefix-list-out6 <string>	Enter the IPv6 outbound filter for updates to this neighbor.
prefix-list-out-vpn4 <string>	Enter the outbound filter for VPNv4 updates to this neighbor.

In a route map, a prefix list can be used to match IP addresses and next hops.

To use a prefix list in a route map:

```
config router route-map
  edit <name>
    config rule
      edit <id>
        set match-ip-address <string>
        set match-ip6-address <string>
        set match-ip-nexthop <string>
        set match-ip6-nexthop <string>
      next
    end
  next
end
```

match-ip-address <string>	Match an IPv4 address permitted by access-list or prefix-list.
match-ip6-address <string>	Match an IPv6 address permitted by access-list6 or prefix-list6.
match-ip-nexthop <string>	Match a next hop IPv4 address passed by access-list or prefix-list.
match-ip6-nexthop <string>	Match a next hop IPv6 address passed by access-list6 or prefix-list6.

AS path lists

AS path lists use regular expressions to compare and match the AS_PATH attribute for a BGP route. They can be used to filter inbound or outbound routes from a BGP neighbor, or as matching criteria in a route map to match an AS_PATH in a BGP route.

To configure an AS path list:

```
config router aspath-list
  edit <name>
    config rule
      edit <id>
        set action {deny | permit}
        set regexp <string>
      next
    end
  next
end
```

To use an AS path list in BGP:

```
config router bgp
  config neighbor
```

```

        edit <ip>
            set filter-list-in <string>
            set filter-list-in6 <string>
            set filter-list-out <string>
            set filter-list-out6 <string>
        next
    end
end

```

filter-list-in <string>	Enter the BGP filter for IPv4 inbound routes.
filter-list-in6 <string>	Enter the BGP filter for IPv6 inbound routes.
filter-list-out <string>	Enter the BGP filter for IPv4 outbound routes.
filter-list-out6 <string>	Enter the BGP filter for IPv6 outbound routes.

To use an AS path list in a route map:

```

config router route-map
    edit <name>
        config rule
            edit <id>
                set match-as-path <string>
            next
        end
    next
end

```

match-as-path <string>	Match a BGP AS path list.
------------------------	---------------------------

Community lists

Community lists provide a means to filter BGP routes using a community string. They can be applied in a route map to match routes that have the community string defined in the community list.

To configure a community list:

```

config router community-list
    edit <name>
        set type {standard | expanded}
        config rule
            edit <id>
                set action {deny | permit}
                set regexp <string>
                set match <string>
            next
        end
    next
end

```

To use a community list in a route map to match a BGP community:

```
config router route-map
  edit <name>
    config rule
      edit <id>
        set match-community <string>
      next
    end
  next
end
```

match-community <string> Match a BGP community list.

In an SD-WAN deployment, a remote BGP router or spoke may communicate a preferred interface or path to route traffic using a community string. See [Using BGP tags with SD-WAN rules on page 864](#) and [Controlling traffic with BGP route mapping and service rules on page 870](#) for examples.

Multicast

The following topics include information about multicast:

- [Multicast routing and PIM support on page 535](#)
- [Configuring multicast forwarding on page 536](#)

Multicast routing and PIM support

Multicasting (also called IP multicasting) consists of using a single multicast source to send data to many receivers. Multicasting can be used to send data to many receivers simultaneously while conserving bandwidth and reducing network traffic. Multicasting can be used for one-way delivery of media streams to multiple receivers and for one-way data transmission for news feeds, financial information, and so on. Many dynamic routing protocols such as RIPv2, OSPF, and EIGRP use multicasting to share hello packets and routing information.

A FortiGate can operate as a Protocol Independent Multicast (PIM) version 2 router. FortiGates support PIM sparse mode ([RFC 4601](#)) and PIM dense mode ([RFC 3973](#)), and can service multicast servers or receivers on the network segment to which a FortiGate interface is connected. Multicast routing is not supported in transparent mode.

To support PIM communications, the sending and receiving applications, and all connecting PIM routers in between, must be enabled with PIM version 2. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations. To enable source-to-destination packet delivery, sparse mode or dense mode must be enabled on the PIM router interfaces. Sparse mode routers cannot send multicast messages to dense mode routers. If the FortiGate is located between a source and a PIM router, between two PIM routers, or is connected directly to a receiver, you must manually create a multicast policy to pass encapsulated (multicast) packets or decapsulated data (IP traffic) between the source and destination.

PIM domains

A PIM domain is a logical area comprising a number of contiguous networks. The domain contains at least one bootstrap router (BSR), and if sparse mode is enabled, a number of rendezvous points (RPs) and designated routers (DRs). When PIM is enabled, the FortiGate can perform any of these functions at any time as configured.

A PIM domain can be configured in the GUI by going to *Network > Multicast*, or in the CLI using `config router multicast`. Note that PIM version 2 must be enabled on all participating routers between the source and receivers. Use `config router multicast` to set the global operating parameters.

When PIM is enabled, the FortiGate allocates memory to manage mapping information. The FortiGate communicates with neighboring PIM routers to acquire mapping information and, if required, processes the multicast traffic associated with specific multicast groups.

Instead of sending multiple copies of generated IP traffic to more than one specific IP destination address, PIM-enabled routers encapsulate the data and use a Class D multicast group address (224.0.0.0 to 239.255.255.255) to forward multicast packets to multiple destinations. A single stream of data can be sent because one destination address is used. Client applications receive multicast data by requesting that the traffic destined for a certain multicast group address be delivered to them.

Configuring multicast forwarding

There is sometimes confusion between the terms forwarding and routing. These two functions should not take place at the same time. Multicast forwarding should be enabled when the FortiGate is in NAT mode and you want to forward multicast packets between multicast routers and receivers. However, this function should not be enabled when the FortiGate itself is operating as a multicast router, or has an applicable routing protocol that uses multicast.

Multicast forwarding is not supported on enhanced MAC VLAN interfaces. To use multicast with enhanced MAC VLAN interfaces, use PIM ([Multicast routing and PIM support on page 535](#)).

There are two steps to configure multicast forwarding:

1. [Enabling multicast forwarding on page 536](#)
2. [Configuring multicast policies on page 537](#)

Enabling multicast forwarding

Multicast forwarding is enabled by default. If a FortiGate is operating in transparent mode, adding a multicast policy enables multicast forwarding. In NAT mode you must use the `multicast-forward` setting to enable or disable multicast forwarding.

Multicast forwarding in NAT mode

When `multicast-forward` is enabled, the FortiGate forwards any multicast IP packets in which the TTL is 2 or higher to all interfaces and VLAN interfaces, except the receiving interface. The TTL in the IP header will be reduced by 1. Even though the multicast packets are forwarded to all interfaces, you must add multicast policies to allow multicast packets through the FortiGate.

To enable multicast forwarding in NAT mode:

```
config system settings
    set multicast-forward enable
end
```

Prevent the TTL for forwarded packets from being changed

You can use the `multicast-ttl-notchange` option so that the FortiGate does not increase the TTL value for forwarded multicast packets. Use this option only if packets are expiring before reaching the multicast router.

To prevent the TTL for forwarded packets from being changed:

```
config system settings
    set multicast-ttl-notchange enable
end
```

Disable multicast traffic from passing through the FortiGate without a policy check in transparent mode

In transparent mode, the FortiGate does not forward frames with multicast destination addresses. The FortiGate should not interfere with the multicast traffic used by routing protocols, streaming media, or other multicast communication. To avoid any issues during transmission, you can disable `multicast-skip-policy` and configure multicast security policies.

To disable multicast traffic from passing through the FortiGate without a policy check in transparent mode:

```
config system settings
    set multicast-skip-policy disable
end
```

Configuring multicast policies

Multicast packets require multicast policies to allow packets to pass from one interface to another. Similar to firewall policies, in a multicast policy you specify the source and destination interfaces, and the allowed address ranges for the source and destination addresses of the packets. You can also use multicast policies to configure source NAT and destination NAT for multicast packets.

Keep the following in mind when configuring multicast policies:

- The matched forwarded (outgoing) IP multicast source IP address is changed to the configured IP address.
- The `snat` setting is optional. Use it when SNAT is needed.

IPv4 and IPv6 multicast policies can be configured in the GUI. Go to *System > Feature Visibility*, and enable *Multicast Policy* and *IPv6*.

Sample basic policy

In this basic policy, multicast packets received on an interface are flooded unconditionally to all interfaces on the forwarding domain, except the incoming interface.

```
config firewall multicast-policy
  edit 1
    set srcintf "any"
    set dstintf "any"
    set srcaddr "all"
    set dstaddr "all"
  next
end
```

The destination address (`dstaddr`) is a multicast address object. The `all` option corresponds to all multicast addresses in the range 224.0.0.0-239.255.255.255.

Sample policy with specific source and destination interfaces

This multicast policy only applies to the source port `wan1` and the destination port `internal`.

```
config firewall multicast-policy
  edit 1
    set srcintf "wan1"
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "all"
  next
end
```

Sample policy with specific source address object

In this policy, packets are allowed to flow from `wan1` to `internal`, and sourced by the address 172.20.120.129, which is represented by the `example_addr-1` address object.

```
config firewall multicast-policy
  edit 1
    set srcintf "wan1"
    set dstintf "internal"
    set srcaddr "example_addr-1"
    set dstaddr "all"
  next
end
```

Sample detailed policy

This policy accepts multicast packets that are sent from a PC with IP address 192.168.5.18 to destination address range 239.168.4.0-255. The policy allows the multicast packets to enter the `internal` interface and then exit the `external` interface. When the packets leave the external interface, their source address is translated to 192.168.18.10.

```
config firewall address
  edit "192.168.5.18"
    set subnet 192.168.5.18 255.255.255.255
  next
end
```

```

config firewall multicast-address
    edit "239.168.4.0"
        set start-ip 239.168.4.0
        set end-ip 239.168.4.255
    next
end

config firewall multicast-policy
    edit 1
        set srcintf "internal"
        set dstintf "external"
        set srcaddr "192.168.5.18"
        set dstaddr "239.168.4.0"
        set snat enable
        set snat-ip 192.168.18.10
    next
end

```

To configure multicast policies in the GUI, enable *Multicast Policy* in *System > Feature Visibility*.

Using multi VDOM mode

When using multi VDOM mode, it is important to avoid causing a multicast network loop by creating an all-to-all multicast policy. By default, on models that support NPU virtual links, changing the `vdom-mode` to `multi-vdom` will create a pair of `np0_vlink0` and `np0_vlink1` interfaces in the same root VDOM. By virtue of the all-to-all multicast policy and the fact the `np0_vlink` interfaces are virtually connected, it forms a multicast network loop.

Therefore, when using multi VDOM mode:

1. Ensure there is no existing all-to-all multicast policy before changing to multi VDOM mode.
2. If an all-to-all multicast policy must be defined, ensure that no two connected interfaces (such as `np0_vlink0` and `np0_vlink1`) belong in the same VDOM.

This configuration will result in a multicast loop:

```

config system global
    set vdom-mode multi-vdom
end

config firewall multicast-policy
    edit 1
        set logtraffic enable
        set srcintf "any"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
    next
end

show system interface
config system interface
    edit "np0_vlink0"
        set vdom "root"
        set type physical
    next
end

```

```
next
edit "np0_vlink1"
    set vdom "root"
    set type physical
next
end
```

FortiExtender

There are two configuration modes available on the FortiGate for FortiExtender integration: WAN extension mode and LAN extension mode.

For information about configuring FortiExtender, see the FortiExtender [Admin Guide \(FGT-Managed\)](#) and [Admin Guide \(Standalone\)](#).

WAN extension mode

In WAN extension mode, the FortiExtender works as an extended WAN interface in IP pass-through mode. The FortiGate manages FortiExtender over the CAPWAP protocol in IP pass-through mode, and is integrated into FortiOS as a manageable interface.

Sample configurations in WAN extension mode could include connecting a FortiExtender to two FortiGates in HA active-passive mode, or connecting two FortiExtenders to two FortiGates in HA active-active mode to provide dual active redundancy for wireless WAN access.

For more information, see [FortiExtender and FortiGate integration](#) in the FortiExtender (Managed) Administration Guide.

LAN extension mode

The LAN extension configuration mode allows FortiExtender to provide remote thin edge connectivity back to the FortiGate over a backhaul connection. A FortiExtender deployed at a remote location will discover the FortiGate access controller (AC) and form an IPsec tunnel (or multiple tunnels when multiple links exist on the FortiExtender) back to the FortiGate. A VXLAN is established over the IPsec tunnels to create an L2 network between the FortiGate and the network behind the remote FortiExtender.

For more information, see [FortiExtender as FortiGate LAN extension](#) in the FortiExtender (Managed) Administration Guide.

Adding a FortiExtender

To add a FortiExtender to the FortiGate, create a virtual FortiExtender interface, then add a FortiExtender and assign the interface to the modem. Like other interface types, the FortiExtender interface can be used in static routes, SD-WAN (see [Manage dual FortiExtender devices](#)), policies, and other functions.

To create a virtual FortiExtender interface in the GUI:

1. Go to *Network > Interfaces* and click *Create New > FortiExtender*.
2. Enter a name for the interface.
3. Configure the remaining settings as needed. See [Interface settings on page 163](#) for more details.

4. Click *OK*.

To add a FortiExtender in the GUI:

1. Go to *Network > FortiExtender* and click *Create New > Extenders*.
2. Enter your FortiExtender's serial number in the *Serial number* field.
3. Optionally, set an *Alias* for the FortiExtender.
4. In the *State* section, enable *Authorized*.
5. Set *Interface* to the FortiExtender interface.

6. Configure the remaining setting as required. See the [FortiExtender Administration Guide \(FGT-Managed\)](#) for more information.

7. Click **OK**.
8. In the extenders list, right-click on the FortiExtender and select *Diagnostics and Tools* to review the modem and SIM status, and other details about the FortiExtender.

To create a virtual FortiExtender interface in the CLI:

```
config system interface
  edit "fext"
    set vdom "root"
    set mode dhcp
    set allowaccess ping https speed-test
    set type fext-wan
    set estimated-upstream-bandwidth 1000
    set estimated-downstream-bandwidth 500
  next
end
```

To configure the FortiExtender in the CLI:

```
config extender-controller extender
  edit "FX211E0000000000"
    set id "FX211E0000000000"
    set authorized enable
    config modem1
      set ifname "fext"
    end
  next
end
```

To verify the modem settings in the CLI:

```
get extender modem-status FX211E0000000000 1
Modem 0:
  physical_port:      2-1.2
  manufacture:       Sierra Wireless, Incorporated
  product:            Sierra Wireless, Incorporated
  ....
```

Direct IP support for LTE/4G

Direct IP is a public IP address that is assigned to a computing device, which allows the device to directly access the internet.

When an LTE modem is enabled in FortiOS, a DHCP interface is created. As a result, the FortiGate can acquire direct IP (which includes IP, DNS, and gateway) from the LTE network carrier.

Since some LTE modems require users to input the access point name (APN) for the LTE network, the LTE modem configuration allows you to set the APN.

LTE modems can only be enabled by using the CLI.

DHCP relay packet flow through the modem interface can be enabled from the CLI using the `dhcp-relay` command.

```
config system lte-modem
    set dhcp-relay enable
end
```

To enable direct IP support using the CLI:

1. Enable the LTE modem:

```
config system lte-modem
    set status enable
end
```

2. Check that the LTE interface was created:

```
config system interface
    edit "wan"
        set vdom "root"
        set mode dhcp
        set status down
        set distance 1
        set type physical
        set snmp-index 23
    next
end
```

Shortly after the LTE modem joins its carrier network, `wan` is enabled and granted direct IP:

```
config system interface
    edit wan
        get
name                : wan
....
ip                  : 100.112.75.43 255.255.255.248
....
status              : up
```

```
....
defaultgw          : enable
DHCP Gateway       : 100.112.75.41
Lease Expires      : Thu Feb 21 19:33:27 2019
dns-server-override : enable
Acquired DNS1      : 184.151.118.254
Acquired DNS2      : 70.28.245.227
....
```

PCs can reach the internet via the following firewall policy:

```
config firewall policy
edit 5
    set name "LTE"
    set srcintf "port9"
    set dstintf "wwan"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set fsso disable
    set nat enable
next
end
```

Sample LTE interface

When an LTE modem is enabled, you can view the LTE interface in the GUI and check the acquired IP, DNS, and gateway.

To view the LTE interface in the GUI:

1. Go to *Network > Interfaces*.
2. Double-click the LTE interface (*wwan*) to view the properties.
3. Look in the *Address* section to see the *Obtained IP/Netmask*, *Acquired DNS*, and *Default Gateway*.
4. Click *Return*.

To configure the firewall policy that uses the LTE interface:

1. Go to *Policy & Objects > Firewall Policy*.
2. Edit the LTE policy.
3. In the *Outgoing Interface* field, select the interface (*wwan* in this example).
4. Configure the rest of the policy as needed.

The screenshot shows the 'New Policy' configuration window in FortiOS. The configuration is as follows:

- Name:** LTE
- Incoming Interface:** modem
- Outgoing Interface:** wwan
- Source:** all
- Destination:** all
- Schedule:** always
- Service:** ALL
- Action:** ACCEPT (checked), DENY, IPsec
- Inspection Mode:** Flow-based (selected), Proxy-based
- Firewall/Network Options:** NAT is enabled (checked).

The 'Additional Information' panel on the right includes an 'API Preview' button and a 'Documentation' section with links to 'Online Help', 'Video Tutorials', and 'Consolidated Policy Configuration'.

5. Click OK.

Limitations

- Most LTE modems have a preset APN in their SIM card. Therefore, the APN does not need to be set in the FortiOS configuration. In cases where the internet cannot be accessed, consult with your carrier and set the APN in the LTE modem configuration (for example, inet.bell.ca):

```
config system lte-modem
  set status enable
  set apn "inet.bell.ca"
end
```

- Some models, such as the FortiGate 30E-3G4G, have built-in LTE modems. In this scenario, the LTE modem is enabled by default. The firewall policy via the LTE interface is also created by default. Once you plug in a SIM card, your network devices can connect to the internet.

Sample FortiGate 30E-3G4G default configuration:

```
config system lte-modem
  set status enable
  set extra-init ''
  set manual-handover disable
  set force-wireless-profile 0
  set authtype none
  set apn ''
  set modem-port 255
  set network-type auto
  set auto-connect disable
  set gpsd-enabled disable
  set data-usage-tracking disable
  set gps-port 255
end

config firewall policy
....
edit 3
  set srcintf "internal"
```

```

    set dstintf "wwan"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
  next
end

```

Active SIM card switching

FortiGates with a cellular modem and dual SIM card can switch in real time from the active SIM card to the passive SIM card when any of the following issues arise with the active SIM card:

- Ping link monitor fails. The SIM switch time depends on the link monitor parameters set.
- An active SIM card cannot be detected. The SIM switch time is about 20 seconds after the SIM card is no longer detected.
- A modem disconnection is detected, and a specified interval has elapsed. The SIM switch time occurs after the specified interval.

SIM card switching events are captured in the FortiGate event log.

In most cases, SIM cards come with the wireless carrier's APN, which is automatically retrieved at the first connection of the LTE modem. For these cases, you can use SIM cards for different wireless carriers in SIM slot 1 and slot 2.

When one or both SIM cards require their APN settings to be configured on the FortiGate, then both SIM cards should be for the same wireless carrier because `config system lte-modem` currently only supports a single `set apn <apn> setting`.

The following command and options can be used to configure this feature:

```

config system lte-modem
  config sim-switch
    set by-sim-state {enable | disable}
    set by-connection-state {enable | disable}
    set by-link-monitor {enable | disable}
    set link-monitor <link-monitor-name>
    set sim-switch-log-alert-interval <interval>
    set sim-switch-log-alert-threshold <threshold>
    set modem-disconnection-time <integer>
  end
end

```

```
by-sim-state {enable |
  disable}
```

Enable switching based on active SIM card state:

- **enable:** switch to the passive SIM card whenever FortiGate cannot detect the active SIM card, such as when the active SIM card is ejected.
- **disable:** do not switch SIM cards based on state.

```
by-connection-state
  {enable | disable}
```

Enable switching based on the connection state of the active SIM card:

	<ul style="list-style-type: none"> • enable: switch to the passive SIM card whenever FortiGate detects a modem signal loss after the <code>modem-disconnection-time</code> expires. • disable: do not switch SIM cards based on the connection state.
<code>by-link-monitor {enable disable}</code>	<p>Enable switching when a configured link monitor fails:</p> <ul style="list-style-type: none"> • enable: switch to the passive SIM card when a link monitor configured with <code>link-monitor-name</code> fails. • disable: do not switch SIM cards based on the failure of a configured link monitor.
<code>link-monitor <link-monitor-name></code>	Specify the name of the link monitor to use with <code>by-link-monitor</code> .
<code>sim-switch-log-alert-interval <interval></code>	Identify what number of constant SIM card switch events will trigger an event log after the threshold in <code>sim-switch-log-alert-threshold</code> is met.
<code>sim-switch-log-alert-threshold</code>	Specify how many minutes to wait before creating an event log when the number of SIM card switches defined in <code>sim-switch-log-alert-interval</code> is met.
<code>modem-disconnection-time <integer></code>	Specify how many seconds to wait before switching over to the passive SIM card when <code>by-connection-state</code> is enabled and a modem signal loss is detected.

Example 1

In this example, automatic SIM card switching is disabled. When disabled, the SIM card only works in the default slot1, but you can manually switch the SIM card to slot2. Event logs include details about the SIM card switch.

To manually switch a SIM card:

1. Disable automatic SIM card switching:

```
config system lte-modem
    config sim-switch
        set by-sim-state disable
        set by-connection-state disable
        set by-link-monitor disable
        set sim-slot 1
    end
end
```

2. Manually switch the SIM card from slot1 to slot2, and run the following command:

```
# execute lte-modem sim-switch
```

The SIM card switch may take a few seconds. You can run `diagnose system lte-modem sim-info` to check the results.

The following log is generated after unplugging an active SIM card:

```
7: date=2023-05-02 time=10:41:05 eventtime=1683049264795418820 tz="-0700"
logid="0100046518" type="event" subtype="system" level="information" vd="root"
logdesc="LTE modem active SIM card switch event" msg="LTE modem active SIM card slot
changed to 2 by user."
```

Example 2

In this section, automatic SIM card switching is enabled and configured to switch based on SIM state, connection state, or link monitor state, and it includes example event logs for each scenario.

To enable automatic SIM card switching by SIM state:

1. Enable automatic SIM card switching by SIM state:

```
config system lte-modem
    config sim-switch
        set by-sim-state enable
    end
end
```

With this configuration, the second SIM card becomes active when the active SIM card is no longer detected, for example, if the active SIM card is ejected. The following event logs are generated:

```
5: date=2023-04-28 time=17:27:27 eventtime=1682728046989682780 tz="-0700"
logid="0100046513" type="event" subtype="system" level="information" vd="root"
logdesc="LTE modem data link connection event" msg="LTE modem data link changed from
QMI_WDS_CONNECTION_STATUS_DISCONNECTED to QMI_WDS_CONNECTION_STATUS_CONNECTED"

6: date=2023-04-28 time=17:27:17 eventtime=1682728036493684280 tz="-0700"
logid="0100046512" type="event" subtype="system" level="information" vd="root"
logdesc="LTE modem SIM card state event" msg="LTE modem SIM card change from QMI_UIM_
CARD_STATE_ABSENT to QMI_UIM_CARD_STATE_PRESENT"

7: date=2023-04-28 time=17:27:12 eventtime=1682728032589776580 tz="-0700"
logid="0100046513" type="event" subtype="system" level="information" vd="root"
logdesc="LTE modem data link connection event" msg="LTE modem data link changed from
QMI_WDS_CONNECTION_STATUS_CONNECTED to QMI_WDS_CONNECTION_STATUS_DISCONNECTED"

8: date=2023-04-28 time=17:27:11 eventtime=1682728031245682560 tz="-0700"
logid="0100046512" type="event" subtype="system" level="information" vd="root"
logdesc="LTE modem SIM card state event" msg="LTE modem SIM card change from QMI_UIM_
CARD_STATE_PRESENT to QMI_UIM_CARD_STATE_ABSENT"
```

To enable automatic SIM card switching by connection state:

1. Enable automatic SIM card switching by connection state:

```
config system lte-modem
    config sim-switch
        set by-connection-state enable
        set modem-disconnection-time 30
        set sim-switch-log-alert-interval 15
        set sim-switch-log-alert-threshold 5
    end
end
```

With this configuration, the second SIM card becomes active when the modem cannot establish a connection with the carrier through the active SIM card. For example, a FortiGate is in a room with poor signal quality. With this configuration, the SIM card switch is triggered after the modem is detected as disconnected for 30 seconds, and the following event log is generated:

```
56: date=2023-05-01 time=11:14:56 eventtime=1682964896356933480 tz="-0700"
logid="0100046519" type="event" subtype="system" level="notice" vd="root" logdesc="LTE
modem active SIM card switched: modem disconnection detected" msg="LTE modem active SIM
card slot changed to 2, due to modem connection down."
```

```
66: date=2023-05-01 time=11:14:13 eventtime=1682964852964869400 tz="-0700"
logid="0100046519" type="event" subtype="system" level="notice" vd="root" logdesc="LTE
modem active SIM card switched: modem disconnection detected" msg="LTE modem active SIM
card slot changed to 1, due to modem connection down."
```

When poor signal quality causes SIM cards to frequently switch back and forth, and the flapping rate occurs more than five times within the configured 15 minute time period, an event log is triggered to record the flapping severity:

```
65: date=2023-05-01 time=11:14:13 eventtime=1682964853083194400 tz="-0700"
logid="0100046521" type="event" subtype="system" level="warning" vd="root" logdesc="LTE
modem active SIM card slot flipped back and forth in short time" msg="LTE modem switched
SIM slot 8 times in last 15 minutes, which is greater than 5 times threshold."
```

To enable automatic SIM card switching based on link monitor:

1. Enable automatic SIM card switching by link monitor, and specify the link monitor:

```
config system lte-modem
    config sim-switch
        set by-link-monitor enable
        set link-monitor "modem"
        set sim-switch-log-alert-interval 15
        set sim-switch-log-alert-threshold 5
    end
    config system link-monitor
        edit "modem"
            set srcintf "wwan"
            set server "8.8.8.8"
            set interval 1000
            set probe-timeout 100
            set failtime 3
            set recoverytime 8
        next
    end
```

With this configuration, the second SIM card becomes active when the link monitor detects the active SIM card exceeds the SLA.

2. Check the link monitor status. In this example, the link monitor status is dead:

```
# diagnose system link-monitor status modem
```

```
Link Monitor: modem, Status: dead, Server num(1), cfg_version=7 HA state: local(dead),
shared(dead)
Flags=0x9 init log_downgateway, Create time: Fri Apr 28 16:34:56 2023
Source interface: wwan (19)
VRF: 0
Interval: 1000 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
    Peer: 8.8.8.8(8.8.8.8)
        Source IP(10.192.195.164)
```

```

Route: 10.192.195.164->8.8.8.8/32, gwy(10.192.195.165)
protocol: ping, state: dead
    Packet lost: 11.667%
    MOS: 4.353
    Number of out-of-sequence packets: 0
    Recovery times(5/8) Fail Times(1/3)
    Packet sent: 60, received: 56, Sequence(sent/rcvd/exp): 61/61/62

```

The following event log is generated when the link-monitor status is dead:

```

15: date=2023-04-28 time=16:31:38 eventtime=1682724697936494139 tz="-0700"
logid="0100046520" type="event" subtype="system" level="notice" vd="root" logdesc="LTE
modem active SIM card switched: link monitor probe failure detected" msg="LTE modem
active SIM card slot changed to 2, due to link monitor probe failures."

19: date=2023-04-28 time=16:31:13 eventtime=1682724673152506599 tz="-0700"
logid="0100022932" type="event" subtype="system" level="warning" vd="root" logdesc="Link
monitor status warning" name="modem" interface="wwan" probepROTO="ping" msg="Link
Monitor changed state from alive to dead, protocol: ping."

```

LLDP reception

Device detection can scan LLDP as a source for device identification, but the FortiGate does not read or store the full information. Enabling LLDP reception allows the FortiGate to receive and store LLDP messages, learn about active neighbors, and makes the LLDP information available via the CLI, REST API, and SNMP.

You need to enable device detection (device-identification) at the interface level, and then `lldp-reception` can be enabled on three levels: globally, per VDOM, or per interface.

To configure device identification on an interface:

```

config system interface
    edit <port>
        set device-identification enable
    next
end

```

To configure LLDP reception globally:

```

config system global
    set lldp-reception enable
end

```

To configure LLDP reception per VDOM:

```

config system setting
    set lldp-reception enable
end

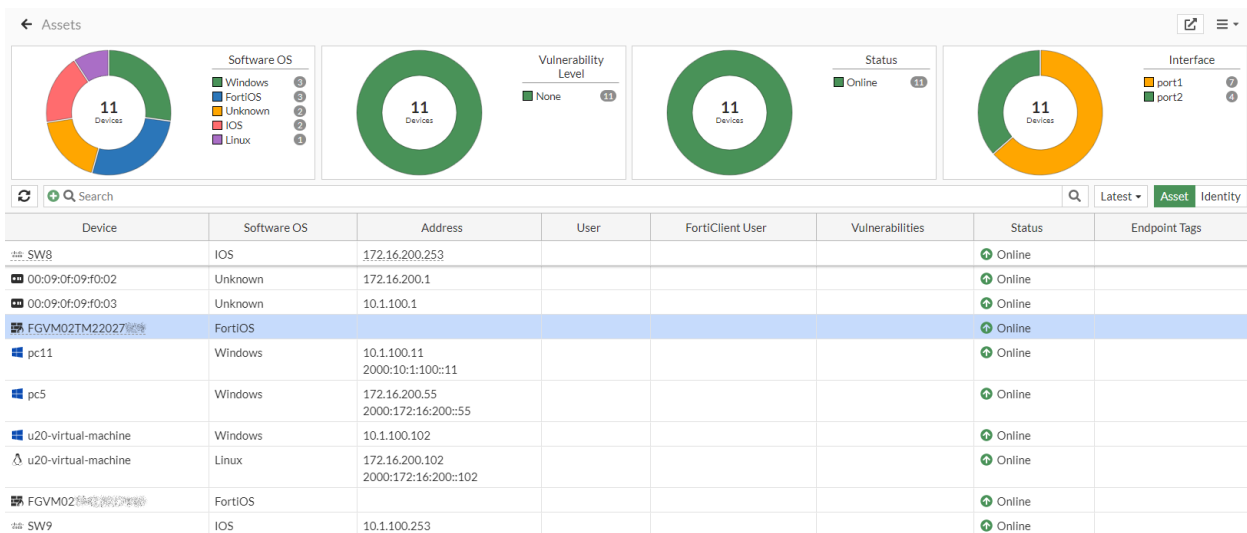

```

To configure LLDP reception per interface:

```
config system interface
  edit <port>
    set lldp-reception enable
  next
end
```

To view the LLDP information in the GUI:

1. Go to *Dashboard > Assets & Identities*.
2. Expand the *Assets* widget to full screen.

To view the received LLDP information in the CLI:

```
# diagnose user device list
hosts
vd root/0 00:0c:29:1c:03:ca gen 4320 req 0
  created 515971s gen 31 seen 28s port1 gen 12
  hardware vendor 'Fortinet' src lldp id 4120 weight 255
  type 'Router' src lldp id 4120 weight 255
  family 'FortiGate' src lldp id 4120 weight 255
  os 'FortiOS' src lldp id 4120 weight 255
  hardware version 'VM64' src lldp id 4120 weight 255
  software version '7.4.0 Build 2360' src lldp id 4120 weight 255
  host 'FGVM02TM22027XXX' src lldp
```

To view additional information about LLDP neighbors and ports:

```
# diagnose lldprx neighbor {summary | details | clear}
# diagnose lldprx port {details | summary | neighbor | filter}
# diagnose lldprx port neighbor {summary | details}
```

Note that the port index in the output corresponds to the port index from the following command:

```
# diagnose netlink interface list port2 port3 | grep index
if=port2 family=00 type=1 index=4 mtu=1500 link=0 master=0
if=port3 family=00 type=1 index=5 mtu=1500 link=0 master=0
```

To view the received LLDP information in the REST API:

```

```

Virtual routing and forwarding

Virtual Routing and Forwarding (VRF) is used to divide the FortiGate's routing functionality (layer 3), including interfaces, routes, and forwarding tables, into separate units. Packets are only forwarded between interfaces that have the same VRF.

VDOMs divide the FortiGate into two or more complete and independent virtual units that include all FortiGate functions. VDOMs can be used for routing segmentation, but that should not be the only reason to implement them when a less complex solution (VRFs) can be used. VDOMs also support administration boundaries, but VRFs do not.

Up to 252 VRFs can be configured per VDOM for any device, but only ten VDOMs can be configured by default on a FortiGate (more VDOMs can be configured on larger devices with additional licenses).

- [Implementing VRF on page 553](#)
- [VRF routing support on page 554](#)
- [Route leaking between VRFs with BGP on page 560](#)
- [Route leaking between multiple VRFs on page 562](#)
- [VRF with IPv6 on page 573](#)
- [IBGP and EBGP support in VRF on page 576](#)
- [Support cross-VRF local-in and local-out traffic for local services on page 579](#)

Implementing VRF

VRFs are always enabled and, by default, all routing is done in VRF 0. To use additional VRFs, assign a VRF ID to an interface. All routes relating to that interface are isolated to that VRF specific routing table. Interfaces in one VRF cannot reach interfaces in a different VRF.

If some traffic does have to pass between VRFs, route leaking can be used. See [Route leaking between VRFs with BGP on page 560](#).

Enable *Advanced Routing* in *System > Feature Visibility* to configure VRFs.

To configure a VRF ID on an interface in the GUI:

1. Go to *Network > Interfaces* and click *Create New > Interface*.
2. Enter a value in the VRF ID field.
3. Configure the other settings as needed.

4. Click OK.
5. To add the VRF column in the interface table, click the gear icon, select *VRF*, and click *Apply*.

To configure a VRF ID on an interface in the CLI:

```
config system interface
  edit interface42
    ...
    set vrf 14
  next
end
```

VRF routing support

VRF supports static routing, OSPF, and BGP. Other routing protocols require using VDOMs.

BGP

In this example, BGP is used to update the VRF that it is neighbors with.

The hub is configured with two neighbors connected to two interfaces. The branches are configured to match the hub, with branch networks configured to redistribute into BGP.

Policies must be created on the hub and branches to allow traffic between them.

To configure the hub:

```
config router bgp
  set as 65000
  config neighbor
    edit "10.101.101.2"
      set soft-reconfiguration enable
      set interface "port2"
      set remote-as 65101
      set update-source "port2"
    next
    edit "10.102.102.2"
      set soft-reconfiguration enable
      set interface "port3"
      set remote-as 65102
      set update-source "port3"
    next
  end
end
```

To configure branch 101:

```
config router bgp
  set as 65101
  config neighbor
    edit "10.101.101.1"
      set soft-reconfiguration enable
      set interface "port2"
      set remote-as 65000
      set update-source "port2"
    next
  end
  config redistribute connected
    set status enable
  end
end
```

To configure branch 102:

```
config router bgp
  set as 65102
  config neighbor
    edit "10.102.102.1"
      set soft-reconfiguration enable
      set interface "port2"
      set remote-as 65000
```

```

        set update-source "port2"
    next
end
config redistribute connected
    set status enable
end
end

```

To verify the BGP neighbors and check the routing table on the hub:

```

# get router info bgp summary
BGP router identifier 192.168.0.1, local AS number 65000
BGP table version is 2
2 BGP AS-PATH entries
0 BGP community entries

```

Neighbor		V	AS		MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/Pf
10.101.101.2	4	65101		4		4		2		0	0
10.102.102.2	4	65102		3		3		1		0	0

Total number of neighbors 2

```

# get router info routing-table all
Routing table for VRF=0
Codes (..)
S* 0.0.0.0/0 [10/0] via 192.168.0.254, port1
C 10.101.101.0/24 is directly connected, port2
C 10.102.102.0/24 is directly connected, port3
C 192.168.0.0/24 is directly connected, port1
B 192.168.101.0/24 [20/0] via 10.101.101.2, port2, 00:01:25
B 192.168.102.0/24 [20/0] via 10.102.102.2, port3, 00:00:50

```

To configure VRF on the hub:

1. Put the interfaces into VRF:

```

config system interface
    edit port2
        set vrf 10
    next
    edit port3
        set vrf 20
    next
end

```

2. Restart the router to reconstruct the routing tables:

```

# execute router restart

```

3. Check the routing tables:

```

# get router info routing-table all
Routing table for VRF=0
Codes (..)
S* 0.0.0.0/0 [10/0] via 192.168.0.254, port1
C 192.168.0.0/24 is directly connected, port1

Routing table for VRF=10

```

```
C    10.101.101.0/24 is directly connected, port2
B    192.168.101.0/24 [20/0] via 10.101.101.2, port2, 00:02:25
```

Routing table for **VRF=20**

```
C    10.102.102.0/24 is directly connected, port3
B    192.168.102.0/24 [20/0] via 10.102.102.2, port2, 00:01:50
```

4. Check the BGP summary:

```
# get router info bgp summary
```

```
VRF 10 BGP router identifier 10.101.101.1, local AS number 65000
BGP table version is 1
2 BGP AS-PATH entries
0 BGP community entries
```

Neighbor		V	AS		MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State
10.101.101.2	4	65101		4		4		2		0	0

```
Total number of neighbors 1
```

```
VRF 10 BGP router identifier 10.101.101.1, local AS number 65000
BGP table version is 1
2 BGP AS-PATH entries
0 BGP community entries
```

Neighbor		V	AS		MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State
10.102.102.2	4	65102		3		3		1		0	0

```
Total number of neighbors 1
```

OSPF

OSPF routes in VRFs work the same as BGP: the interface that OSPF is using is added to the VRF.

To configure the hub:

1. Configure OSPF:

```
config router ospf
  set router-id 1.1.1.1
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit Branch101
      set interface "port2"
      set dead-interval 40
      set hello-interval 10
    next
    edit Branch102
      set dead-interval 40
      set hello-interval 10
    next
  end
```

```
    config network
        edit 0
            set prefix 10.101.101.0 255.255.255.0
        next
        edit 0
            set prefix 10.102.102.0 255.255.255.0
        next
        edit 0
            set prefix 192.168.1.0 255.255.255.0
        next
    end
end
```

2. Put the interfaces into VRF:

```
config system interface
    edit port2
        set vrf 10
    next
    edit port3
        set vrf 20
    next
end
```

To configure branch 101:

```
config router ospf
    set router-id 101.101.101.101
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit HUB
            set interface port2
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 0
            set prefix 10.101.101.0 255.255.255.0
        next
        edit 0
            set prefix 192.168.101.0 255.255.255.0
        next
    end
end
```

To check the routing table and OSPF summary:

```
# get router info routing-table ospf
# get router info ospf interface
```

Static route

Static routes in VRFs work the same as BGP and OSPF because the interface that the static route is using is added to the VRF.

To add a VRF ID in a static route in the GUI:

1. Configure the interface:
 - a. Go to *Network > Interfaces*.
 - b. Click *Create New > Interface* or *Edit* an existing interface.
 - c. Enter a value in the *VRF ID* field.
 - d. Configure the other settings as needed.
 - e. Click *OK*.
2. Add a static route to VRF. For example, using blackhole:
 - a. Go to *Network > Static Routes*.
 - b. Click *Create New* and select the type of static route.
 - c. Enter a *Subnet*.
 - d. In the *Interface* field, select *Blackhole*.
 - e. In the *VRF ID* field, enter the ID created in step one.
 - f. Click *OK*.

To add a VRF ID in a static route in the CLI:

1. Configure the interface:

```
config system interface
  edit port2
    set vrf 10
  next
end
```
2. Add a static route to the VRF. For example, using blackhole:

```
config router static
  edit 3
    set dst 0.0.0.0/0
    set blackhole enable
    set vrf 10
  next
end
```

A static route can also be added to the VRF when using an IPsec interface by enabling VPN ID with IPsec encapsulation. See [SD-WAN segmentation over a single overlay on page 997](#) for more information.

To add a static route to the VRF when using IPsec:

```
config vpn ipsec phase1-interface
  edit "vpn1"
    set interface "port2"
    set auto-discovery-receiver enable
    set encapsulation vpn-id-ipip
    set remote-gw 1.1.101.1
```

```

        set psksecret *****
    next
end
config router static
    edit 1
        set dst 10.32.0.0 255.224.0.0
        set device "vpn1"
        set vrf 10
    next
end

```

To check the routing table:

```
# get router info routing-table static
```

Route leaking between VRFs with BGP

Route leaking allows you to configure communication between VRFs. If route leaking is not configured, then the VRFs are isolated. This example shows route leaking with BGP using virtual inter-VDOM links.

In this example, a hub FortiGate forms BGP neighbors with two branches. It learns the networks 192.168.101.0/24 and 192.168.102.0/24 from the neighbors and separates them into VRF 10 and VRF 20.

To leak the learned routes to each other, an inter-VDOM link (IVL) is formed. An IVL normally bridges two VDOMs, but in this case the links reside on the same VDOM and are used to bridge the two VRFs. NPU links could also be used on models that support it to deliver better performance.

VRF 10 has a leaked route to 192.168.102.0/24 on IVL *link-10-20-0*, and VRF 20 has a leaked route to 192.168.101.0/24 on IVL *link-10-20-1*,

To configure route leaking:

1. Allow interface subnets to use overlapping IP addresses:

```

config system settings
    set allow-subnet-overlap enable
end

```

2. Configure the inter-VDOM links:

```

config system vdom-link
    edit link-10-20-
        next
    end

```

3. Configure the interface settings:

```
config system interface
  edit link-10-20-0
    set vdom "root"
    set vrf 10
    set ip 10.1.1.1/30
  next
  edit link-10-20-1
    set vdom "root"
    set vrf 20
    set ip 10.1.1.2/30
  next
end
```

4. Create the prefix lists:

These objects define the subnet and mask that are leaked.

```
config router prefix-list
  edit VRF10_Route
    config rule
      edit 1
        set prefix 192.168.101.0 255.255.255.0
      next
    end
  next
  edit VRF20_Route
    config rule
      edit 1
        set prefix 192.168.102.0 255.255.255.0
      next
    end
  next
end
```

5. Create the route map:

The route map can be used to group one or more prefix lists.

```
config router route-map
  edit "Leak_from_VRF10_to_VRF20"
    config rule
      edit 1
        set match-ip-address "VRF10_Route"
      next
    end
  next
  edit "Leak_from_VRF20_to_VRF10"
    config rule
      edit 1
        set match-ip-address "VRF20_Route"
      next
    end
  next
end
```

6. Configure the VRF leak in BGP, specifying a source VRF, destination VRF, and the route map to use:

```
config router bgp
  config vrf
```

```

edit "10"
  config leak-target
    edit "20"
      set route-map "Leak_from_VRF10_to_VRF20"
      set interface "link-10-20-0"
    next
  end
next
edit "20"
  config leak-target
    edit "10"
      set route-map "Leak_from_VRF20_to_VRF10"
      set interface "link-10-20-1"
    next
  end
next
end
end

```

7. Create policies to allow traffic between the VRFs.

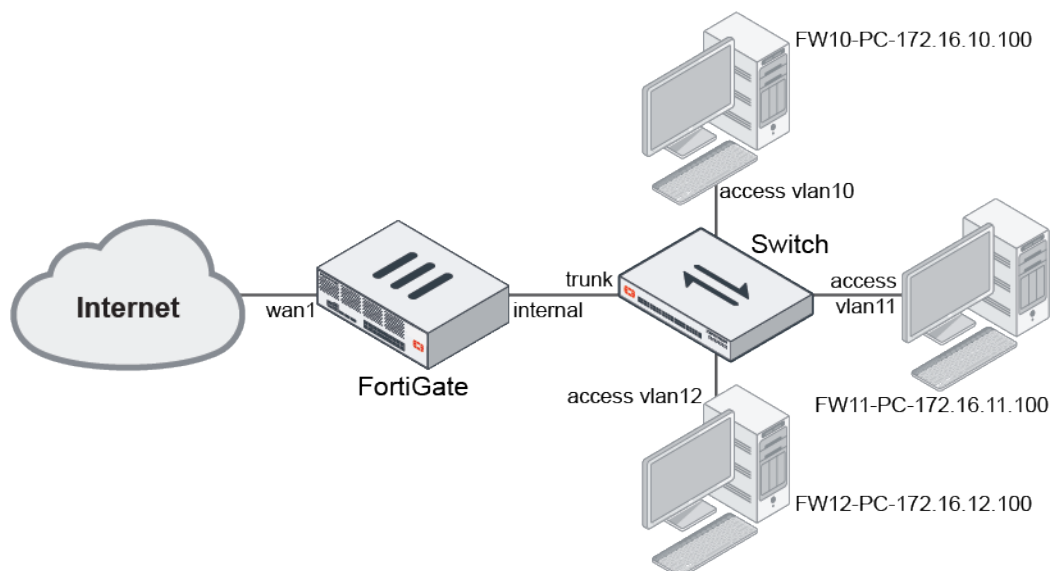

Without a policy permitting traffic on the route between the VRFs, the VRFs are still isolated.

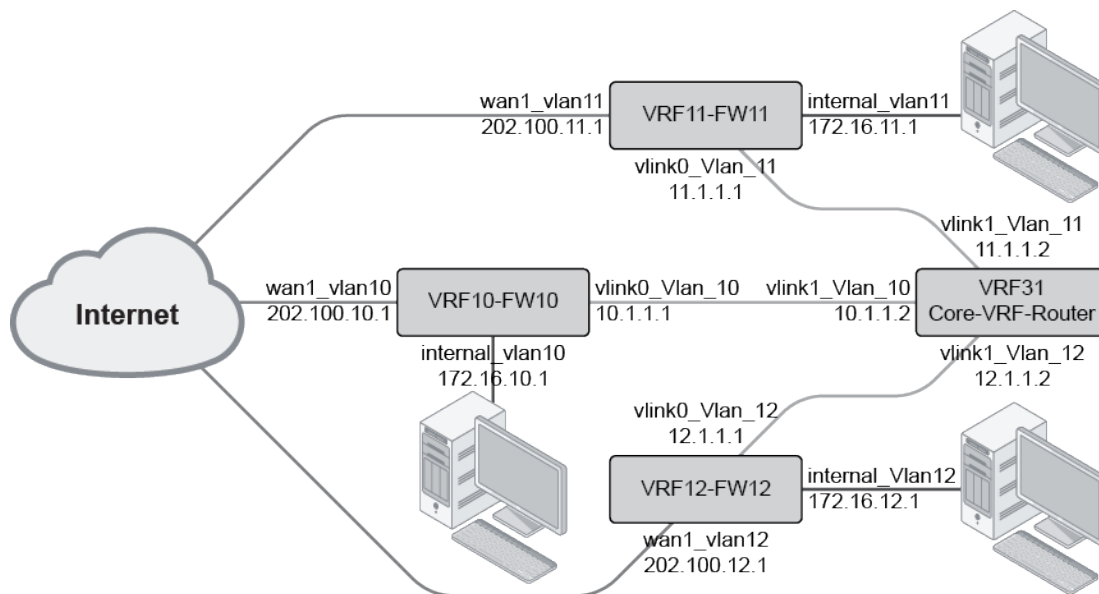

Route leaking between multiple VRFs

In this example, routing leaking between three VRFs in a star topology is configured. This allows the solution to be scaled to more VRFs without building full mesh, one-to-one connections between each pair of VRFs. VLAN subinterfaces are created on VDOM links to connect each VRF to the central VRF, allowing routes to be leaked from a VRF to the central VRF, and then to the other VRFs. Static routes are used for route leaking in this example.

For instructions on creating route leaking between two VRFs, see [Route leaking between VRFs with BGP on page 560](#).

Physical topology:

Logical topology:

In this example, a specific route is leaked from each of the VRFs to each of the other VRFs. VLAN subinterfaces are created based on VDOM links to connect each VRF to the core VRF router.

Multi VDOM mode is enabled so that NP VDOM links can be used. The setup could be configured without enabling multi VDOM mode by manually creating non-NP VDOM links, but this is not recommended as the links are not offloaded to the NPU.

After VDOMs are enabled, all of the configuration is done in the *root* VDOM.

To configure the FortiGate:**1. Enable multi VDOM mode:**

```
config system global
    set vdom-mode multi-vdom
end
```

If the FortiGate has an NP, the VDOM links will be created:

```
# show system interface
config system interface
    ...
    edit "npu0_vlink0"
        set vdom "root"
        set type physical
    next
    edit "npu0_vlink1"
        set vdom "root"
        set type physical
    next
    ...
end
```

If multi VDOM mode is not used, the VDOM links can be manually created:

```
config system vdom-link
  edit <name of vmlink>
  next
end
```

2. Allow interface subnets to use overlapping IP addresses:

```
config vdom
  edit root
    config system settings
      set allow-subnet-overlap enable
    end
```

3. Configure the inter-connecting VLAN subinterfaces between VRF based on VDOM-LINK:

```
config system interface
  edit "vlink0_vlan_10"
    set vdom "root"
    set vrf 10
    set ip 10.1.1.1 255.255.255.252
    set allowaccess ping https ssh http
    set alias "vlink0_vlan_10"
    set role lan
    set interface "npu0_vlink0"
    set vlanid 10
  next
  edit "vlink1_vlan_10"
    set vdom "root"
    set vrf 31
    set ip 10.1.1.2 255.255.255.252
    set allowaccess ping https ssh http
    set alias "vlink1_vlan_10"
    set role lan
    set interface "npu0_vlink1"
    set vlanid 10
  next
  edit "vlink0_vlan_11"
    set vdom "root"
    set vrf 11
    set ip 11.1.1.1 255.255.255.252
    set allowaccess ping https ssh http
    set alias "vlink0_vlan_11"
    set role lan
    set interface "npu0_vlink0"
    set vlanid 11
  next
  edit "vlink1_vlan_11"
    set vdom "root"
    set vrf 31
    set ip 11.1.1.2 255.255.255.252
    set allowaccess ping https ssh http
    set alias "vlink1_vlan_11"
    set role lan
    set interface "npu0_vlink1"
    set vlanid 11
  next
  edit "vlink0_vlan_12"
```

```

        set vdom "root"
        set vrf 12
        set ip 12.1.1.1 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink0_vlan_12"
        set role lan
        set interface "np0_vlink0"
        set vlanid 12
    next
    edit "vlink1_vlan_12"
        set vdom "root"
        set vrf 31
        set ip 12.1.1.2 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink1_vlan_12"
        set role lan
        set interface "np0_vlink1"
        set vlanid 12
    next
end

```

4. Configure a zone to allow intrazone traffic between VLANs in the central VRF:

```

config system zone
    edit "Core-VRF-Router"
        set intrazone allow
        set interface "vlink1_vlan_10" "vlink1_vlan_11" "vlink1_vlan_12"
    next
end

```

5. Add allow policies for the VRF31 core router:

```

config firewall policy
    edit 0
        set name "any_to_core_vrf31"
        set srcintf "any"
        set dstintf "Core-VRF-Router"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 0
        set name "core_vrf31_to_any"
        set srcintf "Core-VRF-Router"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
end

```

6. Configure VRF10, VRF11, and VRF12 on the Internal and WAN VLAN sub-interfaces:

```
config system interface
  edit "Internal_VRF10"
    set vdom "root"
    set vrf 10
    set ip 172.16.10.1 255.255.255.0
    set allowaccess ping https ssh http
    set alias "Internal_VRF10"
    set role lan
    set interface "internal"
    set vlanid 10
  next
  edit "Internal_VRF11"
    set vdom "root"
    set vrf 11
    set ip 172.16.11.1 255.255.255.0
    set allowaccess ping https ssh http
    set alias "Internal_VRF11"
    set role lan
    set interface "internal"
    set vlanid 11
  next
  edit "Internal_VRF12"
    set vdom "root"
    set vrf 12
    set ip 172.16.12.1 255.255.255.0
    set allowaccess ping https ssh http
    set alias "Internal_VRF12"
    set role lan
    set interface "internal"
    set vlanid 12
  next
  edit "wan1_VRF10"
    set vdom "root"
    set vrf 10
    set ip 202.100.10.1 255.255.255.0
    set allowaccess ping
    set alias "wan1_VRF10"
    set role wan
    set interface "wan1"
    set vlanid 10
  next
  edit "wan1_VRF11"
    set vdom "root"
    set vrf 11
    set ip 202.100.11.1 255.255.255.0
    set allowaccess ping
    set alias "wan1_VRF11"
    set role wan
    set interface "wan1"
    set vlanid 11
  next
  edit "wan1_VRF12"
    set vdom "root"
    set vrf 12
    set ip 202.100.12.1 255.255.255.0
    set allowaccess ping
```

```
        set alias "wan1_VRF12"
        set role wan
        set interface "wan1"
        set vlanid 12
    next
end
```

7. Configure static routing and route leaking between each VRF and Core-VRF-Router:

```
config router static
    edit 1
        set dst 172.16.10.0 255.255.255.0
        set gateway 10.1.1.1
        set device "vlink1_Vlan_10"
        set comment "VRF31_Core_Router"
    next
    edit 2
        set dst 172.16.11.0 255.255.255.0
        set gateway 11.1.1.1
        set device "vlink1_Vlan_11"
        set comment "VRF31_Core_Router"
    next
    edit 3
        set dst 172.16.12.0 255.255.255.0
        set gateway 12.1.1.1
        set device "vlink1_Vlan_12"
        set comment "VRF31_Core_Router"
    next
    edit 4
        set dst 172.16.11.0 255.255.255.0
        set gateway 10.1.1.2
        set device "vlink0_Vlan_10"
        set comment "VRF10_Route_Leaking"
    next
    edit 5
        set dst 172.16.12.0 255.255.255.0
        set gateway 10.1.1.2
        set device "vlink0_Vlan_10"
        set comment "VRF10_Route_Leaking"
    next
    edit 6
        set dst 172.16.10.0 255.255.255.0
        set gateway 11.1.1.2
        set device "vlink0_Vlan_11"
        set comment "VRF11_Route_Leaking"
    next
    edit 7
        set dst 172.16.12.0 255.255.255.0
        set gateway 11.1.1.2
        set device "vlink0_Vlan_11"
        set comment "VRF11_Route_Leaking"
    next
    edit 8
        set dst 172.16.10.0 255.255.255.0
        set gateway 12.1.1.2
        set device "vlink0_Vlan_12"
```

```

        set comment "VRF12_Route_Leaking"
    next
    edit 9
        set dst 172.16.11.0 255.255.255.0
        set gateway 12.1.1.2
        set device "vlink0_Vlan_12"
        set comment "VRF12_Route_Leaking"
    next
    edit 10
        set gateway 202.100.10.254
        set device "wan1_VRF10"
        set comment "VRF10_Default_Route"
    next
    edit 11
        set gateway 202.100.11.254
        set device "wan1_VRF11"
        set comment "VRF11_Default_Route"
    next
    edit 12
        set gateway 202.100.12.254
        set device "wan1_VRF12"
        set comment "VRF12_Default_Route"
    next
end

```

In the GUI, go to **Network > Static Routes** to view the static routes:

+ Create New	Edit	Clone	Delete	<input type="text" value="Search"/>	Q
Destination	Gateway IP	Interface	Status	Comments	
IPv4					
172.16.10.0/24	10.1.1.1	vlink1_Vlan_10 (vlink1_Vlan_10)	Enabled	VRF31_Core_Router	
172.16.11.0/24	11.1.1.1	vlink1_Vlan_11 (vlink1_Vlan_11)	Enabled	VRF31_Core_Router	
172.16.12.0/24	12.1.1.1	vlink1_Vlan_12 (vlink1_Vlan_12)	Enabled	VRF31_Core_Router	
172.16.11.0/24	10.1.1.2	vlink0_Vlan_10 (vlink0_Vlan_10)	Enabled	VRF10_Route_Leaking	
172.16.12.0/24	10.1.1.2	vlink0_Vlan_10 (vlink0_Vlan_10)	Enabled	VRF10_Route_Leaking	
172.16.10.0/24	11.1.1.2	vlink0_Vlan_11 (vlink0_Vlan_11)	Enabled	VRF11_Route_Leaking	
172.16.12.0/24	11.1.1.2	vlink0_Vlan_11 (vlink0_Vlan_11)	Enabled	VRF11_Route_Leaking

172.16.11.0/24	12.1.1.2	vlink0_Vlan_12 (vlink0_Vlan_12)	Enabled	VRF12_Route_Leaking	
0.0.0.0/0	202.100.10.254	wan1_VRF10 (wan1_VRF10)	Enabled	VRF10_Default_Route	
0.0.0.0/0	202.100.11.254	wan1_VRF11 (wan1_VRF11)	Enabled	VRF11_Default_Route	
0.0.0.0/0	202.100.12.254	wan1_VRF12 (wan1_VRF12)	Enabled	VRF12_Default_Route	

8. Configure firewall policies for VRF10, VRF11, and VRF12

```

config firewall policy
    edit 6
        set name "VRF10_to_Internet_Policy"
        set srcintf "Internal_VRF10"
        set dstintf "wan1_VRF10"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set nat enable
    next
    edit 7

```

```
        set name "VRF10_to_VRF_Leaking_Route"
        set srcintf "Internal_VRF10"
        set dstintf "vlink0_Vlan_10"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 8
        set name "VRF_Leaking_Route_to_VRF10"
        set srcintf "vlink0_Vlan_10"
        set dstintf "Internal_VRF10"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 9
        set name "VRF11_to_Internet_Policy"
        set srcintf "Internal_VRF11"
        set dstintf "wan1_VRF11"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set nat enable
    next
    edit 10
        set name "VRF11_to_VRF_Leaking_Route"
        set srcintf "Internal_VRF11"
        set dstintf "vlink0_Vlan_11"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 11
        set name "VRF_Leaking_Route_to_VRF11"
        set srcintf "vlink0_Vlan_11"
        set dstintf "Internal_VRF11"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
```

```

edit 12
    set name "VRF12_to_Internet_Policy"
    set srcintf "Internal_VRF12"
    set dstintf "wan1_VRF12"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
    set nat enable
next
edit 13
    set name "VRF12_to_VRF_Leaking_Route"
    set uuid 92bccf8e-b27b-51eb-3c56-6d5259af6299
    set srcintf "Internal_VRF12"
    set dstintf "vlink0_Vlan_12"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
next
edit 14
    set name "VRF_Leaking_Route_to_VRF12"
    set srcintf "vlink0_Vlan_12"
    set dstintf "Internal_VRF12"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
next
end

```

In the GUI, go to *Policy & Objects > Firewall Policy* to view the policies.

To check the results:

1. On the FortiGate, check the routing table to see each VRF:

```

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

```

VRF with IPv6

IPv6 routes support VRF. Static, connected, OSPF, and BGP routes can be isolated in different VRFs. BGP IPv6 routes can be leaked from one VRF to another.

```
config router bgp
  config vrf6
    edit <origin vrf-id>
      config leak-target
        edit <target vrf-id>
          set route-map <route-map>
          set interface <interface>
        next
      end
    next
  end
end
```

The origin or target VRF ID is an integer value from 0 - 31.

```
config router static6
  edit <id>
    set vrf <vrf-id>
  next
end
```

Using a VRF leak on BGP

In this example, the route 2000:5:5:5::/64 learned from Router 1 is leaked to VRF 20 through the interface vlan552. Conversely, the route 2009:3:3:3::/64 learned from Router 2 is leaked to VRF 10 through interface vlan55.

To configure VRF leaking in BGP:

1. Configure the BGP neighbors:

```
config router bgp
  set as 65412
  config neighbor
```

```

        edit "2000:10:100:1::1"
            set activate disable
            set remote-as 20
            set update-source "R150"
        next
        edit "2000:10:100:1::5"
            set activate disable
            set soft-reconfiguration enable
            set interface "R160"
            set remote-as 20
        next
    end
end

```

2. Configure the VLAN interfaces:

```

config system interface
    edit "vlan55"
        set vdom "root"
        set vrf 10
        set ip 55.1.1.1 255.255.255.0
        set device-identification enable
        set role lan
        set snmp-index 51
        config ipv6
            set ip6-address 2000:55::1/64
        end
        set interface "np0_vlink0"
        set vlanid 55
    next
    edit "vlan552"
        set vdom "root"
        set vrf 20
        set ip 55.1.1.2 255.255.255.0
        set device-identification enable
        set role lan
        set snmp-index 53
        config ipv6
            set ip6-address 2000:55::2/64
        end
        set interface "np0_vlink1"
        set vlanid 55
    next
end

```

3. Configure the IPv6 prefixes:

```

config router prefix-list6
    edit "1"
        config rule
            edit 1
                set prefix6 2000:5:5:5::/64
                unset ge
                unset le
            next
        end
    next
end

```

```
        edit "2"
            config rule
                edit 1
                    set prefix6 2009:3:3:3::/64
                    unset ge
                    unset le
                next
            end
        next
    end
```

4. Configure the route maps:

```
config router route-map
    edit "from106"
        config rule
            edit 1
                set match-ip6-address "1"
            next
        end
    next
    edit "from206"
        config rule
            edit 1
                set match-ip6-address "2"
            next
        end
    next
end
```

5. Configure the IPv6 route leaking (leak route 2000:5:5:5::/64 learned from Router 1 to VRF 20, then leak route 2009:3:3:3::/64 learned from Router 2 to VRF 10):

```
config router bgp
    config vrf6
        edit "10"
            config leak-target
                edit "20"
                    set route-map "from106"
                    set interface "vlan55"
                next
            end
        next
        edit "20"
            config leak-target
                edit "10"
                    set route-map "from206"
                    set interface "vlan552"
                next
            end
        next
    end
end
```

To verify the VRF leaking:**1. Check the routing table before the leak:**

```
# get router info6 routing-table bgp
Routing table for VRF=10
B      2000:5:5:5::/64 [20/0] via fe00::2000:0000:0000:00, R150, 00:19:45

Routing table for VRF=20
B      2008:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:18:49
B      2009:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:18:49
```

2. Check the routing table after the leak:

```
# get router info6 routing-table bgp
Routing table for VRF=10
B      2000:5:5:5::/64 [20/0] via fe00::2000:0000:0000:00, R150, 00:25:45
B      2009:3:3:3::/64 [20/0] via fe80::10:0000:0000:4245, vlan55, 00:00:17

Routing table for VRF=20
B      2000:5:5:5::/64 [20/0] via fe80::10:0000:0000:4244, vlan552, 00:00:16
B      2008:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:24:49
B      2009:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:24:49
```

Using VRF on a static route

In this example, a VRF is defined on static route 22 so that it will only appear in the VRF 20 routing table.

To configure the VRF on the static route:

```
config router static6
  edit 22
    set dst 2010:2:2:2::/64
    set blackhole enable
    set vrf 20
  next
end
```

IBGP and EBGp support in VRF

Support is included for internal and external border gateway protocols (IBGP and EBGp) in virtual routing and forwarding (VRF).

FortiGate can establish neighbor connections with other FortiGates or routers, and the learned routes are put into different VRF tables according to the neighbor's settings.

This example uses the following topology:

- BGP routes learned from the Router1 neighbor are put into vrf10.
- BGP routes learned from the Router2 neighbor are put into vrf20.

To configure this example:

```

config system interface
    edit port1
        set vrf 10
    next
    edit port2
        set vrf 20
    next
end

config router bgp
    config neighbor
        edit "192.168.1.1"
            set update-source port1
        next
        edit "192.168.2.1"
            set interface port2
        next
    end
end

```

Results

Using the above topology:

- Both Router1 and Router2 establish OSPF and BGP neighbor with the FortiGate.
- Router1 advertises 10.10.1.0/24 into OSPF and 10.10.2.0/24 into BGP.
- Router2 advertises 20.20.1.0/24 into OSPF and 20.20.2.0/24 into BGP.

When port1 and port2 have not set VRF, all of the routing is in VRF=0:

```

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

```

```

Routing table for VRF=0
S*    0.0.0.0/0 [5/0] via 10.0.1.254, port9
C     10.0.1.0/24 is directly connected, port9
O     10.10.1.0/24 [110/10] via 192.168.1.1, port1, 00:18:31
B     10.10.2.0/24 [20/200] via 192.168.1.1, port1, 00:01:31
O     20.20.1.0/22 [110/10] via 192.168.2.1, port2, 00:19:05
B     20.20.2.0/24 [20/200] via 192.168.2.1, port2, 00:01:31
C     192.168.1.0/24 is directly connected, port1
C     192.168.2.0/24 is directly connected, port2

```

After VRF is set for BGP, BGP routes are added to the VRF tables along with OSPF and connected routes:

```

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
        O - OSPF, IA - OSPF inter area
        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
        E1 - OSPF external type 1, E2 - OSPF external type 2
        i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
        * - candidate default

```

```

Routing table for VRF=0
S*    0.0.0.0/0 [5/0] via 10.0.1.254, port9
C     10.0.1.0/24 is directly connected, port9

```

```

Routing table for VRF=10
O     10.10.1.0/24 [110/10] via 192.168.1.1, port1, 00:18:31
B     10.10.2.0/24 [20/200] via 192.168.1.1, port1, 00:01:31
C     192.168.1.0/24 is directly connected, port1

```

```

Routing table for VRF=20
O     20.20.1.0/22 [110/10] via 192.168.2.1, port2, 00:19:05
B     20.20.2.0/24 [20/200] via 192.168.2.1, port2, 00:01:31
C     192.168.2.0/24 is directly connected, port2

```

BGP neighbor groups

This feature is also supported in the BGP neighbor groups. For example:

```

config router bgp
  config neighbor-group
    edit "FGT"
      set update-source "port1"
    next
  end
  config neighbor-range
    edit 1
      set prefix 172.16.201.0 255.255.255.0
      set neighbor-group "FGT"
    next
  end
end

```

Note that the `set interface` command is not supported.

Support cross-VRF local-in and local-out traffic for local services

When local-out traffic such as SD-WAN health checks, SNMP, syslog, and so on are initiated from an interface on one VRF and then pass through interfaces on another VRF, the reply traffic will be successfully forwarded back to the original VRF.

VRF 0 is a special VRF. By default, all routing is done in VRF 0. So all routes in different VRFs, such as VRF 10 or VRF 20, will all be included in VRF 0. VRF 0 cannot be used in the cross-VRF case.

For local-in and local-out traffic, all routes relating to one VRF are isolated from other VRFs so interfaces in one VRF cannot reach interfaces in a different VRF, except for VRF 0.

Example

In this example, there is an NPU VDOM link that is configured on the root VDOM. Two VLANs, vrf10 and vrf20, are created on either ends of the NPU VDOM link, each belonging to a different VRF.

When pinged from the vrf10 interface in VRF 10 to the destination server 172.16.202.2, since there is a single static route for VRF 10 with a gateway of vrf20/10.32.70.2, traffic is sent to the next hop and subsequently routed through port12 to the server.

As seen in the sniffer trace, the ICMP replies are received on port12 in VRF 20, then pass through vrf20, and are ultimately forwarded back to vrf10 in VRF 10. The traffic flow demonstrates that local-out traffic sourced from one VRF passing through another VRF can return back to the original VRF.

To configure cross-VRF local-out traffic for local services:

1. Configure the interfaces:

```
config system interface
  edit "vrf10"
    set vdom "root"
    set vrf 10
    set ip 10.32.70.1 255.255.255.0
    set allowaccess ping
    set device-identification enable
    set role lan
    set snmp-index 35
    set interface "npv0_vlink0"
    set vlanid 22
  next
  edit "vrf20"
```

```

        set vdom "root"
        set vrf 20
        set ip 10.32.70.2 255.255.255.0
        set allowaccess ping
        set device-identification enable
        set role lan
        set snmp-index 36
        set interface "npu0_vlink1"
        set vlanid 22
    next
    edit "port12"
        set vdom "root"
        set vrf 20
        set ip 172.16.202.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet fgfm radius-acct probe-response
fabric ftm speed-test
    set type physical
    set alias "TO_FGT_D_port22"
    set snmp-index 14
    config ipv6
        set ip6-address 2003:172:16:202::1/64
        set ip6-allowaccess ping
    end
next
end

```

2. Configure the firewall policy:

```

config firewall policy
    edit 1
        set srcintf "vrf20"
        set dstintf "port12"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
    next
end

```

3. Configure the static route:

```

config router static
    edit 2
        set gateway 10.32.70.2
        set distance 3
        set device "vrf10"
    next
end

```

To test the configuration:

1. Execute a ping from the vrf10 interface in VRF 10 to the destination server (172.16.202.2):

```

# execute ping-options interface vrf10
# execute ping 172.16.202.2

```

```
PING 172.16.202.2 (172.16.202.2): 56 data bytes
64 bytes from 172.16.202.2: icmp_seq=0 ttl=254 time=0.1 ms
64 bytes from 172.16.202.2: icmp_seq=1 ttl=254 time=0.0 ms

--- 172.16.202.2 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max = 0.0/0.0/0.1 ms
```

2. Run a sniffer trace on 172.16.202.2 for ICMP:

```
# diagnose sniffer packet any "host 172.16.202.2 and icmp" 4
interfaces=[any]
filters=[host 172.16.202.2 and icmp]
3.393920 vrf10 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393922 npu0_vlink0 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393927 vrf20 in 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393943 port12 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393977 port12 in 172.16.202.2 -> 10.32.70.1: icmp: echo reply
3.393987 vrf20 out 172.16.202.2 -> 10.32.70.1: icmp: echo reply
3.393988 npu0_vlink1 out 172.16.202.2 -> 10.32.70.1: icmp: echo reply
3.393993 vrf10 in 172.16.202.2 -> 10.32.70.1: icmp: echo reply
4.393941 vrf10 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
4.393942 npu0_vlink0 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
4.393948 vrf20 in 10.32.70.1 -> 172.16.202.2: icmp: echo request
4.393957 port12 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
4.393980 port12 in 172.16.202.2 -> 10.32.70.1: icmp: echo reply
4.393987 vrf20 out 172.16.202.2 -> 10.32.70.1: icmp: echo reply
4.393987 npu0_vlink1 out 172.16.202.2 -> 10.32.70.1: icmp: echo reply
4.393994 vrf10 in 172.16.202.2 -> 10.32.70.1: icmp: echo reply
```

NetFlow

NetFlow allows you to collect IP network traffic statistics for an interface, and then export those statistics for analysis. NetFlow samplers, that sample every packet, are configured per interface. Full NetFlow is supported through the information maintained in the firewall session.

To configure NetFlow:

```
config system netflow
    set collector-ip <ip>
    set collector-port <port>
    set source-ip <ip>
    set active-flow-timeout <integer>
    set inactive-flow-timeout <integer>
    set template-tx-timeout <integer>
    set template-tx-counter <integer>
end
```

collector-ip <ip>	Collector IPv4 or IPv6 address.
collector-port <port>	NetFlow collector port number (0 - 65535).

source-ip <ip>	Source IPv4 or IPv6 address, for communication with the NetFlow agent.
active-flow-timeout <integer>	Timeout to report active flows, in minutes (1 - 60, default = 30).
inactive-flow-timeout <integer>	Timeout for periodic report of finished flows, in seconds (10 - 600, default = 15).
template-tx-timeout <integer>	Timeout for periodic template flowset transmission, in minutes (1 - 1440, default = 30).
template-tx-counter <integer>	Counter of flowset records, before resending a template flowset record (10 - 6000, default = 20).

To configure NetFlow in a specific VDOM:

```
config vdom
  edit <vdom>
    config system vdom-netflow
      set vdom-netflow enable
      set collector-ip <ip>
      set collector-port <port>
      set source-ip <ip>
    end
  next
end
```

To configure a NetFlow sampler on an interface:

```
config system interface
  edit <interface>
    set netflow-sampler {disable | tx | rx | both}
  next
end
```

disable	Disable the NetFlow protocol on this interface (default).
tx	Monitor transmitted traffic on this interface.
rx	Monitor received traffic on this interface.
both	Monitor transmitted/received traffic on this interface.

Verification and troubleshooting

If data are not seen on the NetFlow collector after it has been configured, use the following sniffer commands to verify if the FortiGate and the collector are communicating:

- By collector port:

```
# diagnose sniffer packet 'port <collector-port>' 6 0 a
```

- By collector IP address:

```
# diagnose sniffer packet 'host <collector-ip>' 6 0 a
```

NetFlow uses the sflow daemon. The current NetFlow configuration can be viewed using test level 3 or 4:

```
# diagnose test application sflowd 3
# diagnose test application sflowd 4
Netflow Cache Stats:
vdoms=1 Collectors=1 Cached_intf=2 Netflow_enabled_intf=1 Live_sessions=0 Session cache max
count:71950
```

NetFlow templates

NetFlow uses templates to capture and categorize the data that it collects. FortiOS supports the following NetFlow templates:

Name	Template ID	Description
STAT_OPTIONS	256	Statistics information about exporter
APP_ID_OPTIONS	257	Application information
IPV4	258	No NAT IPv4 traffic
IPV6	259	No NAT IPv6 traffic
ICMP4	260	No NAT ICMPv4 traffic
ICMP6	261	No NAT ICMPv6 traffic
IPV4_NAT	262	Source/Destination NAT IPv4 traffic
IPV4_AF_NAT	263	AF NAT IPv4 traffic (4->6)
IPV6_NAT	264	Source/Destination NAT IPv6 traffic
IPV6_AF_NAT	265	AF NAT IPv6 traffic (6->4)
ICMP4_NAT	266	Source/Destination NAT ICMPv4 traffic
ICMP4_AF_NAT	267	AF NAT ICMPv4 traffic (4->6)
ICMP6_NAT	268	Source/Destination NAT ICMPv6 traffic
ICMPv6_AF_NAT	269	AF NAT ICMPv6 traffic (6->4)

NetFlow on FortiExtender and tunnel interfaces

NetFlow sampling is supported on FortiExtender and VPN tunnel interfaces.

VPN tunnel interfaces can be IPsec, IP in IP, or GRE tunnels. NetFlow sampling is supported on both NPU and non-NPU offloaded tunnels.

Examples

In the following examples, a FortiExtender and a VPN tunnel interface are configured with NetFlow sampling.

To configure a FortiExtender interface with NetFlow sampling:

1. Configure a FortiExtender interface with NetFlow sampling enabled for both transmitted and received traffic:

```
config system interface
    edit "fext-211"
        set vdom "root"
        set mode dhcp
        set type fext-wan
        set netflow-sampler both
        set role wan
        set snmp-index 8
        set macaddr 2a:4e:68:a3:f4:6a
    next
end
```

2. Check the NetFlow status and configuration:

Device index 26 is the FortiExtender interface fext-211.

```
# diagnose test application sflowd 3
===== Netflow Vdom Configuration =====
Global collector:172.18.60.80:[2055] source ip: 0.0.0.0 active-timeout(seconds):60
inactive-timeout(seconds):600
_____ vdom: root, index=0, is master, collector: disabled (use global config) (mgmt vdom)
|_ coll_ip:172.18.60.80[2055],src_ip:10.6.30.105,seq_num:300,pkts/time to next
template: 18/29
|_ exported: Bytes:3026268, Packets:11192, Sessions:290 Flows:482
|_____ interface:fext-211 sample_direction:both device_index:26 snmp_index:8
```

3. Check the network interface list:

```
# diagnose netlink interface list
...
if=fext-211 family=00 type=1 index=26 mtu=1500 link=0 master=0
ref=27 state=start present fw_flags=60000 flags=up broadcast run multicast
...
```

4. Check the session list for the FortiExtender interface and NetFlow flowset packet:

```
# diagnose sys session list
session info: proto=1 proto_state=00 duration=1732 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty netflow-origin netflow-reply
statistic(bytes/packets/allow_err): org=145572/1733/1 reply=145572/1733/1 tuples=2
tx speed(Bps/kbps): 83/0 rx speed(Bps/kbps): 83/0
origin->sink: org pre->post, reply pre->post dev=5->26/26->5
gwy=10.39.252.244/172.16.200.55
hook=post dir=org act=snat 172.16.200.55:61290->8.8.8.8:8(10.39.252.243:61290)
hook=pre dir=reply act=dnat 8.8.8.8:61290->10.39.252.243:0(172.16.200.55:61290)
misc=0 policy_id=1 auth_info=0 chk_client_info=0 vd=0
serial=00001298 tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpd_b_link_id=00000000 rpd_b_svc_id=0 ngfwid=n/a
npu_state=0x040000
no_ofld_reason: non-npu-intf
total session 1
```

5. The flowset packet can be captured on UDP port 2055 by a packet analyzer, such as Wireshark:

The screenshot displays a network traffic analysis interface. The top section shows a list of packets with columns for No., Time, Source, Destination, Protocol, Length, and Info. The bottom section provides a detailed view of a selected packet, including its version, count, timestamp, source and destination IP addresses, and various protocol details like ICMP, Echo, and Forwarding Status.

No.	Time	Source	Destination	Protocol	Length	Info

To configure a VPN tunnel interface with NetFlow sampling:

1. Configure a VPN interface with NetFlow sampling enabled for both transmitted and received traffic:

```
config system interface
    edit "A-to-B_vpn"
        set vdom "vdom1"
        set type tunnel
        set netflow-sampler both
        set snmp-index 42
        set interface "port3"
    next
end
```

2. Configure the VPN tunnel:

```
config vpn ipsec phase1-interface
    edit "A-to-B_vpn"
        set interface "port3"
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set comments "VPN: A-to-B_vpn [Created by VPN wizard]"
        set wizard-type static-fortigate
        set remote-gw 10.2.2.2
        set psksecret ENC
    next
end

config vpn ipsec phase2-interface
    edit "A-to-B_vpn"
        set phase1name "A-to-B_vpn"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
        set aes256gcm chacha20poly1305
        set comments "VPN: A-to-B_vpn [Created by VPN wizard]"
        set src-addr-type name
        set dst-addr-type name
        set src-name "A-to-B_vpn_local"
```

```

        set dst-name "A-to-B_vpn_remote"
    next
end

```

3. Check the NetFlow status and configuration:

Device index 52 is the VPN interface A-to-B_vpn.

```

# diagnose test application sflowd 3
===== Netflow Vdom Configuration =====
Global collector:172.18.60.80:[2055] source ip: 0.0.0.0 active-timeout(seconds):60

sFlow

sFlow is a method of monitoring the traffic on your network to identify areas on the network that may impact performance and throughput. FortiGate supports sFlow v5. sFlow collector software is available from a number of third-party software vendors. For more information about sFlow, see www.sflow.org.

The packet information that the FortiGate's sFlow agent collects depends on the interface type:

- On an internal interface, when the interface receives packets from devices with private IP addresses, the collected information includes the private IP addresses.
- On an external, or WAN, interface, when the interface receives to route to or from the internet, the collected information includes the IP address of the WAN interface as the source or destination interface, depending on the direction of the traffic. It does not include IP addresses that are NATed on another interface.

sFlow datagrams contain the following information:

- Packet headers, such as MAC, IPv4, and TCP
- Sample process parameters, such as rate and pool
- Input and output ports
- Priority (802.1p and ToS)
- VLAN (802.1Q)
- Source prefixes, destination prefixes, and next hop addresses
- BGP source AS, source peer AS, destination peer AS, communities, and local preference
- User IDs (TACACS, RADIUS) for source and destination
- Interface statistics (RFC 1573, RFC 2233, and RFC 2358)

Configuring sFlow

sFlow can be configured globally, then on traffic VDOMs and individual interfaces.

When configuring sFlow on a VDOM, the collector can be specified, or the collector that is configured globally can be used.

sFlow is supported on some interface types, such as physical, VLAN, and aggregate. It is not supported on virtual interfaces, such as VDOM link, IPsec, GRE, or SSL. When configuring sFlow on an interface, the rate that the agent samples traffic, the direction of that traffic, and the frequency that the agent sends sFlow datagrams to the sFlow collector can be specified. If sFlow is configured on the VDOM that the interface belongs to, the agent sends datagrams to the collector configured for the VDOM. Otherwise, the datagrams are sent to the collector that is configured globally.

Configuring sFlow for an interface disables NP offloading for all traffic on that interface.

To configure sFlow globally:

```
config system sflow
    set collector-ip <ipv4_address>
    set collector-port <port>
    set source-ip <ipv4_address>
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

collector-ip <ipv4_address>	The IPv4 address of the sFlow collector that sFlow agents added to interface (default = 0.0.0.0).
collector-port <port>	The UDP port number used for sending sFlow datagrams (0 - 65535, default = 6343). Only configured this option if required by the sFlow collector or your network configuration.
source-ip <ipv4_address>	The source IPv4 address that the sFlow agent used to send datagrams to the collector (default = 0.0.0.0). If this option is not configured, the FortiGate uses the IP address of the interface that it sends the datagram through.
interface-select-method {auto sdwan specify}	How the outgoing interface to reach the server is selected (default = auto).
interface <interface>	The outgoing interface used to reach the server. This option is only available when interface-select-method is specify.

To configure sFlow for a VDOM:

```
config vdom
    edit <vdom>
        config system vdom-sflow
            set vdom-sflow {enable | disable}
            set collector-ip <ipv4_address>
            set collector-port <port>
            set source-ip <ipv4_address>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        end
    next
end
```

<code>vdom-sflow {enable disable}</code>	Enable/disable the sFlow configuration for the current VDOM (default = disable).
<code>collector-ip <ipv4_address></code>	The IPv4 address of the sFlow collector that sFlow agents added to interface (default = 0.0.0.0). If this option is not configured, the global setting will be used.
<code>collector-port <port></code>	The UDP port number used for sending sFlow datagrams (0 - 65535, default = 6343). Only configured this option if required by the sFlow collector or your network configuration. If this option is not configured, the global setting will be used.
<code>source-ip <ipv4_address></code>	The source IPv4 address that the sFlow agent used to send datagrams to the collector (default = 0.0.0.0). If this option is not configured, the FortiGate uses the IP address of the interface that it sends the datagram through.
<code>interface-select-method {auto sdwan specify}</code>	How the outgoing interface to reach the server is selected (default = auto).
<code>interface <interfae></code>	The outgoing interface used to reach the server. This option is only available when <code>interface-select-method</code> is <code>specify</code> .

To configure sFlow on an interface:

```
config system interface
    edit <interface>
        set sflow-sampler {enable | disable}
        set sample-rate <integer>
        set polling-interval <integer>
        set sample-direction {tx | rx | both}
    next
end
```

<code>sflow-sampler {enable disable}</code>	Enable/disable sFlow on this interface (default = disable).
<code>sample-rate <integer></code>	The average number of packets that the agent lets pass before taking a sample (10 - 99999, default = 2000). Setting a lower rate will sample a higher number of packets, increasing the accuracy or the sampling data, but also increasing the CPU and network bandwidth usage. The default value is recommended.
<code>polling-interval <integer></code>	The amount of time that the agent waits between sending datagrams to the collector, in seconds (1 - 255, default = 20). Setting a higher value lowers the amount of data that the agent sends across the network, but makes the collector's view of the network less current.
<code>sample-direction {tx rx both}</code>	The direction of the traffic that the agent collects (default = both).

Link monitor

The link monitor is a mechanism that allows the FortiGate to probe the status of a detect server in order to determine the health of the link, next hop, or the path to the server. Ping, TCP echo, UDP echo, HTTP, and TWAMP protocols can be used for the probes. Typically, the detect server is set to a stable server several hops away. Multiple servers can also be configured with options to define the protocol and weights for each server.

The link monitor serves several purposes. In the most basic configuration, it can be used to detect failures and remove routes associated with the interface and gateway to prevent traffic from routing out the failed link. More granularity is added in 7.0 that allows only the routes specified in the link monitor to be removed from the routing table. With this benefit, only traffic to specific routing destinations are removed, rather than all routing destinations.

Another enhancement starting in 7.0.1 is an option to toggle between enabling or disabling policy route updates when a link health monitor fails.

The link monitor can also monitor remote servers for HA failover. Using the HA built-in link monitor, it is only able to detect physical link failovers to trigger HA link failover. With the link monitor, remote servers can be used to monitor the health of the path to the server in order to trigger HA failover.

Finally, the link monitor can cascade the failure to other interfaces. When the `update-cascade-interface` option is enabled, the interface can be configured in conjunction with `fail-detect` enabled to trigger a link down event on other interfaces.

The following topics provide more information about the link monitor:

- [Link monitor with route updates on page 602](#)
- [Enable or disable updating policy routes when link health monitor fails on page 604](#)
- [Add weight setting on each link health monitor server on page 606](#)
- [Dual internet connections on page 425](#)
- [SLA link monitoring for dynamic IPsec and SSL VPN tunnels on page 609](#)

Link monitor with route updates

When a link monitor fails, only the routes that are specified in the link monitor are removed from the routing table, instead of all the routes with the same interface and gateway. If no routes are specified, then all of the routes are removed. Only IPv4 routes are supported.

Example

In this example, the FortiGate has several routes to 23.2.2.2/32 and 172.16.202.2/24, and is monitoring the link *agg1* by pinging the server at 10.1.100.22. The link monitor uses the gateway 172.16.203.2.

When the link monitor fails, only the routes to the specified subnet using interface *agg1* and gateway 172.16.203.2 are removed.

To configure the link monitor:

```

config system link-monitor
  edit "22"
    set srcintf "agg1"
    set server "10.1.100.22"
    set gateway-ip 172.16.203.2
    set route "23.2.2.2/32" "172.16.202.0/24"
  next
end

```

To check the results:

1. When the link monitor is alive:

```

# get router info routing-table static
Routing table for VRF=0
S*    0.0.0.0/0 [5/0] via 10.100.1.249, port12
S     10.1.100.0/24 [10/0] via 172.16.203.2, agg1
S     23.2.2.2/32 [10/0] via 172.16.203.2, agg1
S     23.2.3.2/32 [10/0] via 172.16.203.2, agg1
S     172.16.201.0/24 [10/0] via 172.16.200.4, port9
S     172.16.202.0/24 [10/0] via 172.16.203.2, agg1
S     172.16.204.0/24 [10/0] via 172.16.200.4, port9
                                   [10/0] via 172.16.203.2, agg1
                                   [10/0] via 172.16.206.2, vlan100, [100/0]

```

2. When the link monitor is dead:

```

# get router info routing-table static
Routing table for VRF=0
S*    0.0.0.0/0 [5/0] via 10.100.1.249, port12
S     10.1.100.0/24 [10/0] via 172.16.203.2, agg1
S     23.2.3.2/32 [10/0] via 172.16.203.2, agg1
S     172.16.201.0/24 [10/0] via 172.16.200.4, port9
S     172.16.204.0/24 [10/0] via 172.16.200.4, port9
                                   [10/0] via 172.16.203.2, agg1
                                   [10/0] via 172.16.206.2, vlan100, [100/0]

```

Enable or disable updating policy routes when link health monitor fails

An option has been added to toggle between enabling or disabling policy route updates when a link health monitor fails. By disabling policy route updates, a link health monitor failure will not cause corresponding policy-based routes to be removed.

```
config system link-monitor
  edit <name>
    set update-policy-route {enable | disable}
  next
end
```

Example

In the following topology, the FortiGate is monitoring the detect server, 10.1.100.22. The FortiGate has a policy-based route to destination 172.16.205.10 using the same gateway (172.16.202.1) and interface (port22). By configuring `update-policy-route disable`, the policy-based route is not removed when the link health monitor detects a failure.

To disable updating policy routes when the link health monitor fails:

1. Configure the link health monitor:

```
config system link-monitor
  edit "test-1"
    set srcintf "port22"
    set server "10.1.100.22"
    set gateway-ip 172.16.202.1
    set failtime 3
    set update-policy-route disable
  next
end
```

2. Configure the policy route:

```
config router policy
  edit 1
    set input-device "port16"
    set dst "172.16.205.10/255.255.255.255"
    set gateway 172.16.202.1
    set output-device "port22"
    set tos 0x14
    set tos-mask 0xff
```

```

    next
end

```

3. When the health link monitor status is up, verify that the policy route is active.

a. Verify the link health monitor status:

```

# diagnose sys link-monitor status
Link Monitor: test-1, Status: alive, Server num(1), HA state: local(alive), shared
(alive)
Flags=0x1 init, Create time: Fri May 28 15:20:15 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
  Peer: 10.1.100.22(10.1.100.22)
    Source IP(172.16.202.2)
    Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
      protocol: ping, state: alive
        Latency(Min/Max/Avg): 0.374/0.625/0.510 ms
        Jitter(Min/Max/Avg): 0.008/0.182/0.074
        Packet lost: 0.000%
        Number of out-of-sequence packets: 0
        Fail Times(0/3)
        Packet sent: 7209, received: 3400, Sequence(sent/rcvd/exp):
7210/7210/7211

```

b. Verify the policy route list:

```

# diagnose firewall proute list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x0 tos=0x14 tos_mask=0xff protocol=0 sport=0-0 iif=41
dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33

```

4. When the health link monitor status is down, verify that the policy route is active:

a. Verify the link health monitor status:

```

# diagnose sys link-monitor status
Link Monitor: test-1, Status: die, Server num(1), HA state: local(die), shared(die)
Flags=0x9 init log_downgateway, Create time: Fri May 28 15:20:15 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
  Peer: 10.1.100.22(10.1.100.22)
    Source IP(172.16.202.2)
    Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
      protocol: ping, state: die
        Packet lost: 11.000%
        Number of out-of-sequence packets: 0
        Recovery times(0/5) Fail Times(0/3)

```

```
Packet sent: 7293, received: 3471, Sequence(sent/rcvd/exp):
7294/7281/7282
```

b. Verify the policy route list:

```
# diagnose firewall proute list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x0 tos=0x14 tos_mask=0xff protocol=0 sport=0-0 iif=41
dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33
```

If the `update-policy-route` setting is enabled, the link health monitor would be down and the policy-based route would be disabled:

```
# diagnose firewall proute list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x8 disable tos=0x14 tos_mask=0xff protocol=0 sport=0-0
iif=41 dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33
```

Add weight setting on each link health monitor server

Prior to FortiOS 7.0.1, the link health monitor is determined to be dead when all servers are unreachable. Starting in 7.0.1, the link health monitor can configure multiple servers and allow each server to have its own weight setting. When the link health monitor is down, it will trigger static route updates and cascade interface updates if the weight of all dead servers exceeds the monitor's fail weight threshold.

```
config system link-monitor
  edit <name>
    set srcintf <interface>
    set server-config {default | individual}
    set fail-weight <integer>
    config server-list
      edit <id>
        set dst <address>
        set weight <integer>
      next
    end
  next
end
```

server-config	Set the server configuration mode: <ul style="list-style-type: none"> default: all servers share the same attributes. individual: some attributes can be specified for individual servers.
fail-weight <integer>	Threshold weight to trigger link failure alert (0 - 255, default = 0).
server-list	Configure the servers to be monitored by the link monitor.
dst <address>	Enter the IP address of the server to be monitored.
weight <integer>	Weight of the monitor to this destination (0 - 255, default = 0).

Examples

In the following topology, there are two detect servers that connect to the FortiGate through a router: server 1 (10.1.100.22) and server 2 (10.1.100.55).

Alive link health monitor

In this configuration, one server is dead and one server alive. The failed server weight is not over the threshold, so the link health monitor status is alive.

To configure the weight settings on the link health monitor:

1. Configure the link health monitor:

```

config system link-monitor
  edit "test-1"
    set srcintf "port22"
    set server-config individual
    set gateway-ip 172.16.202.1
    set failtime 3
    set fail-weight 40
    config server-list
      edit 1
        set dst "10.1.100.22"
        set weight 60
      next
      edit 2
        set dst "10.1.100.55"
        set weight 30
      next
    end
  next
end

```

2. Trigger server 2 to go down. The link monitor is still alive because the fail weight threshold has not been reached.

3. Verify the link health monitor status:

```
# diagnose sys link-monitor status test-1
Link Monitor: test-1, Status: alive, Server num(2), HA state: local(alive), shared
(alive)
Flags=0x1 init, Create time: Fri Jun  4 17:23:29 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
Fail-weight (40): not activated
  Peer: 10.1.100.22(10.1.100.22)
    Source IP(172.16.202.2)
    Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
    protocol: ping, state: alive
      Latency(Min/Max/Avg): 0.417/0.585/0.530 ms
      Jitter(Min/Max/Avg): 0.007/0.159/0.057
      Packet lost: 0.000%
      Number of out-of-sequence packets: 0
      Fail Times(0/3)
      Packet sent: 239, received: 236, Sequence(sent/rcvd/exp): 240/240/241
  Peer: 10.1.100.55(10.1.100.55)
    Source IP(172.16.202.2)
    Route: 172.16.202.2->10.1.100.55/32, gwy(172.16.202.1)
    Fail weight 30 applied
    protocol: ping, state: dead
      Packet lost: 100.000%
      Number of out-of-sequence packets: 0
      Recovery times(0/5) Fail Times(1/3)
      Packet sent: 239, received: 3, Sequence(sent/rcvd/exp): 240/4/5
```

Dead link health monitor

In this configuration, one server is dead and one server alive. The failed server weight is over the threshold, so the link health monitor status is dead.

To configure the weight settings on the link health monitor:

1. Configure the link health monitor:

```
config system link-monitor
  edit "test-1"
    set srcintf "port22"
    set server-config individual
    set gateway-ip 172.16.202.1
    set failtime 3
    set fail-weight 40
  config server-list
    edit 1
      set dst "10.1.100.22"
      set weight 30
    next
    edit 2
      set dst "10.1.100.55"
```

```

        set weight 50
    next
end
next
end

```

2. Trigger server 2 to go down. The link monitor is dead because the fail weight threshold has been reached.

3. Verify the link health monitor status:

```

# diagnose sys link-monitor status test-1
Link Monitor: test-1, Status: dead, Server num(2), HA state: local(dead), shared(dead)
Flags=0x9 init log_downgateway, Create time: Fri Jun  4 17:23:29 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
Fail-weight (40): activated
  Peer: 10.1.100.22(10.1.100.22)
    Source IP(172.16.202.2)
    Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
    protocol: ping, state: alive
      Latency(Min/Max/Avg): 0.393/0.610/0.520 ms
      Jitter(Min/Max/Avg): 0.009/0.200/0.095
      Packet lost: 0.000%
      Number of out-of-sequence packets: 0
      Fail Times(0/3)
      Packet sent: 680, received: 677, Sequence(sent/rcvd/exp): 681/681/682
  Peer: 10.1.100.55(10.1.100.55)
    Source IP(172.16.202.2)
    Route: 172.16.202.2->10.1.100.55/32, gwy(172.16.202.1)
    Fail weight 50 applied
    protocol: ping, state: dead
      Packet lost: 100.000%
      Number of out-of-sequence packets: 0
      Recovery times(0/5) Fail Times(1/3)
      Packet sent: 680, received: 3, Sequence(sent/rcvd/exp): 681/4/5

```

SLA link monitoring for dynamic IPsec and SSL VPN tunnels

The link health monitor settings can measure SLA information of dynamic VPN interfaces, which assign IP addresses to their clients during tunnel establishment. This includes SSL VPN tunnels, IPsec remote access, and IPsec site-to-site tunnels.

This feature currently only supports IPv4 and the ICMP monitoring protocol. In the IPsec tunnel settings, `net-device` must be disabled.

```

config system link-monitor
  edit <name>
    set server-type {static | dynamic}
  next
end

```

To view the dial-up tunnel statistics:

```
# diagnose sys link-monitor tunnel {name | all} [<tunnel_name>]
```

Example

In this example, endpoint users dial up using FortiClient to create IPsec tunnels with the FortiGate and obtain IP addresses. The link monitor on the FortiGate's dynamic VPN interface detects the path quality to the endpoints.

To configure SLA link health monitoring in dynamic IPsec tunnels:

1. Configure the IPsec phase 1 interface:

```
config vpn ipsec phase1-interface
  edit "for_Branch"
    set type dynamic
    set interface "port15"
    set mode aggressive
    set peertype any
    set net-device disable
    set mode-cfg enable
    set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
    set dpd on-idle
    set dhgrp 5
    set xauthtype auto
    set authusrgrp "vpngroup"
    set assign-ip-from name
    set ipv4-netmask 255.255.255.0
    set dns-mode auto
    set ipv4-split-include "172.16.205.0"
    set ipv4-name "client_range"
    set save-password enable
    set psksecret *****
    set dpd-retryinterval 60
  next
end
```

2. Configure the IPsec phase 2 interface:

```
config vpn ipsec phase2-interface
    edit "for_Branch_p2"
        set phase1name "for_Branch"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
        aes256gcm chacha20poly1305
        set dhgrp 5
    next
end
```

3. Configure the dynamic interface:

```
config system interface
    edit "for_Branch"
        set vdom "root"
        set ip 10.10.10.254 255.255.255.255
        set type tunnel
        set remote-ip 10.10.10.253 255.255.255.0
        set snmp-index 100
        set interface "port15"
    next
end
```

4. Add the IPsec dial-up tunnel to the link health monitor:

```
config system link-monitor
    edit "1"
        set srcintf "for_Branch"
        set server-type dynamic
    next
end
```

5. Once endpoint users have connected using FortiClient, verify the tunnel information:

```
# get vpn ipsec tunnel summary
'for_Branch_0' 10.1.100.23:0 selectors(total,up): 1/1 rx(pkt,err): 21091/0 tx
(pkt,err): 20741/0
'for_Branch_1' 10.1.100.13:0 selectors(total,up): 1/1 rx(pkt,err): 19991/0 tx
(pkt,err): 20381/0
```

6. Verify the link health monitor status:

```
# diagnose sys link-monitor tunnel all
for_Branch_0 (1): state=alive, peer=10.10.10.1, create_time=2022-02-08 10:43:11,
srcintf=for_Branch, latency=0.162, jitter=0.018, pktloss=0.000%
for_Branch_1 (1): state=alive, peer=10.10.10.2, create_time=2022-02-08 10:49:24,
srcintf=for_Branch, latency=0.266, jitter=0.015, pktloss=0.000%
```

7. Manually add 200 ms latency on the path between the FortiGate and FortiClients.**8. Verify the link health monitor status again:**

```
# diagnose sys link-monitor tunnel all
for_Branch_0 (1): state=alive, peer=10.10.10.1, create_time=2022-02-08 10:43:11,
srcintf=for_Branch, latency=200.177, jitter=0.021, pktloss=0.000%
for_Branch_1 (1): state=alive, peer=10.10.10.2, create_time=2022-02-08 10:49:24,
srcintf=for_Branch, latency=200.257, jitter=0.017, pktloss=0.000%
```

IPv6

From an administrative point of view IPv6 works almost the same as IPv4 in FortiOS. The primary difference is the use of IPv6 format for addresses. See [IPv6 overview on page 612](#) for more information.

By default, the IPv6 settings are not displayed in the GUI.

To enable IPv6 in the GUI:

1. Go to *System > Feature Visibility*.
2. Under *Core Features*, enable *IPv6*.
3. Click *Apply*.

Once enabled, you will be able to use IPv6 addresses as well as the IPv4 addressing for the following FortiGate firewall features which are not limited to:

- [Interfaces](#)
- [DHCP Server](#)
- [DHCP Relay](#)
- [DNS](#)
- [Static Routes](#)
- [Firewall Policy](#)
- [NAT](#)
- [Addresses](#)
- [Virtual IPs](#)
- [IP Pools](#)
- [IPsec VPN](#)
- [GRE over IPsec](#)

This section also contains the following topics:

- [IPv6 overview on page 612](#)
- [IPv6 quick start on page 613](#)
- [Neighbor discovery proxy on page 617](#)
- [IPv6 address assignment on page 618](#)
- [NAT66, NAT46, NAT64, and DNS 64 on page 630](#)
- [DHCPv6 relay on page 640](#)
- [IPv6 tunneling on page 641](#)
- [IPv6 configuration examples on page 652](#)

IPv6 overview

Internet Protocol version 6 (IPv6) is the latest version of the Internet Protocol (IP) and was developed to address the limitations of its predecessor, IPv4. The primary issue with IPv4 is its limited number of addresses, which are based on a 32-bit scheme and have a theoretical limit of 2 to the power of 32. In contrast, IPv6 uses a 128-bit address scheme, allowing for a much larger theoretical limit of 2 to the power of 128 addresses.

In simpler terms:

- IPv4 can support 4 294 967 296 addresses.
- IPv6 can support 340 282 366 920 938 463 463 374 607 431 768 211 456 addresses.

In addition to the expanded number of addresses, some of the other benefits of IPv6 include:

- More efficient routing due to reduction in the size of routing tables. This is achieved through hierarchical address allocation, which allows for more efficient routing of data packets.
- Reduced management requirements by supporting stateless auto-reconfiguration of hosts. This means that devices can automatically configure their network settings without the need for manual intervention.
- Improved methods to change Internet Service Providers. With IPv6, it is easier for users to switch between different ISPs without experiencing any service disruption.
- Better mobility support by providing seamless connection. This means that devices can move between different networks without losing their connection.
- Multi-homing. This allows a device to have multiple network connections, providing increased reliability and redundancy.
- Improved security with built-in support for IPsec. IPsec is a security protocol that provides authentication and encryption for data transmitted over a network.
- IPv6 offers scoped addresses with link-local, unique local, and global address spaces. This allows for more flexible addressing and improved network organization.

Address Type	Notation	Description	Example
Link-local Unicast	FE80::/10	Designed for use on a local link and are automatically configured on all interfaces. These addresses are not routable.	FE80::1
Unique Local Unicast	FC00::/7	Similar to IPv4 private addresses and can be used on your own network. They are not routable globally.	FC00::1 FD00::1
Global Unicast	2001::/3	Similar to IPv4 public addresses and can be used on the Internet. They are routable globally.	2001::1 3000::1

See [Internet Protocol Version 6 Address Space](#) for more information.

IPv6 quick start

This section provides an introduction to setting up a few basic IPv6 settings on the FortiGate. See [Basic administration on page 62](#) for more information about basic FortiGate administration.

This chapter provides instructions for basic IPv6 configuration that should work in most cases, regardless of whether the device has an existing IPv4 configuration or is a new FortiGate device.

The topics covered in this section include:

- [Configuring an interface on page 614](#)
- [Configuring the default route on page 614](#)
- [Configuring the DNS on page 615](#)
- [Configuring the address object on page 615](#)

- [Configuring the address group on page 616](#)
- [Configuring the firewall policy on page 616](#)

Before starting, make sure to enable the IPv6 feature.

To enable IPv6 in the GUI:

1. Go to *System > Feature Visibility*.
2. Under *Core Features*, enable *IPv6*.
3. Click *Apply*.

Configuring an interface

To configure an interface in the GUI:

1. Go to *Network > Interfaces*.
2. Select an interface and click *Edit*.
3. In the *Address* section, enter the *IPv6 Address/Prefix*.
4. In the *Administrative Access* section, select the IPv6 access options as needed (such as *PING*, *HTTPS*, and *SSH*).
5. Click *OK*.

To configure an interface in the CLI:

```
config system interface
  edit <interface name>
    config ipv6
      set ip6-address <IPv6 prefix>
      set ip6-allowaccess{ping | https | ssh | snmp | http | telnet | fgfm | fabric}
    end
  next
end
```

Configuring the default route

Setting the default route enables basic routing to allow the FortiGate to return traffic to sources that are not directly connected. The gateway address should be your existing router or L3 switch that the FortiGate is connected to. Set the interface to be the interface the gateway is connected to.

To configure the default route in the GUI:

1. Go to *Network > Static Routes*.
2. Click *Create New > IPv6 Static Route*.
3. Leave the *Destination* prefix as `::/0`. This is known as a default route, since it would match any IPv6 address.
4. Enter the *Gateway Address*.
5. Select an *Interface*.
6. Click *OK*.

To configure the default route in the CLI:

```
config router static6
    edit 0
        set gateway <IPv6 address>
        set device <interface name>
    next
end
```

Configuring the DNS

To configure a DNS domain list in the GUI:

1. Go to *Network > DNS*.
2. Under *IPv6 DNS Settings*, configure the primary and secondary DNS servers as needed.
3. Click *Apply*.

To configure a DNS domain list in the CLI:

```
config system dns
    set ip6-primary <IPv6 address>
    set ip6-secondary <IPv6 address>
end
```

Configuring the address object

Addresses define sources and destinations of network traffic and can be used in many functions such as firewall policies, ZTNA, and so on. When creating an IPv6 address object, several different types of addresses can be specified similar to IPv4 addresses. See [Address Types on page 1303](#) for more information.

To configure an IPv6 address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Select *Create New > Address*.
3. In the *Category* field, select *IPv6 Address*.
4. Enter a *Name* for the address object.
5. In the *Type* field, select one of the types from the dropdown menu.
6. Configure the rest of the settings as required.
7. Click *OK*.

To configure an IPv6 address in the CLI:

```
config firewall address6
    edit <name>
        set type {ipprefix | iprange | fqdn | geography | dynamic | template | mac | route-
tag}
    next
end
```

Configuring the address group

Address groups are designed for ease of use in the administration of the device. See [Address group on page 1319](#) for more information.

To create an address group:

1. Go to *Policy & Objects > Addresses*.
2. Go to *Create New > Address Group*.
3. In the *Category* field, select *IPv6 Group*.
4. Enter a *Group name* for the address object.
5. Select the + in the *Members* field. The *Select Entries* pane opens.
6. Select members of the group. It is possible to select more than one entry. Select the x icon in the field to remove an entry.
7. Enter any additional information in the *Comments* field.
8. Click *OK*.

To configure an address group in the CLI:

```
config firewall addrgrp6
  edit <name>
    set member <name>
  next
end
```

Configuring the firewall policy

A firewall policy must be in place for any traffic that passes through a FortiGate. See [Firewall policy on page 1177](#) for more information.

To create a firewall policy in the GUI:

1. Go to *Policy & Objects > Firewall Policy*.
2. Enter a *Name* and configure the following necessary settings:

Incoming Interface	Incoming (ingress) interface
Outgoing Interface	Outgoing (egress) interface
Source	Source IPv6 address name and address group names
Destination	Destination IPv6 address name and address group names
Schedule	Schedule name
Service	Service and service group names
Action	Policy action

To configure a firewall policy in the CLI:

```
config firewall policy
  edit <policyid>
    set srcintf <name>
    set dstintf <name>
    set action {accept | deny}
    set srcaddr6 <name>
    set dstaddr6 <name>
    set schedule <name>
    set service <name>
  next
end
```

See [IPv6 quick start example on page 652](#) for a sample configuration.

Neighbor discovery proxy

This feature provides support for proxying the IPv6 Neighbor Discovery Protocol (NDP) to allow the following ICMP messages to be forwarded between upstream and downstream interfaces:

- Router Advertisement (RA)
- Neighbor Solicitation (NS)
- Neighbor Advertisement (NA)
- Router Solicitation (RS)
- Redirect

Typically only one interface receives RA traffic, and the interface is automatically considered the upstream interface.

The Neighbor Discovery Protocol (NDP) is a layer 2 protocol that performs several tasks to improve the efficiency and consistency of data transmission across multiple networks and processes. NDP uses ICMPv6 messages to perform the following tasks:

- Stateless auto-configuration: This enables the auto-configuration of IPv6 addresses without the need for a DHCP server. This means that each host on the network can automatically configure its unique IPv6 link-local address and global unicast address.
- Address Resolution: NDP performs a function similar to IPv4's Address Resolution Protocol (ARP), but instead of using ARP, it uses NDP to dynamically resolve IPv6 addresses to their corresponding MAC addresses.
- Neighbor Unreachability Detection (NUD): This function detects when a host is no longer reachable, allowing for more efficient routing and data transmission.
- Duplicate Address Detection (DAD): This function verifies that there is no duplication of unicast IPv6 addresses in the network, ensuring that each host has a unique address.

Configure ND proxy in the CLI using the following syntax:

```
config system nd-proxy
  set status {enable|disable}
  set member <interface> <interface> [<interface>...]
end
```

Option	Description
status	Enable/disable the use of neighbor discovery proxy.
member	List of interfaces using the neighbor discovery proxy.

In this example, the client is connected to a FortiGate device that is configured as an ND (Neighbor Discovery) proxy. Port1 is the upstream interface that receives Router Advertisement (RA) traffic, and port5 is the downstream interface that connects to the client. This setup allows the FortiGate device to facilitate communication between the client and the IPv6 router.

To configure ND Proxy on FortiGate:

1. Enable address auto-configuration on the upstream interface:

```

config system interface
    edit "port1"
        config ipv6
            set autoconf enable
        end
    next
end

```

2. Enable ND proxy on the interfaces:

```

config system nd-proxy
    set status enable
    set member "port1" "port5"
end

```

See [RFC 4389](#) for more information on Neighbor Discovery Proxies (ND Proxy).

IPv6 address assignment

On the FortiGate, an interface can use the following methods to obtain an IPv6 address:

- [IPv6 stateless address auto-configuration \(SLAAC\) on page 619](#)
- [DHCPv6 stateful server on page 620](#)
- [SLAAC with DHCPv6 stateless server on page 622](#)
- [IPv6 prefix delegation on page 624](#)

You can configure IPv6 using the CLI. To configure IPv6 using the GUI, ensure IPv6 is enabled by going to *System > Feature Visibility* and enabling *IPv6*.

IPv6 stateless address auto-configuration (SLAAC)

FortiGate can easily obtain an IPv6 address on any given interface using SLAAC (stateless address auto-configuration). SLAAC is designed only for IP assignments and does not provide DNS server addresses to hosts. See [RFC 4862](#) for more information.

Use one of the following options to obtain a DNS server address:

- [DHCPv6 stateful server on page 620](#)
- [SLAAC with DHCPv6 stateless server on page 622](#)

In this example, Server-Fgt is connected to Client-Fgt. Server-Fgt has SLAAC enabled, which allows Client-Fgt to automatically obtain an IPv6 address using the auto-configuration IPv6 address option.

To enable IPv6 auto-configuration in the GUI:

1. Configure SLAAC on Server-Fgt:

- Go to *Network > Interfaces* and edit port5.
- Configure the following settings:

IPv6 addressing mode	Manual
IPv6 Address/Prefix	2001:db8:d0c:1::1/64
Stateless Address Auto-configuration (SLAAC)	Enable
IPv6 prefix list	Enable
IPv6 prefix	2001:db8:d0c:1::/64

- Click OK.

2. Configure Client-Fgt to automatically obtain an IPv6 address:

- Go to *Network > Interfaces* and edit port5.
- Enable *Auto configure IPv6 address*. Client-Fgt uses the prefix that it obtains from the Server-Fgt interface, and automatically generates an IPv6 address.

3. Verify that Client-Fgt automatically generated an IPv6 address:

- Go to *Network > Interfaces* and edit port5. The *IPv6 Address/Prefix* field is populated with an IPv6 address.

To enable IPv6 auto-configuration in the CLI:

1. Configure SLAAC on Server-Fgt:

```
config system interface
  edit "port5"
    config ipv6
      set ip6-address 2001:db8:d0c:1::1/64
      set ip6-send-adv enable
      config ip6-prefix-list
        edit 2001:db8:d0c:1::/64
        next
      end
    end
  next
end
```

2. Configure Client-Fgt to automatically obtain an IPv6 address:

```
config system interface
  edit "port5"
    config ipv6
      set autoconf enable
    end
  next
end
```

3. Verify that Client-Fgt automatically generated an IPv6 address:

```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2001:db8:d0c:1:20c:29ff:fe4d:f83d
preferred=604419 valid=2591619 cstamp=976270 tstamp=979470
```

DHCPv6 stateful server

Similar to a DHCPv4 server, a DHCPv6 server is stateful. It can track client/server states, assign IP addresses to clients, and maintain full control over the process. In addition to assigning IP addresses, a DHCP server can also provide DNS server addresses. However, this IP address assignment method does not support failover protection. If the DHCPv6 server fails, hosts are unable to obtain an IPv6 address, and the network ceases to function. Furthermore, DHCPv6 does not provide gateway information. See [RFC 3315](#) for more information.

In this example, Server-Fgt is connected to Client-Fgt. Server-Fgt has a stateful DHCPv6 server configured that allows Client-Fgt to automatically obtain an IPv6 address and DNS server address using the DHCP option.

To configure a DHCPv6 stateful server in the GUI:

1. Configure the Server-Fgt with DHCPv6 stateful server:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Configure the following settings:

DHCPv6 Server	Enable
IPv6 subnet	2001:db8:d0c:1::/64
DNS service	Same as System DNS
Stateful server.	Enable
IP mode	IP range
Address range	2001:db8:d0c:1::a to 2001:db8:d0c:1::f

- c. Click OK.
2. Configure Client-Fgt to obtain an IPv6 address using DHCP:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Set *IPv6 addressing mode* to *DHCP*.
 - c. Click OK.
3. Verify that Client-Fgt obtained an IPv6 address and DNS server address from the DHCPv6 server:
 - a. Go to *Network > Interfaces* and edit port5. The *Obtained IP/Netmask* and *Acquired DNS* fields are populated with an IPv6 address.

To configure a DHCPv6 stateful server in the CLI:

1. Configure Server-Fgt with DHCPv6 stateful server:

```
config system dhcp6 server
  edit 1
    set dns-service default
    set subnet 2001:db8:d0c:1::/64
    set interface "port5"
    config ip-range
      edit 1
        set start-ip 2001:db8:d0c:1::a
        set end-ip 2001:db8:d0c:1::f
      next
    end
  next
end
```

2. Configure Client-Fgt to obtain an IPv6 address using DHCP:

```
config system interface
  edit "port5"
    config ipv6
      set ip6-mode dhcp
    end
  next
end
```

3. Verify that Client-Fgt obtained an IPv6 address and DNS server address from the DHCPv6 server:

```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag=P scope=0 prefix=128 addr=2001:db8:d0c:1::a
preferred=4294967295 valid=4294967295 cstamp=1298969 tstamp=1298969ip6-address
# dia test application dnsproxy 3
worker idx: 0
```

```

VDM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::ff:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0
probe=0 failure=1 last_failed=19812

```

SLAAC with DHCPv6 stateless server

Using Stateless Address Auto Configuration (SLAAC) with a stateless DHCPv6 server provides a solution for obtaining other host configurations, such as DNS server addresses, while retaining the auto-configuration aspect of SLAAC. This approach also provides failover protection in the event that the DHCPv6 server fails. In addition to obtaining host configurations through the stateless DHCPv6 server, interfaces can also obtain gateway information through Router Advertisements (RAs). This allows for a robust and flexible IPv6 network configuration.

In this example, Server-Fgt is connected to Client-Fgt. Server-Fgt has both SLAAC and stateless DHCPv6 server enabled. This allows Client-Fgt to automatically obtain an IPv6 address using the *Auto configure IPv6 address* option and to acquire a DNS server address using the `dhcp6-information-request` option.

To enable IPv6 auto-configuration with DHCPv6 stateless server in the GUI:

1. Configure SLAAC on Server-Fgt:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Configure the following settings:

IPv6 addressing mode	Manual
IPv6 Address/Prefix	2001:db8:d0c:1::1/64
Stateless Address Auto-configuration (SLAAC)	Enable
IPv6 prefix list	Enable
IPv6 prefix	2001:db8:d0c:1::/64

- c. Click OK.
- d. Input the following commands from the CLI:

```

config system interface
  edit "port5"
    config ipv6
      set ip6-other-flag enable
    end
  next
end

```

2. Configure DHCPv6 stateless server on the Server-Fgt:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Configure the following settings:

DHCPv6 Server	Enable
DNS service	Same as System DNS
Stateful server	Disable

c. Click OK.

3. Configure Client-Fgt to automatically obtain an IPv6 address and DNS server address from the DHCPv6 server:

- a. Go to *Network > Interfaces* and edit port5.
- b. Enable *Auto configure IPv6 address*. Client-Fgt uses the prefix obtained from the Server-Fgt interface to automatically generate an IPv6 address.
- c. Input the following commands from the CLI:

```
config system interface
  edit "port5"
    config ipv6
      set dhcp6-information-request enable
    end
  next
end
```

d. Click OK.

4. Verify that Client-Fgt automatically generated an IPv6 address and obtained the DNS server address from the DHCPv6 server:

- a. Go to *Network > Interfaces* and edit port5. The IPv6 Address/Prefix field is populated with an IPv6 address
- b. Use the below CLI command to verify the DNS server address:

```
#dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::1:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0
probe=0 failure=1 last_failed=46738
...
```

To enable IPv6 autoconfiguration with DHCPv6 stateless server in the CLI:

1. Configure SLAAC on Server-Fgt:

```
config system interface
  edit "port5"
    config ipv6
      set ip6-address 2001:db8:d0c:1::1/64
      set ip6-send-adv enable
      set ip6-other-flag enable
      config ip6-prefix-list
        edit 2001:db8:d0c:1::/64
      next
    end
  next
end
```

2. Configure DHCPv6 stateless server on the Server-Fgt:

```

config system dhcp6 server
  edit 1
    set dns-service default
    set interface "port5"
  next
end

```

3. Configure the Client-Fgt to obtain an IPv6 address automatically:

```

config system interface
  edit "port5"
    config ipv6
      set autoconf enable
      set dhcp6-information-request enable
    end
  next
end

```

4. Verify that Client-Fgt automatically generated an IPv6 address and obtained the DNS server address from the DHCPv6 server:

```

# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2001:db8:d0c:1:20c:29ff:fe4d:f83d
preferred=604681 valid=2591881 cstamp=1675487 tstamp=1772919
# dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::1:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0
probe=0 failure=1 last_failed=46738
...

```

IPv6 prefix delegation

IPv6 prefix delegation allows the dynamic assignment of an address prefix and DNS server address to an upstream interface. An upstream interface is typically the interface that is connected to an Internet Service Provider (ISP). This process also automates the assignment of prefixes to downstream interfaces. A downstream interface is any interface that is not an upstream interface and uses delegated addressing mode. Downstream interfaces can be configured to request specific IPv6 subnets from the upstream interface. Once a downstream interface receives the IPv6 address, other devices connected to the downstream interface can obtain an IPv6 address by using DHCPv6 or by configuring their own IP address using auto-configuration.

In this example, Server-Fgt is connected to a DHCPv6 server provided by the ISP through an upstream interface (port1). Server-Fgt is configured with a delegate interface (port5) to receive the IPv6 prefix and DNS server address from the upstream interface.

A downstream interface (port5) connects Client-Fgt to Server-Fgt. The Client-Fgt interface (port5) is configured to receive the IPv6 address and DNS server address from the Server-FortiGate using DHCP addressing mode or auto-configuration.

Using the GUI or CLI to configure a downstream FortiGate to obtain the IPv6 and DNS server address from delegated interface using DHCP mode requires the following steps:

1. Configure the following items on Server_FGT:
 - Upstream interface
 - Downstream interface
 - DHCPv6 server on the downstream interface.
2. Configure Client_FGT to receive IPv6 prefix and DNS from the delegated interface.

Instead of configuring a DHCPv6 server on the downstream interface of Server_FGT, you can configure SLAAC. See [IPv6 prefix delegation with SLAAC on page 628](#).

GUI configuration

To configure Server_FGT:

1. Configure the upstream interface on Server-Fgt:
 - a. Go to *Network > Interfaces* and edit the port1.
 - b. Enable *DHCPv6 prefix delegation*.
 - c. Select the + in the IAPD prefix hint to open the ID and prefix field.
 - d. Enter 1 for *ID* and *::/48* for *prefix* field. You can add two or more entries. Select the x icon in the field to remove an entry.

The screenshot shows the 'Edit Interface' window. Under the 'DHCPv6 prefix delegation' section, the toggle switch is turned on. Below it, the 'IAPD 1 prefix hint' section contains a table with two columns: 'ID' and 'Prefix'. The first row has '1' in the ID column and '::/48' in the Prefix column. There is a plus icon (+) to add more entries and an 'x' icon to remove an entry.

ID	Prefix
1	::/48

- e. Click OK.
2. Verify upstream interface obtained the prefix delegation, see [Verify upstream interface obtained prefix delegation and DNS server address](#).
3. Configure the downstream interface on Server-Fgt:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Set *IPv6 addressing mode* to *Delegated*.
 - c. Enter 1 for *Identity association identifier* field.
 - d. Set *IPv6 upstream* interface to *port1*.
 - e. Click OK.
4. Verify downstream interface obtained an IPv6 Address/Prefix:
 - a. Go to *Network > Interfaces* and edit port5. The IPv6 Address/Prefix field is populated with an IPv6 Address/Prefix.
5. Configure DHCPv6 Server on the downstream interface:
 - a. Go to *Network > Interfaces* and edit the port5
 - b. Enable *DHCPv6 Server*.
 - c. Set *DNS service* to *Delegated*.
 - d. From the *Upstream interface* dropdown list, select *port1*.
 - e. Input the following commands from the CLI:

```
config system dhcp6 server
    edit 1
        set delegated-prefix-iaid 1
    next
end
```

- f. Enable *Stateful server*.
- g. Set *IP mode* to *Delegated*.
- h. Click *OK*.

To configure Client_FGT:

1. Configure the Client-Fgt interface using DHCP mode:
 - a. Go to *Network > Interfaces* and edit the port5.
 - b. Set *IPv6 addressing mode* to *DHCP*. This allows Client_Fgt to obtain the IPv6 prefix and DNS from the delegated interface.
 - c. Click *OK*.
2. Verify that Client-Fgt obtained an IPv6 address and the DNS server address from the delegated interface:
 - a. Go to *Network > Interfaces* and edit port5. The *Obtained IP/Netmask* and *Acquired DNS* fields are populated with an IPv6 address.

CLI configuration

Using the CLI to configure a downstream FortiGate to obtain the IPv6 and DNS server address from delegated interface using DHCP mode requires the following steps:

To configure Server_FGT:

1. Configure the upstream interface on Server-Fgt:

```
config system interface
    edit "port1"
        config ipv6
            set dhcp6-prefix-delegation enable
            config dhcp6-iapd-list
                edit 1
                    set prefix-hint ::/48
                next
            end
        end
    next
end
```

2. Verify upstream interface obtained prefix delegation and DNS server address:

```
config system interface
    edit port1
        config ipv6
Server-Fgt # get
ip6-mode          : static
```

```

...
dhcp6-prefix-delegation: enable
delegated-prefix iaid 1      : 2001:db8:d0c::/48
preferred-life-time          : 4294967295
valid-life-time              : 4294967295
delegated-DNS1              : 2001:db8::35
delegated-DNS2               : ::
...
dhcp6-iapd-list:
  == [ 1 ]
    iaid:      1      prefix-hint: ::/48      prefix-hint-plt: 604800
    prefix-hint-vlt: 2592001

```

3. Configure the downstream interface on Server-Fgt:

```

config system interface
  edit "port5"
    config ipv6
      set ip6-mode delegated
      set ip6-delegated-prefix-iaid 1
      set ip6-upstream-interface "port1"
    end
  next
end

```

4. Verify downstream interface obtained an IPv6 Address/Prefix:

```

config system interface
  edit "port5"
    config ipv6
Server-Fgt # get
ip6-mode          : delegated
nd-mode           : basic
ip6-address       : 2001:db8:d0c::/48
...
ip6-delegated-prefix-iaid: 1
ip6-upstream-interface: port1
ip6-subnet        : ::/0

```

5. Configure DHCPv6 server on the downstream interface:

```

config system dhcp6 server
  edit 1
    set dns-service delegated
    set interface "port5"
    set upstream-interface "port1"
    set delegated-prefix-iaid 1
    set ip-mode delegated
  next
end

```

To configure Client_FGT:

1. Configure Client-Fgt interface to use DHCP mode:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-mode dhcp
        end
    next
end
```

2. Verify Client-Fgt obtained an IPv6 address and the DNS server address from the delegated interface:

```
# diagnose ipv6 address list | grep port5
dev=7 devname=port5 flag=P scope=0 prefix=128 addr=2001:db8:d0c::1
preferred=4294967295 valid=4294967295 cstamp=43208325 tstamp=43208325
# dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8::35:53 vrf=0 tz=0 encrypt=none req=3 to=2 res=0 rt=1046 ready=1 timer=0
probe=0 failure=2 last_failed=65131
```

IPv6 prefix delegation with SLAAC

A downstream FortiGate can be configured to obtain the IPv6 address and DNS server address from a delegated interface using SLAAC instead of DHCPv6. Following is a summary of the configuration steps:

1. Configure the following items on Server_FGT:
 - Upstream interface
 - Downstream interface
 - SLAAC on the downstream interface
2. Configure Client_FGT to receive IPv6 prefix and DNS from the delegated interface.

To configure Server_FGT:

1. Configure the upstream interface on Server-Fgt:
 - a. Go to *Network > Interfaces* and edit the port1.
 - b. Enable *DHCPv6 prefix delegation*.
 - c. Select the + in the IAPD prefix hint to open the ID and prefix field.
 - d. Enter 1 for *ID* and *::/48* for *prefix* field. You can add two or more entries. Select the x icon in the field to remove an entry.

ID	Prefix
1	::/48

- e. Click OK.

2. Verify upstream interface obtained the prefix delegation, see [Verify upstream interface obtained prefix delegation and DNS server address](#).
3. Configure the downstream interface on Server-Fgt:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Set *IPv6 addressing mode* to *Delegated*.
 - c. Enter 1 for *Identity association identifier* field.
 - d. Set *IPv6 upstream interface* to *port1*.
 - e. Click OK.
4. Verify downstream interface obtained an IPv6 Address/Prefix:
 - a. Go to *Network > Interfaces* and edit port5. The IPv6 Address/Prefix field is populated with an IPv6 Address/Prefix.
5. Configure SLAAC on downstream interface:

```
config system interface
  edit "port5"
    config ipv6
      set ip6-mode delegated
      set ip6-send-adv enable
      set ip6-delegated-prefix-iaid 1
      set ip6-upstream-interface "port1"
      config ip6-delegated-prefix-list
        edit 1
          set upstream-interface "port1"
          set delegated-prefix-iaid 1
          set subnet 0:0:0:1::/64
          set rdns-service delegated
        next
      end
    end
  next
end
```

To configure Client_FGT:

1. Configure Client-Fgt interface using auto-configure:

```
config system interface
  edit "port5"
    config ipv6
      set autoconf enable
    end
  next
end
```

2. Verify Client-Fgt automatically generated an IPv6 address and obtained the DNS server address from the delegated interface:

```
# diagnose ipv6 address list | grep port5
```

```
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2000:db8:d0c:1:20c:29ff:fe4d:f847
preferred=4294967295 valid=4294967295 cstamp=17203697 tstamp=17225377
```

FortiGate can send DNS server addresses using Router Advertisement (RA), which allows any device that is capable of receiving DNS server addresses by using RA to obtain DNS server addresses.

Additionally, FortiGate can receive DNS server addresses through the use of SLAAC with a DHCPv6 stateless server, even though it is currently unable to receive DNS server addresses using RA due to [RFC 4862](#) implementation. See [SLAAC with DHCPv6 stateless server on page 622](#) for more information.

NAT66, NAT46, NAT64, and DNS 64

Multiple NAT46 and NAT64 related objects are consolidated into regular objects. A per-VDOM virtual interface, `naf.<vdom>`, is automatically added to process NAT46 and NAT64 traffic. The features include:

- `vip46` and `vip64` settings are consolidated in `vip` and `vip6` configurations.
- `policy46` and `policy64` settings are consolidated in `firewall policy` settings.
- `nat46` and `nat64` are included in `firewall policy` settings.
- `ippool` and `ippool6` support NAT46 and NAT64 (when enabled, the IP pool should match a subnet).
- Central SNAT supports NAT46 and NAT64.
- `add-nat46-route` in `ippool6` and `add-nat64-route` in `ippool` are enabled by default. The FortiGate generates a static route that matches the IP range in `ippool6` or `ippool` for the `naf` tunnel interface.

Automatic processing of the `naf` tunnel interface is not supported in security policies.

To configure NAT46 or NAT64 translation, use the standard `vip` or `vip6` setting, apply it in a firewall policy, enable NAT46 or NAT64, and enter the IP pool to complete the configuration.

The external IP address cannot be the same as the external interface IP address.

This section includes:

- [NAT66 policy on page 630](#)
- [NAT46 policy on page 632](#)
- [NAT64 policy and DNS64 \(DNS proxy\) on page 635](#)

NAT66 policy

NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. NAT66 is not as common or as important as IPv4 NAT, as many IPv6 addresses do not need NAT66 as much as IPv4 NAT. However, NAT66 can be useful for a number of reasons. For example, you may have changed the IP addresses of

some devices on your network but want traffic to still appear to be coming from their old addresses. You can use NAT66 to translate the source addresses of packets from the devices to their old source addresses.

In FortiOS, NAT66 options can be added to an IPv6 security policy. Configuring NAT66 is very similar to configuring NAT in an IPv4 security policy.

To configure NAT66:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New*.
3. Configure the required policy parameters.
4. Enable *NAT* and select *Use Outgoing Interface Address*. For packets that match this policy, its source IP address is translated to the IP address of the outgoing interface.
5. Click *OK*.

Nat66 can also translate one IPv6 source address to another address that is not the same as the address of the existing interface. You can do this using IP pools.

To configure the IPv6 pool:

1. Go to *Policy & Objects > IP Pools*.
2. Click *Create New*.
3. Enter the following:

IP Pool Type	IPv6 Pool
Name	test-ippool6-1
External IP Range	2000:172:16:101::1-2000:172:16:101::1

4. Click *OK*.

To use the IPv6 pool in the firewall policy:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New* or edit an existing policy.
3. Configure the required policy parameters.
4. Enable *NAT* and select *Use Dynamic IP Pool*.
5. Click *OK*.

NAT66 destination address translation

NAT66 can also be used to translate destination addresses. This is done in an IPv6 policy by using IPv6 virtual IPs. For example, the destination address 2001:db8::dd can be mapped to 2001:db8::ee.

To configure the IPv6 VIP:

1. Go to *Policy & Objects > Virtual IPs*.
2. Click *Create New*.

- Enter the following:

VIP type	IPv6
Name	example-vip6
External IP address/range	2001:db8::dd
Map to IPv6 address/range	2001:db8::ee

- Click **OK**.

To use the IPv6 VIP in the firewall policy:

- Go to *Policy & Objects > Firewall Policy*.
- Click *Create New* or edit an existing policy.
- Configure the required policy parameters.
- In the *Destination* field, select *example-vip6* from the dropdown menu.
- Click **OK**.

NAT46 policy

NAT46 refers to the mechanism that allows IPv4 addressed hosts to communicate with IPv6 hosts. Without such a mechanism, IPv4 environments cannot connect to IPv6 networks.

Sample topology

In this example, an IPv4 client tries to connect to an IPv6 server. A VIP is configured on FortiGate to map the server IPv6 IP address `2000:172:16:200:55` to an IPv4 address `10.1.100.55`. On the other side, an IPv6 IP pool is configured and the source address of packets from client are changed to the defined IPv6 address. In this setup, the client PC can access the server by using IP address `10.1.100.55`.

Sample configuration

To configure NAT46 in the GUI:

- Enable IPv6:
 - Go to *System > Feature Visibility*.
 - In the *Core Features* section, enable *IPv6*.
 - Click *Apply*.
- Configure the VIP:

- a. Go to *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP*.
- b. Enter the following:

VIP type	IPv4
Name	vip46_server
Interface	port2
Type	Static NAT
External IP address/range	10.1.100.55
Map to IPv6 address/range	2000:172:16:200::55

- c. Click *OK*.

3. Configure the IPv6 IP pool:

- a. Go to *Policy & Objects > IP Pools* and click *Create New*.
- b. Enter the following:

IP Pool Type	IPv6 Pool
Name	client_external
External IP address/range	2000:172:16:201::-2000:172:16:201::7
NAT46	Enable

- c. Click *OK*.

4. Configure the firewall policy:

- a. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
- b. Enter the following:

Name	policy46-1
Incoming Interface	port10
Outgoing Interface	port9
Source	all
Destination	vip46_server
Schedule	always
Service	ALL
Action	ACCEPT
NAT	NAT46
IP Pool Configuration	client_external

- c. Configure the other settings as needed.
- d. Click *OK*.

To configure NAT46 in the CLI:**1. Enable IPv6:**

```
config system global
    set gui-ipv6 enable
end
```

2. Configure the VIP:

```
config firewall vip
    edit "vip46_server"
        set extip 10.1.100.55
        set nat44 disable
        set nat46 enable
        set extintf "port2"
        set ipv6-mappedip 2000:172:16:200::55
    next
end
```

3. Configure the IPv6 IP pool:

```
config firewall ippool6
    edit "client_external"
        set startip 2000:172:16:201::
        set endip 2000:172:16:201::7
        set nat46 enable
    next
end
```

4. Configure the firewall policy:

```
config firewall policy
    edit 2
        set name "policy46-1"
        set srcintf "port10"
        set dstintf "port9"
        set action accept
        set nat46 enable
        set srcaddr "all"
        set dstaddr "vip46_server"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set ippool enable
        set poolname6 "client_external"
    next
end
```

Sample troubleshooting

To trace the flow and troubleshoot:

```
# diagnose debug flow filter saddr 10.1.100.11
# diagnose debug flow show function-name enable
show function name
# diagnose debug flow show iprope enable
show trace messages about iprope
# diagnose debug flow trace start 5

NAT64 policy and DNS64 (DNS proxy)

NAT64 policy translates IPv6 addresses to IPv4 addresses so that a client on an IPv6 network can communicate transparently with a server on an IPv4 network.

NAT64 policy is usually implemented in combination with the DNS proxy called DNS64. DNS64 synthesizes AAAA records from A records and is used to synthesize IPv6 addresses for hosts that only have IPv4 addresses. DNS proxy and DNS64 are interchangeable terms.

Sample topology

In this example, a host on the internal IPv6 network communicates with `ControlPC.qa.fortinet.com` that only has IPv4 address on the Internet. Central NAT is disabled.

1. The host on the internal network does a DNS lookup for `ControlPC.qa.fortinet.com` by sending a DNS query for an AAAA record for `ControlPC.qa.fortinet.com`.
2. The DNS query is intercepted by the FortiGate DNS proxy. The DNS proxy performs an A-record query for `ControlPC.qa.fortinet.com` and gets back an RRSet containing a single A record with the IPv4 address `172.16.200.55`.
3. The DNS proxy then synthesizes an AAAA record. The IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits and the received IPv4 address in the lower 32 bits. By default, the resulting IPv6 address is `64:ff9b::172.16.200.55`.
4. The host on the internal network receives the synthetic AAAA record and sends a packet to the destination address `64:ff9b::172.16.200.55`.
5. The packet is routed to the FortiGate internal interface (port10) where it is accepted by the NAT64 security policy.
6. The FortiGate translates the destination address of the packets from IPv6 address `64:ff9b::172.16.200.55` to IPv4 address `172.16.200.55` and translates the source address of the packets to `172.16.200.200` (or another address in the IP pool range) and forwards the packets out the port9 interface to the Internet.

Sample configuration

To configure a NAT64 policy with DNS64 in the GUI:

1. Enable IPv6 and DNS database:
 - a. Go to *System > Feature Visibility*.
 - b. In the *Core Features* section, enable *IPv6*.
 - c. In the *Additional Features* section, enable *DNS Database*.
 - d. Click *Apply*.
2. Enable DNS proxy on the IPv6 interface:
 - a. Go to *Network > DNS Servers*.
 - b. In the *DNS Service on Interface* table, click *Create New*.
 - c. For *Interface*, select *port10*.
 - d. For *Mode*, select *Forward to System DNS*.
 - e. Click *OK*.
3. Configure the IPv6 DHCP server:

- a. Go to *Network > Interfaces* and edit port10.
- b. Enable *DHCPv6 Server* and enter the following:

IPv6 subnet	2001:db8:1::/64
DNS service	Specify
DNS server 1	2001:db8:1::10

- c. Click *OK*.

4. Configure the IPv6 VIP for the destination IPv6 addresses:

These are all of the IPv6 addresses that the FortiGate DNS proxy synthesizes when an IPv6 device performs a DNS query that resolves to an IPv4 Address. In this example, the synthesized IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits, so the VIP is for all the IPv6 addresses that begin with 64:ff9b.

- a. Go to *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP*.
- b. Enter the following:

VIP type	IPv6
Name	vip6
Eternal IP address/range	64:ff9b::-64:ff9b::ffff:ffff
Map to IPv4 address/range	Use Embedded

- c. Click *OK*.

5. Configure the IPv6 firewall address for the internal network:

- a. Click *Create New > Address*.
- b. Enter the following:

Category	IPv6 Address
Name	internal-net6
Type	IPv6 Subnet
IP/Netmask	2001:db8:1::/48

- c. Click *OK*.

6. Configure the IP pool containing the IPv4 address that is used as the source address of the packets exiting port9:

- a. Go to *Policy & Objects > IP Pools* and click *Create New*.
- b. Enter the following:

IP Pool Type	IPv4 Pool
Name	exit-pool4
Type	Overload
External IP address/range	172.16.200.200-172.16.200.207
NAT64	Enable

External IP address/range must start and end on the boundaries of a valid subnet. For example, 172.16.200.0-172.16.200.7 and 172.16.200.16-172.16.200.31 are a valid subnets (/29 and /28 respectively).

c. Click OK.

7. Configure the NAT64 policy:

a. Go to *Policy & Objects > Firewall Policy* and click *Create New*.

b. Enter the following:

Name	policy64-1
Incoming Interface	port10
Outgoing Interface	port9
Source	internal-net6
Destination	vip6
Schedule	always
Service	ALL
Action	ACCEPT
NAT	NAT64
IP Pool Configuration	exit-pool4

c. Click OK.

To configure a NAT64 policy with DNS64 in the CLI:

1. Enable IPv6 and DNS database:

```
config system global
    set gui-ipv6 enable
end

config system settings
    set gui-dns-database enable
end
```

2. Enable DNS proxy on the IPv6 interface:

```
config system dns-server
    edit "port10"
        set mode forward-only
    next
end
```

3. Configure the IPv6 DHCP server:

```
config system dhcp6 server
    edit 1
        set subnet 2001:db8:1::/64
        set interface "port10"
        set dns-server1 2001:db8:1::10
```

```
    next
end
```

4. Configure the IPv6 VIP for the destination IPv6 addresses:

```
config firewall vip6
    edit "vip6"
        set extip 64:ff9b::-64:ff9b::ffff:ffff
        set embedded-ipv4-address enable
    next
end
```

5. Configure the IPv6 firewall address for the internal network:

```
config firewall address6
    edit "internal-net6"
        set ip6 2001:db8:1::/48
    next
end
```

6. Configure the IP pool containing the IPv4 address that is used as the source address of the packets exiting port9:

```
config firewall ippool
    edit "exit-pool4"
        set startip 172.16.200.200
        set endip 172.16.200.207
        set nat64 enable
    next
end
```

External IP address/range must start and end on the boundaries of a valid subnet. For example, 172.16.200.0-172.16.200.7 and 172.16.200.16-172.16.200.31 are a valid subnets (/29 and /28 respectively).

7. Configure the NAT64 policy:

```
config firewall policy
    edit 1
        set name "policy64-1"
        set srcintf "port10"
        set dstintf "port9"
        set action accept
        set nat64 enable
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 internal-net6
        set dstaddr6 vip6
        set schedule "always"
        set service "ALL"
        set ippool enable
        set poolname "exit-pool4"
    next
end
```

To enable DNS64 and related settings using the CLI:

Enabling DNS64 means that all IPv6 traffic received by the current VDOM can be subject to NAT64 if the source and destination address matches an NAT64 security policy.

By default, the setting `always-synthesize-aaaa-record` is enabled. If you disable this setting, the DNS proxy (DNS64) will attempt to find an AAAA records for queries to domain names and therefore resolve the host names to IPv6 addresses. If the DNS proxy cannot find an AAAA record, it synthesizes one by adding the NAT64 prefix to the A record.

```
config system dns64
    set status {enable | disable}
    set dns64-prefix <ipv6-prefix>
    set always-synthesize-aaaa-record {enable | disable}
end
```

By default, the `dns64-prefix` is `64:ff9b::/96`.

DHCPv6 relay

Similar to DHCPv4, DHCPv6 facilitates communication between networks by relaying queries and responses between a client and a DHCP server on separate networks. The FortiGate device serves as a DHCPv6 relay agent and forwards DHCPv6 messages between clients and servers. The relay agent receives DHCPv6 messages from clients and forwards them to the appropriate DHCPv6 server. In response, the server sends a message containing configuration information for the client, which the relay agent forwards to the client. This enables seamless information exchange between the two networks.

Configure DHCPv6 relay in the CLI using the following syntax:

```
config system interface
    edit <interface>
        config ipv6
            set dhcp6-relay-service {enable|disable}
            set dhcp6-relay-type regular
            set dhcp6-relay-ip <ip6-address>
        end
    end
next
end
```

In this example, a client connects to a FortiGate device that is configured to function as a DHCPv6 relay. Port1 on the FortiGate device connects to a DHCPv6 server, and port5 is configured as a DHCPv6 relay. The DHCPv6 server has an IP address of `2000:db8:d0c::a`. This configuration enables the FortiGate device to facilitate communication between the client and the DHCPv6 server on separate networks.

To configure DHCPv6 relay on the FortiGate:

```
config system interface
    edit port5
        config ipv6
            set dhcp6-relay-service enable
        end
    end
```

```
        set dhcp6-relay-type regular
        set dhcp6-relay-ip 2000:db8:d0c::a
    end
next
end
```

IPv6 tunneling

IPv6 tunneling involves tunneling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. This is different than NAT because once the packet reaches its final destination, the true originating address of the sender is still readable. The IPv6 packets are encapsulated within packets with IPv4 headers that carry their IPv6 payload through the IPv4 network. IPv6 tunneling is suitable in networks that have completely transitioned over to IPv6 but need an internet connection, which is still mostly IPv4 addresses.

Both IPv6 tunneling devices, whether they are a host or a network device, must be dual stack compatible. The tunneling process is as follows:

1. The tunnel entry node creates an encapsulating IPv4 header and transmits the encapsulated packet.
2. The tunnel exit node receives the encapsulated packet.
3. The IPv4 header is removed.
4. The IPv6 header is updated and the IPv6 packet is processed.

There are two types of tunnels in IPv6 tunneling, automatic and configured. Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address. The IPv6 address of the destination host includes information about which IPv4 address the packet should be tunneled to. Configured tunnels are manually configured, and they are used for IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the tunnel endpoints must be specified.

Tunnel configurations

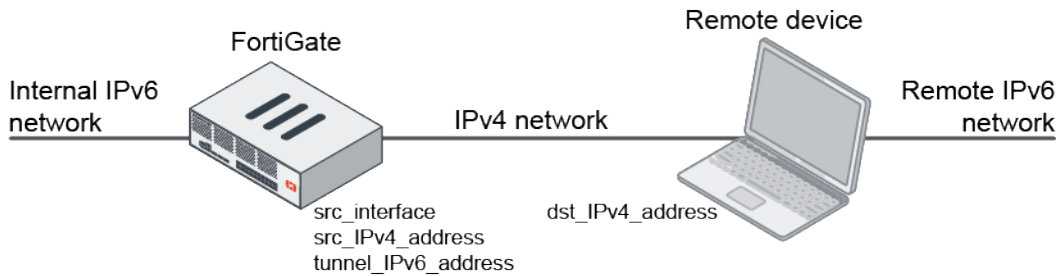

There are four tunneling configurations available depending on which segment of the path between the endpoints of the session the encapsulation takes place.

Type	Description
Network device-to-network device	Dual stack capable devices connected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. The tunnel spans one segment of the path taken by the IPv6 packets.
Host-to-network device	Dual stack capable hosts can tunnel IPv6 packets to an intermediary IPv6 or IPv4 network device that is reachable through an IPv4 infrastructure. The tunnel spans the first segment of the path taken by the IPv6 packets.
Host-to-host	Dual stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. The tunnel spans the entire path taken by the IPv6 packets.
Network device-to-host	Dual stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. The tunnel spans only the last segment of the path taken by the IPv6 packets.

Regardless of whether the tunnel starts at a host or a network device, the node that does the encapsulation needs to maintain soft state information, such as the maximum transmission unit (MTU), about each tunnel in order to process the IPv6 packets.

6in4 tunnel

The following tunnel configuration tunnels IPv6 traffic over an IPv4 network. An internal IPv6 interface can be configured under `config system` interface.

To configure an IPv6 tunnel over IPv4:

```

config system sit-tunnel
    edit <name>
        set source <src_IPv4_address>
        set destination <dst_IPv4_address>
        set interface <src_interface>
        set ip6 <tunnel_IPv6_address>
    next
end

```

4in6 tunnel

Conversely, the following tunnel configuration tunnels IPv4 traffic over an IPv6 network.

To configure an IPv4 tunnel over IPv6:

```

config system ipv6-tunnel
    edit <name>
        set source <src_IPv6_address>
        set destination <dst_IPv6_address>
        set interface <src_interface>
    next
end

```

The preceding configurations are not available in transparent mode.

IPv6 IPsec VPN

This topic describes how to configure the IPv6 IPsec VPN feature on your FortiGate device.

You can configure IPv6 using the CLI. To configure IPv6 using GUI, ensure IPv6 is enabled by going to *System > Feature Visibility* and enabling IPv6.

Overview

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes different ways IPv6 IPsec can be used:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors. See Site-to-site IPv4 over IPv6 VPN example on page 667 for sample configuration.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors. See Site-to-site IPv6 over IPv4 VPN example on page 676 for sample configuration.
IPv6 over IPv6	Both the VPN gateways and the protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors. See Site-to-site IPv6 over IPv6 VPN example on page 659 for sample configuration.

Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN:

Phase 1 and Phase 2 settings	The configuration is the same as for an IPv4 route-based VPN, except that <code>ip-version</code> is set to 6 and the <code>remote-gw6</code> keyword is used to specify an IPv6 remote gateway address. See Phase 1 configuration on page 1766 and Phase 2 configuration on page 1780 for more information.
Security policies	To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network's port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6. See VPN security policies on page 1784 for more information.
Routing	Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them: <ul style="list-style-type: none"> • You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. • You need a route to the remote protected network via the IPsec interface.

- You need a blackhole route to the remote protected network to ensure that IPsec traffic doesn't match the default route when the IPsec tunnel is down.

Routing is dependent on the method:

- **IPv4 over IPv6:** The route to the remote VPN gateway is an IPv6 route. The route to the remote protected network is an IPv4 route.
- **IPv6 over IPv4:** The route to the remote VPN gateway is an IPv4 route. The route to the remote protected network is an IPv6 route.
- **IPv6 over IPv6:** Routes to both the remote VPN gateway and the remote protected network are IPv6 routes.

You can create a new IPv6 static route from *Network > Static Routes*.

You can configure Phase 1 and Phase 2 settings from *VPN > IPsec Wizard*.

To configure Phase 1 and phase 2 settings:

1. Go to *VPN > IPsec Wizard*.
2. Enter a name and set *Template type* to *Custom*.
3. Click *Next*.
4. Under *Network*, set *IP Version* to *IPv6*.
5. Configure the rest of phase 1 and phase 2 settings as required and click *OK*.

IPv6 GRE tunnels

IPv6 addresses can be used at both ends of a GRE tunnel in the same way as with IPv4. See [GRE over IPsec on page 1811](#) for more information.

The configuration is similar to a tunnel for IPv4. However, when you configure the specific tunnel, you need to set the `ip-version` option to 6. This will enable IPv6-specific options for the tunnel.

To configure a GRE tunnel:

```
config system gre-tunnel
  edit <name of tunnel>
    set ip-version 6
    set remote-gw6 <IPv6 address of the remote gateway>
    set local-gw6 <IPv6 address of the local gateway>
  next
end
```

IPv6 tunnel inherits MTU based on physical interface

The MTU of an IPv6 tunnel interface is calculated from the MTU of its parent interface minus headers.

Example

In this topology, FortiGate B and FortiGate D are connected over an IPv6 network. An IPv6 tunnel is formed, and IPv4 can be used over the IPv6 tunnel. The tunnel interface MTU is based on the physical interface MTU minus the IP and TCP headers (40 bytes). On FortiGate B's physical interface port5, the MTU is set to 1320. The IPv6 tunnel is based on port5, and its MTU value of 1280 is automatically calculated from the MTU value of its physical interface minus the header. The same is true for port3 on FortiGate D.

To verify the MTU for the IPv6 tunnel on FortiGate B:

1. Configure port5:

```

config system interface
  edit "port5"
    set vdom "root"
    set type physical
    set snmp-index 7
    config ipv6
      set ip6-address 2000:172:16:202::1/64
      set ip6-allowaccess ping
    end
    set mtu-override enable
    set mtu 1320
  next
end

```

2. Configure the IPv6 tunnel:

```

config system ipv6-tunnel
  edit "B_2_D"
    set source 2000:172:16:202::1
    set destination 2000:172:16:202::2
    set interface "port5"
  next
end

```

3. Configure the tunnel interface:

```

config system interface
  edit "B_2_D"
    set vdom "root"
    set ip 172.16.210.1 255.255.255.255
    set allowaccess ping https http
    set type tunnel
    set remote-ip 172.16.210.2 255.255.255.255
    set snmp-index 33
    config ipv6
      set ip6-address 2000:172:16:210::1/64
      set ip6-allowaccess ping
      config ip6-extra-addr

```

```

        edit fe80::2222/10
        next
    end
end
set interface "port5"
next
end

```

4. Verify the interface lists:

```

# diagnose netlink interface list port5
if=port5 family=00 type=1 index=13 mtu=1320 link=0 master=0
ref=68 state=start present fw_flags=0 flags=up broadcast run multicast
Qdisc=mq hw_addr=**:**:**:**:**:** broadcast_addr=**:**:**:**:**:**
stat: rxp=1577 txp=1744 rxb=188890 txb=203948 rxe=0 txe=0 rxd=0 txd=0 mc=825 collision=0
@ time=1631647112
re: rxl=0 rxo=0 rxc=0 rxf=0 rxfi=0 rxm=0
te: txa=0 txc=0 txfi=0 txh=0 txw=0
misc rxc=0 txc=0
input_type=0 state=3 arp_entry=0 refcnt=68

# diagnose netlink interface list B_2_D
if=B_2_D family=00 type=769 index=41 mtu=1280 link=0 master=0
ref=25 state=start present fw_flags=0 flags=up p2p run noarp multicast
Qdisc=noqueue local=0.0.0.0 remote=0.0.0.0
stat: rxp=407 txp=417 rxb=66348 txb=65864 rxe=0 txe=61 rxd=0 txd=0 mc=0 collision=60 @
time=1631647126
re: rxl=0 rxo=0 rxc=0 rxf=0 rxfi=0 rxm=0
te: txa=0 txc=0 txfi=0 txh=0 txw=0
misc rxc=0 txc=0
input_type=0 state=3 arp_entry=0 refcnt=25

```

To verify the MTU for the IPv6 tunnel on FortiGate D:

1. Configure port3:

```

config system interface
    edit "port3"
        set vdom "root"
        set type physical
        set snmp-index 5
        config ipv6
            set ip6-address 2000:172:16:202::2/64
            set ip6-allowaccess ping
        end
        set mtu-override enable
        set mtu 1320
    next
end

```

2. Configure the IPv6 tunnel:

```

config system ipv6-tunnel
    edit "D_2_B"
        set source 2000:172:16:202::2
        set destination 2000:172:16:202::1
        set interface "port3"
    end
end

```

```

    next
end

```

3. Configure the tunnel interface:

```

config system interface
    edit "D_2_B"
        set vdom "root"
        set ip 172.16.210.2 255.255.255.255
        set allowaccess ping https http
        set type tunnel
        set remote-ip 172.16.210.1 255.255.255.255
        set snmp-index 36
        config ipv6
            set ip6-address 2000:172:16:210::2/64
            set ip6-allowaccess ping
            config ip6-extra-addr
                edit fe80::4424/10
                next
            end
        end
    end
    set interface "port3"
next
end

```

4. Verify the interface lists:

```

# diagnose netlink interface list port3

# diagnose netlink interface list D_2_B

```

Configuring IPv4 over IPv6 DS-Lite service

IPv4 over IPv6 DS-Lite service can be configured on a virtual network enabler (VNE) tunnel. In addition, VNE tunnel fixed IP mode supports username and password authentication.

```

config system vne-tunnel
    set status enable
    set mode {map-e | fixed-ip | ds-lite}
    set ipv4-address <IPv4_address>
    set br <IPv6_address or FQDN>
    set http-username <string>
    set http-password <password>
end

```

mode {map-e fixed-ip ds-lite}	Set the VNE tunnel mode: <ul style="list-style-type: none"> map-e: MAP-E fixed-ip: fixed IP ds-lite: DS-Lite
ipv4-address <IPv4_address>	Enter the tunnel IPv4 address and netmask. This setting is optional.
br <IPv6_address or FQDN>	Enter the IPv6 or FQDN of the border relay.
http-username <string>	Enter the HTTP authentication user name.
http-password <password>	Enter the HTTP authentication password.

DS-Lite allows applications using IPv4 to access the internet with IPv6. DS-Lite is supported by internet providers that do not have enough public IPv4 addresses for their customers, so DS-Lite is used for IPv6 internet connections. When a DS-Lite internet connections is used, the FortiGate encapsulates all data from IPv4 applications into IPv6 packets. The packets are then transmitted to the internet service provider using the IPv6 connection. Next, a dedicated server unpacks the IPv6 packets and forwards the IPv4 data to the actual destination on the internet.

DS-Lite example

In this example, DS-Lite VNE tunnel mode is used between the FortiGate and the BR.

To configure a DS-Lite tunnel between the FortiGate and the BR:

1. Configure the IPv6 interface:

```

config system interface
  edit "wan1"
    set vdom "root"
    set mode dhcp
    set allowaccess ping fgfm
    set type physical
    set role wan
    set snmp-index 1
    config ipv6
      set ip6-allowaccess ping
      set dhcp6-information-request enable
      set autoconf enable
      set unique-autoconf-addr enable
    end
  next
end

```

2. Configure the VNE tunnel:

```

config system vne-tunnel
  set status enable
  set interface "wan1"
  set ssl-certificate "Fortinet_Factory"
  set auto-asic-offload enable
  set ipv4-address 192.168.1.99 255.255.255.255
  set br "dgg.xxxxx.jp"
  set mode ds-lite
end

```

3. View the wan1 IPv6 configuration details:

```

config system interface
    edit "wan1"
        config ipv6
            get
                ip6-mode            : static
                nd-mode             : basic
                ip6-address         : 2001:f70:2880:xxxx:xxxx:xxxx:fe39:ccd2/64
                ip6-allowaccess     : ping
                icmp6-send-redirect : enable
                ra-send-mtu         : enable
                ip6-reachable-time  : 0
                ip6-retrans-time    : 0
                ip6-hop-limit       : 0
                dhcp6-information-request: enable
                cli-conn6-status    : 1
                vrrp-virtual-mac6   : disable
                vrip6_link_local    : ::
                ip6-dns-server-override: enable
                Acquired DNS1       : 2001:f70:2880:xxxx:xxxx:xxxx:fe40:9082
                Acquired DNS2       : ::
                ip6-extra-addr:
                ip6-send-adv        : disable
                autoconf            : enable
                prefix              : 2001:f70:2880:xxxx::/64
                preferred-life-time : 942735360
                valid-life-time     : 1077411840
                unique-autoconf-addr: enable
                interface-identifier: ::
                dhcp6-relay-service : disable
            end
        next
    end
end

```

4. Verify the IPv6 address list:

```

# diagnose ipv6 address list
dev=5 devname=wan1 flag= scope=0 prefix=64 addr=2001:f70:2880:xxxx:xxxx:xxxx:fe39:ccd2
preferred=11525 valid=13325 cstamp=6520 tstamp=6892
dev=5 devname=wan1 flag=P scope=253 prefix=64 addr=fe80::xxxx:xxxx:fe39:ccd2
preferred=4294967295 valid=4294967295 cstamp=6373 tstamp=6373
dev=18 devname=root flag=P scope=254 prefix=128 addr>:::1 preferred=4294967295
valid=4294967295 cstamp=3531 tstamp=3531
dev=25 devname=vsys_ha flag=P scope=254 prefix=128 addr>:::1 preferred=4294967295
valid=4294967295 cstamp=5604 tstamp=5604
dev=27 devname=vsys_fgfm flag=P scope=254 prefix=128 addr>:::1 preferred=4294967295
valid=4294967295 cstamp=6377 tstamp=6377

```

5. Test the tunnel connection by pinging the Google public DNS IPv6 address:

```
# execute ping6 2001:4860:4860::8888
PING 2001:4860:4860::8888 (2001:4860:4860::8888) 56 data bytes
64 bytes from 2001:4860:4860::8888: icmp_seq=1 ttl=114 time=6.89 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=2 ttl=114 time=3.39 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=3 ttl=114 time=3.46 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=4 ttl=114 time=3.34 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=5 ttl=114 time=3.39 ms
--- 2001:4860:4860::8888 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss, time 4079ms
rtt min/avg/max/mdev = 3.340/4.097/6.895/1.400 ms
```

Fixed IP mode example

In this example, fixed IP VNE tunnel mode with HTTP authentication is used between the FortiGate and the BR.

To configure a fixed IP mode with HTTP authentication between the FortiGate and the BR:**1. Configure the IPv6 interface:**

```
config system interface
  edit "wan1"
    set vdom "root"
    set mode dhcp
    set allowaccess ping fgfm
    set type physical
    set role wan
    set snmp-index 1
    config ipv6
      set ip6-allowaccess ping
      set dhcp6-information-request enable
      set autoconf enable
    end
  next
end
```

2. Configure the VNE tunnel:

```
config system vne-tunnel
  set status enable
  set interface "wan1"
  set ipv4-address 120.51.xxx.xxx1 255.255.255.255
  set br "2001:f60:xxxx:xxxx::1"
  set update-url "https://ddnsweb1.ddns.xxxxxx.jp/cgi-bin/ddns_
api.cgi?d=xxxxxx.v4v6.xxxxx.jp&p=*****&a=[IP6]&u=xxxxxx.v4v6.xxxxx.jp"
  set mode fixed-ip
  set http-username "laptop-1"
  set http-password *****
end
```

3. Verify the wan1 IPv6 configuration details:

```
config system interface
  edit "wan1"
    config ipv6
```

```
get
....
```

4. Verify the VNE daemon:

```
# diagnose test application vned 1
-----
vdom: root/0, is master, devname=wan1 link=0 tun=vne.root mode=fixed-ip ssl_
cert=Fortinet_Factory
end user ipv6 prefix: 2001:f70:2880:xxxx::/64
interface ipv6 addr: 2001:f70:2880:xxxx:xxxx:xxxx:fe39:ccd2
config ipv4 prefix: 120.51.xxx.xxx1/255.255.255.255
config br: 2001:f60:xxxx:xxxx::1
HTTP username: laptop-1
update url: https://ddnsweb1.ddns.xxxxxx.jp/cgi-bin/ddns_

```

IPv6 configuration examples

The following topics provide instructions on different IPv6 configuration examples:

- [IPv6 quick start example on page 652](#)
- [Site-to-site IPv6 over IPv6 VPN example on page 659](#)
- [Site-to-site IPv4 over IPv6 VPN example on page 667](#)
- [Site-to-site IPv6 over IPv4 VPN example on page 676](#)

IPv6 quick start example

In this example, a host belonging to a specific range on the internal IPv6 network can communicate exclusively with the web server and FTP server.

Additionally, all internal clients can access the Internet.

Prerequisites

Before you begin to configure IPv6, go through the following steps:

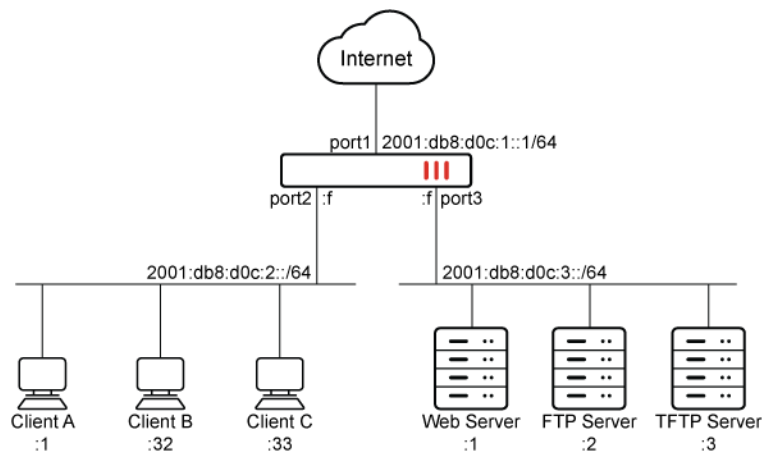

1. Obtain an IPv6 /48 global routing prefix, commonly known as a site prefix. To procure a 48-bit IPv6 site prefix for your organization simply liaise with your ISP.
2. Design a subnetting plan for your organization's IPv6 network using a 16-bit subnet ID, allowing for up to 65 535 subnets. The specific scheme will depend on the network's size, structure, and the organization's needs.

At this stage, the following installation and configuration conditions are assumed:

- You have administrative access to the GUI or CLI.
- The FortiGate unit is incorporated into your WAN or other networks, but for simplicity, only the standalone FortiGate configuration is displayed.

Topology

The following topology is used for this example:

- The company is assigned the site prefix of 2001:db8:d0c::/48 by their ISP.
- The IPv6 address for the Web Server is 2001:db8:d0c:3::1/64.
- The IPv6 address for the FTP Server is 2001:db8:d0c:3::2/64.
- The IPv6 address for the TFTP Server is 2001:db8:d0c:3::3/64.
- The range on the internal IPv6 network that can access both servers is from 2001:db8:d0c:2::1 to 2001:db8:d0c:2::32.
- The IPv6 address of port1 is 2001:db8:d0c:1::1/64.
- The IPv6 address of port2 is 2001:db8:d0c:2::f/64.
- The IPv6 address of port3 is 2001:db8:d0c:3::f/64.
- The IPv6 address of the default gateway is 2001:db8:d0c:1::f/64.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](#) for more information.

To configure the example in the GUI:

1. Configure the IPv6 address on port1, port2 and port3:
 - a. Go to *Network > Interfaces* and edit port1.
 - b. For *IPv6 addressing Mode*, select manual and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::1/64
----------------------------	----------------------

- c. Click OK.
- d. Repeat steps a and b for port2.

IPv6 Address/Prefix	2001:db8:d0c:2::f/64
----------------------------	----------------------

- e. Repeat steps a and b for port3.

IPv6 Address/Prefix	2001:db8:d0c:3::f/64
----------------------------	----------------------

2. Configure the default route:

- a. Go to *Network > Static Routes*.
- b. Click *Create New > IPv6 Static Route*.
- c. Configure the following settings:

Destination	::/0
Gateway Address	2001:db8:d0c:1::f
Interface	port1

- d. Select *OK*.

3. Configure the IPv6 firewall address for the Web Server:

- a. Go to *Policy & Objects > Addresses*.
- b. Select *Create New > Address*.
- c. Select *IPv6 Address* and fill out the fields with the following information:

Name	Web_Server
Type	IPv6 Subnet
IPv6 Address	2001:db8:d0c:3::1/128

- d. Select *OK*.

4. Configure the IPv6 firewall address for the FTP Server:

- a. Go to *Policy & Objects > Addresses*.
- b. Select *Create New > Address*.
- c. Select *IPv6 Address* and fill out the fields with the following information:

Name	FTP_Server
Type	IPv6 Subnet
IPv6 Address	2001:db8:d0c:3::2/128

- d. Select *OK*.

5. Configure the IPv6 address group, which includes both the Web and FTP servers:

- a. Go to *Policy & Objects > Addresses*.
- b. Select *Create New > Address Group*.
- c. Select *IPv6 Group* and fill out the fields with the following information:

Group name	Custom_Server
Members	Web_Server, FTP_Server

- d. Select *OK*.

6. Configure the IPv6 firewall address for the Internal IPv6 network range which can access both the Web and FTP server:

- a. Go to *Policy & Objects > Addresses*.
- b. Select *Create New > Address*.

- c. Select *IPv6 Address* and fill out the fields with the following information:

Name	Internal_Custom_Range
Type	IPv6 Range
IP Range	2001:db8:d0c:2::1 - 2001:db8:d0c:2::32

- d. Select *OK*.

7. Configure the IPv6 firewall policy to allow IPv6 traffic from *Internal_Custom_Range* to *Custom_Server*:

- a. Go to *Policy & Objects > Firewall Policy*.
- b. Click *Create New*.
- c. Name the policy and configure the following parameters:

Incoming Interface	port2
Outgoing Interface	port3
Source	Internal_Custom_Range
Destination	Custom_Server
Schedule	always
Service	FTP, HTTPS
Action	ACCEPT

- d. Click *OK*.

8. Configure the IPv6 firewall policy to allow IPv6 traffic from internal clients to the Internet:

- a. Go to *Policy & Objects > Firewall Policy*.
- b. Click *Create New*.
- c. Name the policy and configure the following parameters:

Incoming Interface	port2
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- d. Click *OK*.

To configure the example in the CLI:

1. Configure the IPv6 address on port1, port2, and port3:

```
config system interface
  edit "port1"
    config ipv6
```

```
        set ip6-address 2001:db8:d0c:1::1/64
    end
next
edit "port2"
    config ipv6
        set ip6-address 2001:db8:d0c:2::f/64
    end
next
edit "port3"
    config ipv6
        set ip6-address 2001:db8:d0c:3::f/64
    end
next
end
```

2. Configure the default route:

```
config router static6
    edit 0
        set gateway 2001:db8:d0c:1::f
        set device "port1"
    next
end
```

3. Configure the IPv6 firewall address for the Web Server:

```
config firewall address6
    edit "Web_Server"
        set ip6 2001:db8:d0c:3::1/128
    next
end
```

4. Configure the IPv6 firewall address for the FTP Server:

```
config firewall address6
    edit "FTP_Server"
        set ip6 2001:db8:d0c:3::2/128
    next
end
```

5. Configure the IPv6 address group, which includes for the Web and FTP Servers:

```
config firewall addrgrp6
    edit "Custom_Server"
        set member "FTP_Server" "Web_Server"
    next
end
```

6. Configure the IPv6 firewall address for the Internal IPv6 network range which can access both the Web and FTP Server:

```
config firewall address6
    edit "Internal_Custom_Range"
        set type iprange
        set start-ip 2001:db8:d0c:2::1
        set end-ip 2001:db8:d0c:2::32
    next
end
```

7. Configure the IPv6 firewall policy to allow IPv6 traffic from *Internal_Custom_Range* to *Custom_Server*:

```

config firewall policy
  edit 1
    set name "IPv6_internal_to_server"
    set srcintf "port2"
    set dstintf "port3"
    set action accept
    set srcaddr6 "Internal_Custom_Range"
    set dstaddr6 "Custom_Server"
    set schedule "always"
    set service "FTP" "HTTPS"
    set utm-status enable
    set logtraffic all
  next
end

```

8. Configure the IPv6 firewall policy to allow IPv6 traffic from Internal clients to the Internet:

```

config firewall policy
  edit 1
    set name "IPv6_internal_to_internet"
    set srcintf "port2"
    set dstintf "port1"
    set action accept
    set srcaddr6 "all"
    set dstaddr6 "all"
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set logtraffic all
  next
end

```

Verification

The following commands can be used to verify that IPv6 traffic is entering and leaving the FortiGate as expected. See [Debugging the packet flow on page 3314](#) for more information.

```

diagnose debug enable
diagnose debug flow trace start6 200

```

The output below indicates that hosts belonging to the *Internal_Custom_Range* can successfully reach both the *Web_Server* and *FTP_Server* defined in the *Custom_Server* address group.

However, they are unable to reach the TFTP server, as it is not included in the *Custom_Server* group. Furthermore, hosts with IPv6 addresses that do not belong to the *Internal_Custom_Range* are not able to access *Custom_Server*.

Host belonging to *Internal_Custom_Range* accessing *Web_Server*:

Site-to-site IPv6 over IPv6 VPN example

In this example, clients on IPv6-addressed networks communicate securely over public IPv6 infrastructure.

The following topology is used for this example:

- Port2 connects to the public network and port3 connects to the local network.
- The IPv6 address for HQ1 port2 and port3 is 2001:db8:d0c:1::e and 2001:db8:d0c:4::e, respectively.
- The IPv6 address for HQ2 port2 and port3 is 2001:db8:d0c:2::e and 2001:db8:d0c:3::e, respectively.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](#) for more information.

To configure the example in the GUI:

1. Configure the HQ1 FortiGate.

- Configure the IPv6 address on port2 and port3:
 - Go to *Network > Interfaces* and edit port2.
 - Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::e/64
----------------------------	----------------------

iii. Click *OK*.

iv. Repeat these steps for port3.

IPv6 Address/Prefix	2001:db8:d0c:4::e/64
----------------------------	----------------------

- Configure IPsec settings:

- Go to *VPN > IPsec Wizard* and enter a VPN name.
- Set *Template type* to *Custom*.
- Click *Next*.
- Configure the following *Network* settings:

IP Version	IPv6
-------------------	------

Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:2::e
Interface	port2

- v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

- vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

- c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:

- i. Go to *Policy & Objects > Firewall Policy*.
- ii. Click *Create New*.
- iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
 - i. Go to *Policy & Objects > Firewall Policy*.
 - ii. Click *Create New*.
 - iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

e. Configure the static routes:

- i. Go to *Network > Static Routes*.
- ii. Click *Create New > IPv6 Static Route*.
- iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	::/0
Gateway Address	2001:db8:d0c:1::f
Interface	port2

- iv. Select *OK*.
- v. Repeat the first two steps and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:3::/64
Interface	to_HQ2

- vi. Select *OK*.
- vii. Repeat the first two steps and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:3::/64
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

2. Configure the HQ2 FortiGate:

- a. Configure the IPv6 address on port2 and port3:
 - i. Go to *Network > Interfaces* and edit port2.
 - ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:2::e/64
----------------------------	----------------------

- iii. Click *OK*.
- iv. Repeat these steps for port3.

IPv6 Address/Prefix	2001:db8:d0c:3::e/64
----------------------------	----------------------

b. Configure IPsec settings:

- i. Go to *VPN > IPsec Wizard* and enter a VPN name.
- ii. Set *Template type* to *Custom*.
- iii. Click *Next*.
- iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:1::e

Interface	port2
------------------	-------

- v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

- vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

- c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:
- Go to *Policy & Objects > Firewall Policy*.
 - Click *Create New*.
 - Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- Click *OK*.
- d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
- Go to *Policy & Objects > Firewall Policy*.
 - Click *Create New*.
 - Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- Click *OK*.
- e. Configure the static routes:

- i. Go to *Network > Static Routes*.
- ii. Click *Create New > IPv6 Static Route*.
- iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	::/0
Gateway Address	2001:db8:d0c:2::f
Interface	port2

- iv. Select *OK*.
- v. Repeat the first two steps and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:4::/64
Interface	to_HQ1

- vi. Select *OK*.
- vii. Repeat the first two steps and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:4::/64
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.

- a. Configure the IPv6 address on port2 and port3:

```
config system interface
  edit port2
    config ipv6
      set ip6-address 2001:db8:d0c:1::e/64
    end
  next
  edit port3
    config ipv6
      set ip6-address 2001:db8:d0c:4::e/64
    end
  next
end
```

- b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
  edit "to_HQ2"
    set interface port2
    set ip-version 6
    set peertype any
    set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
    set remote-gw6 2001:db8:d0c:2::e
```

```

        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ2"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
        aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end

```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```

config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ2"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end

```

d. Configure the static routes:

```

config router static6
    edit 1
        set gateway 2001:db8:d0c:1::f
        set device "port2"
    next
    edit 2
        set dst 2001:db8:d0c:3::/64
        set device "to_HQ2"
    next
    edit 3
        set dst 2001:db8:d0c:3::/64
        set blackhole enable
        set distance 254
    next
end

```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and port3:

```
config system interface
  edit port2
    config ipv6
      set ip6-address 2001:db8:d0c:2::e/64
    end
  next
  edit port3
    config ipv6
      set ip6-address 2001:db8:d0c:3::e/64
    end
  next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
  edit "to_HQ1"
    set interface port2
    set ip-version 6
    set peertype any
    set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
    set remote-gw6 2001:db8:d0c:1::e
    set psksecret sample
  next
end
config vpn ipsec phase2-interface
  edit "to_HQ2"
    set phase1name "to_HQ1"
    set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
    set src-addr-type subnet6
    set dst-addr-type subnet6
  next
end
```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
  edit 1
    set srcintf "port3"
    set dstintf "to_HQ1"
    set srcaddr6 "all"
    set dstaddr6 "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic "all"
  next
  edit 2
    set srcintf "to_HQ1"
    set dstintf "port3"
    set srcaddr6 "all"
    set dstaddr6 "all"
    set action accept
    set schedule "always"
    set service "ALL"
```

```

        set logtraffic "all"
    next
end

```

d. Configure the static routes:

```

config router static6
    edit 1
        set gateway 2001:db8:d0c:2::f
        set device "port2"
    next
    edit 2
        set dst 2001:db8:d0c:4::/64
        set device "to_HQ1"
    next
    edit 3
        set dst 2001:db8:d0c:4::/64
        set blackhole enable
        set distance 254
    next
end

```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the diagnose vpn ike gateway list command on HQ1. The system should return the following:

```

vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 2001:db8:d0c:1::e:500 -> 2001:db8:d0c:2::e:500

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

The following topology is used for this example:

- Port2 connects to the IPv6 public network and port3 connects to the IPv4 local network.
- HQ1 port2 IPv6 address is 2001:db8:d0c:1::e and port3 IPv4 address is 192.168.2.1.
- HQ2 port2 IPv6 address is 2001:db8:d0c:2::e and port3 IPv4 address is 192.168.3.1.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](#) for more information.

To configure the example in the GUI:**1. Configure the HQ1 FortiGate.****a. Configure the IPv6 address on port2 and IPv4 address on port3:**

- i. Go to *Network > Interfaces* and edit port2.
- ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::e/64
----------------------------	----------------------

- iii. Click *OK*.
- iv. Go to *Network > Interfaces* and edit port3.
- v. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	192.168.2.1/24
-------------------	----------------

b. Configure IPsec settings:

- i. Go to *VPN > IPsec Wizard* and enter a VPN name.
- ii. Set *Template type* to *Custom*.
- iii. Click *Next*.
- iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:2::e
Interface	port2

v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

vi. Configure the following *New Phase 2* settings:

Local Address	addr_subnet
Remote Address	addr_subnet

c. Configure the IPv4 firewall policy to allow IPv4 traffic from port3 to the IPsec interface:

- i. Go to *Policy & Objects > Firewall Policy*.
- ii. Click *Create New*.

- iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

- d. Configure the IPv4 firewall policy to allow IPv4 traffic from the IPsec interface to port3:

- i. Go to *Policy & Objects > Firewall Policy*.
- ii. Click *Create New*.
- iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

- e. Configure the static routes:

- i. Go to *Network > Static Routes*.
- ii. Click *Create New > IPv6 Static Route*.
- iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	2001:db8:d0c:1::f
Interface	port2

- iv. Select *OK*.

- v. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the route to the remote protected network:

Destination	192.168.3.0/24
Interface	to_HQ2

- vi. Select *OK*.

- vii. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the blackhole route:

Destination	192.168.3.0/24
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

2. Configure the HQ2 FortiGate:

- a. Configure the IPv6 address on port2 and IPv4 address on port3:

- i. Go to *Network > Interfaces* and edit port2.
- ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:2::e/64
----------------------------	----------------------

- iii. Click *OK*.
- iv. Go to *Network > Interfaces* and edit port3.
- v. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	192.168.3.1/24
-------------------	----------------

- b. Configure IPsec settings:

- i. Go to *VPN > IPsec Wizard* and enter a VPN name.
- ii. Set *Template type* to *Custom*.
- iii. Click *Next*.
- iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:1::e
Interface	port2

- v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

- vi. Configure the following *New Phase 2* settings:

Local Address	addr_subnet
Remote Address	addr_subnet

- c. Configure the IPv4 firewall policy to allow IPv4 traffic from port3 to the IPsec interface:

- i. Go to *Policy & Objects > Firewall Policy*.
- ii. Click *Create New*.

- iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

- d. Configure the IPv4 firewall policy to allow IPv4 traffic from the IPsec interface to port3:

- i. Go to *Policy & Objects > Firewall Policy*.
- ii. Click *Create New*.
- iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

- e. Configure the static routes:

- i. Go to *Network > Static Routes*.
- ii. Click *Create New > IPv6 Static Route*.
- iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	2001:db8:d0c:2::f
Interface	port2

- iv. Select *OK*.

- v. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the route to the remote protected network:

Destination	192.168.2.0/24
Interface	to_HQ1

- vi. Select *OK*.

- vii. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the blackhole route:

Destination	192.168.2.0/24
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.

- a. Configure the IPv6 address on port2 and IPv4 address on port3:

```
config system interface
  edit port2
    config ipv6
      set ip6-address 2001:db8:d0c:1::e/64
    end
  next
  edit port3
    set ip 192.168.2.1/24
  next
end
```

- b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
  edit "to_HQ2"
    set interface port2
    set ip-version 6
    set peertype any
    set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
    set remote-gw6 2001:db8:d0c:2::e
    set psksecret sample
  next
end
config vpn ipsec phase2-interface
  edit "to_HQ2"
    set phase1name "to_HQ2"
    set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
    aes256gcm chacha20poly1305
    set src-addr-type subnet
    set dst-addr-type subnet
  next
end
```

- c. Configure the IPv4 firewall policy to allow IPv4 traffic between port3 to the IPsec interface:

```
config firewall policy
  edit 1
    set srcintf "port3"
    set dstintf "to_HQ2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
```

```
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
        set gateway 2001:db8:d0c:1::f
        set device "port2"
    next
end
config router static
    edit 1
        set dst 192.168.3.0 255.255.255.0
        set device "to_HQ2"
    next
    edit 2
        set dst 192.168.3.0 255.255.255.0
        set device blackhole
        set distance 254
    next
end
```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and IPv4 address on port3:

```
config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:2::e/64
        end
    next
    edit port3
        set ip 192.168.3.1/24
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ1"
        set interface port2
        set ip-version 6
        set peertype any
    end
end
```

```

        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:1::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet
        set dst-addr-type subnet
    next
end

```

c. Configure the IPv4 firewall policy to allow IPv4 traffic between port3 to the IPsec interface:

```

config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ1"
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end

```

d. Configure the static routes:

```

config router static6
    edit 1
        set gateway 2001:db8:d0c:2::f
        set device "port2"
    next
end
config router static
    edit 1
        set dst 192.168.2.0 255.255.255.0
        set device "to_HQ1"
    next
    edit 2
        set dst 192.168.2.0 255.255.255.0
        set device blackhole
        set distance 254
    next
end

```

```

        next
    end

```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```

vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 2001:db8:d0c:1::e:500 -> 2001:db8:d0c:2::e:500

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed networks communicate securely over IPv4 public infrastructure.

The following topology is used for this example:

- Port2 connects to the IPv4 public network and port3 connects to the IPv6 local network.
- HQ1 port2 IPv4 address is 10.0.0.1 and port3 IPv6 address is 2001:db8:d0c:4::e.
- HQ2 port2 IPv4 address is 10.0.1.1 and port3 IPv6 address is 2001:db8:d0c:3::e.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](#) for more information.

To configure the example in the GUI:

1. Configure the HQ1 FortiGate.

a. Configure the IPv4 address on port2 and IPv6 address on port3:

- Go to *Network > Interfaces* and edit port2.
- Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	10.0.0.1/24
-------------------	-------------

iii. Click OK.

iv. Go to *Network > Interfaces* and edit port3.

- Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:4::e/64
----------------------------	----------------------

b. Configure IPsec settings:

- Go to *VPN > IPsec Wizard* and enter a VPN name.
- Set *Template type* to *Custom*.
- Click *Next*.
- Configure the following *Network* settings:

IP Version	IPv4
Remote Gateway	Static IP Address
IP Address	10.0.1.1
Interface	port2

- v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

- vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

- c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:

- i. Go to *Policy & Objects > Firewall Policy*.
- ii. Click *Create New*.
- iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
 - i. Go to *Policy & Objects > Firewall Policy*.
 - ii. Click *Create New*.

- iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

- e. Configure the static routes:

- i. Go to *Network > Static Routes*.
- ii. Click *Create New > IPv4 Static Route*.
- iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	10.0.0.2
Interface	port2

- iv. Select *OK*.

- v. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:3::/64
Interface	to_HQ2

- vi. Select *OK*.

- vii. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:3::/64
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

2. Configure the HQ2 FortiGate:

- a. Configure the IPv4 address on port2 and IPv6 address on port3:
 - i. Go to *Network > Interfaces* and edit port2.
 - ii. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	10.0.1.1/24
-------------------	-------------

- iii. Click *OK*.

- iv. Go to *Network > Interfaces* and edit port3.
- v. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:3::e/64
----------------------------	----------------------

- b. Configure IPsec settings:
 - i. Go to *VPN > IPsec Wizard* and enter a VPN name.
 - ii. Set *Template type* to *Custom*.
 - iii. Click *Next*.
 - iv. Configure the following *Network* settings:

IP Version	IPv4
Remote Gateway	Static IP Address
IP Address	10.0.0.1
Interface	port2

- v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

- vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

- c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:
 - i. Go to *Policy & Objects > Firewall Policy*.
 - ii. Click *Create New*.
 - iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
 - i. Go to *Policy & Objects > Firewall Policy*.
 - ii. Click *Create New*.

- iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

- e. Configure the static routes:

- i. Go to *Network > Static Routes*.

- ii. Click *Create New > IPv4 Static Route*.

- iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	10.0.1.2
Interface	port2

- iv. Select *OK*.

- v. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:4::/64
Interface	to_HQ1

- vi. Select *OK*.

- vii. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:4::/64
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.

- a. Configure the IPv6 address on port2 and port3:

```
config system interface
  edit port2
    set ip 10.0.0.1/24
  next
```

```

    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:4::e/64
        end
    next
end

```

b. Configure IPsec settings:

```

config vpn ipsec phase1-interface
    edit "to_HQ2"
        set interface port2
        set ip-version 4
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw 10.0.1.1
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ2"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
        aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end

```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```

config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ2"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end

```

d. Configure the static routes:

```

config router static
    edit 1

```

```
        set gateway 10.0.0.2
        set device "port2"
    next
end
config router static6
    edit 1
        set dst 2001:db8:d0c:3::/64
        set device "to_HQ2"
    next
    edit 2
        set dst 2001:db8:d0c:3::/64
        set device blackhole
        set distance 254
    next
end
```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        set ip 10.0.1.1/24
    next
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:3::e/64
        end
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ1"
        set interface port2
        set ip-version 4
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw 10.0.0.1
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
        aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end
```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
```

```

        set dstintf "to_HQ1"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
edit 2
    set srcintf "to_HQ1"
    set dstintf "port3"
    set srcaddr6 "all"
    set dstaddr6 "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic "all"
next
end

```

d. Configure the static routes:

```

config router static
edit 1
    set gateway 10.0.1.2
    set device "port2"
next
end
config router static6
edit 1
    set dst 2001:db8:d0c:4::/64
    set device "to_HQ1"
next
edit 2
    set dst 2001:db8:d0c:4::/64
    set device blackhole
    set distance 254
next
end

```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```

vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 10.0.0.1:500 -> 10.0.0.2:500
tun_id: 10.0.0.2/::10.0.0.2
remote_location: 0.0.0.0
network-id: 0
created: 576319s ago
peer-id: 10.0.0.2
peer-id-auth: no

```

```
IKE SA: created 1/8  established 1/8  time 0/1127/9000 ms
IPsec SA: created 1/7  established 1/7  time 0/5/10 ms
```

```
id/spi: 8 c04ab0ead989f579/267813e164d4ec22
direction: initiator
status: established 59710-59710s ago = 0ms
proposal: aes128-sha256
key: 034a0c3bf3deb551-8d647af9b6f76578
lifetime/rekey: 86400/26389
DPD sent/rcv: 00000044/00000047
peer-id: 10.0.0.2
```

2. Run the diagnose vpn tunnel list command on HQ1. The system should return the following:

```
list all ipsec tunnel in vd 0
-----
name=to_HQ2 ver=1 serial=1 10.0.0.1:0->10.0.0.2:0 tun_id=10.0.0.2 tun_id6=:10.0.0.2

```

FortiGate LAN extension

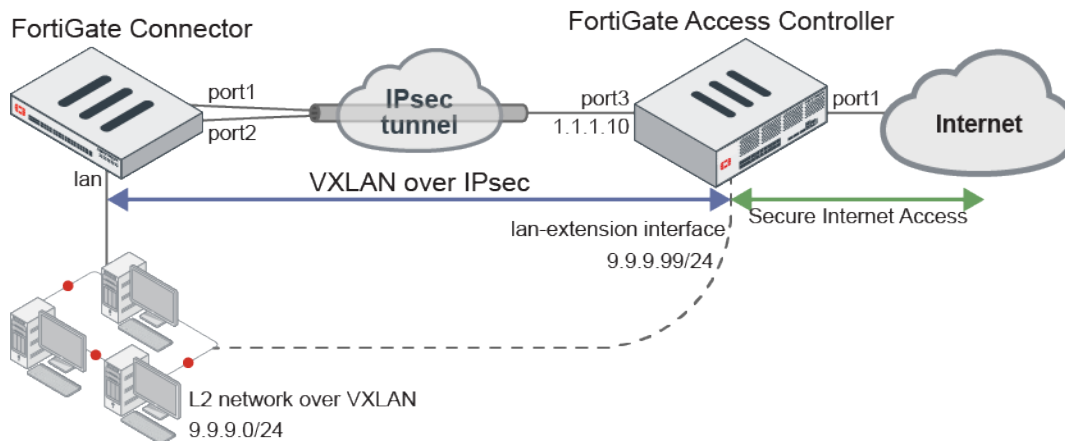

LAN extension mode allows a remote FortiGate to provide remote connectivity to a local FortiGate over a backhaul connection.

The remote FortiGate, called the FortiGate Connector, discovers the local FortiGate, called the FortiGate Controller, and forms one or more IPsec tunnels back to the FortiGate Controller. A VXLAN is established over the IPsec tunnels creating an L2 network between the FortiGate Controller and the network behind the FortiGate Connector.

In this example, the Controller provides secure internet access to the remote network behind the Connector. The Controller has two WAN connections: an inbound backhaul connection and an outbound internet connection. The Connector has two wired WAN/uplink ports that are connected to the internet.

After the Connector discovers the Controller and is authorized by the Controller, the Controller pushes a FortiGate LAN extension profile to the Connector. The Connector uses the profile configurations to form two IPsec tunnels back to the Controller. Additional VXLAN aggregate interfaces are automatically configured to create an L2 network between the Connector LAN port and a virtual LAN extension interface on the Controller. Clients behind the Connector can then connect to the internet through the Controller that is securing the internet connection.

To discover and authorize the FortiGate Controller:

1. On the FortiGate Controller:

- a. For high-end models (1000 series and higher), enable the FortiExtender setting:

```
config system global
    set fortiextender enable
end
```

This command is configured by default on low- and medium-end models (900 series and lower).

- b. Enable security fabric connections on port3 to allow the Connector to connect over CAPWAP:

```
config system interface
    edit "port3"
        set vdom "root"
        set ip 1.1.1.10 255.255.255.0
        set allowaccess fabric ping
    end
```

```

        set ip-managed-by-fortiipam enable
    next
end

```

2. On the FortiGate Connector:

a. Enable VDOMs:

```

config system global
    set vdom-mode multi-vdom
end

```

You will be logged out of the device when VDOM mode is enabled.

b. For high-end models (1000 series and higher), enable the FortiExtender setting in the global VDOM:

```

config global
    config system global
        set fortiextender enable
    end
end

```

This command is configured by default on low- and medium-end models (900 series and lower).

c. Create the lan-ext VDOM while setting the VDOM type to LAN extension (making the VDOM act as a FortiExtender in LAN extension mode), and add the Controller IP address:

```

config vdom
    edit lan-ext
        config system settings
            set vdom-type lan-extension
            set lan-extension-controller-addr "1.1.1.10"
            set ike-port 4500
        end
    next
end

```

d. Configure port1 and port2 to access the Controller:

```

config system interface
    edit "port1"
        set vdom "lan-ext"
        set ip 5.5.5.1 255.255.255.0
        set allowaccess ping fabric
        set type physical
        set lldp-reception enable
        set role wan
    next
    edit "port2"
        set vdom "lan-ext"
        set ip 6.6.6.1 255.255.255.0
        set allowaccess ping fabric
        set type physical
        set lldp-reception enable
        set role wan
    next
end

```

```

    next
end

```

3. On the FortiGate Controller:

a. Extension controller configurations are automatically initialized:

```

config extension-controller fortigate-profile
    edit "FGCONN-lanext-default"
        set id 0
        config lan-extension
            set ipsec-tunnel "fg-ipsec-XdSpij"
            set backhaul-interface "port3"
        end
    next
end

config extension-controller fortigate
    edit "FGT60E0000000001"
        set id "FG5H1E0000000001"
        set device-id 0
        set profile "FGCONN-lanext-default"
    next
end

```

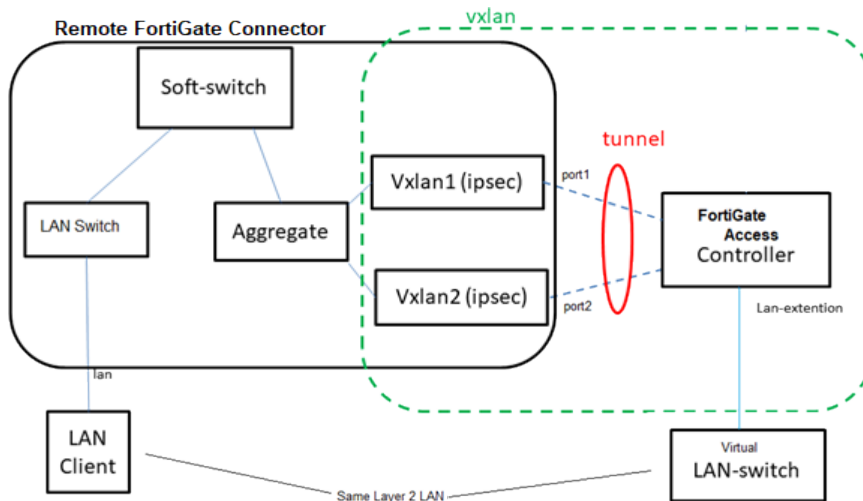

b. Enable FortiGate administration to authorize the Connector:

```

config extension-controller fortigate
    edit "FGT60E0000000001"
        set authorized enable
    next
end

```

4. After the FortiGate Connector has been authorized, the Controller pushes the IPsec tunnel configuration to the Connector, forcing it to establish the tunnel and form the VXLAN mechanism.

The VXLANs are built on the IPsec tunnels between the Connector and Controller. The VXLAN interfaces are aggregated for load balancing and redundancy. A softswitch combines the aggregate interface with the local LAN ports, allowing the LAN ports to be part of the VXLAN. This combines the local LAN ports with the virtual LAN extension interface on the FortiGate Controller.

- a. The Connector receives the IPsec configurations from the Controller, and creates tunnels for each uplink:

```
config vpn ipsec phase1-interface
  edit "ul-port1"
    set interface "port1"
    set ike-version 2
    set peertype any
    set net-device disable
    set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
    set localid "peerid-T4YLv2rp62SU6JhoCPIv02MzjLtS7P5HlxRER1Qpi6O9ZsAsbPSPvoiE"
    set dpd on-idle
    set comments "[FGCONN] Do NOT edit. Automatically generated by extension
controller."
    set remote-gw 1.1.1.10
    set psksecret *****
  next
  edit "ul-port2"
    set interface "port2"
    set ike-version 2
    set peertype any
    set net-device disable
    set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
    set localid "peerid-T4YLv2rp62SU6JhoCPIv02MzjLtS7P5HlxRER1Qpi6O9ZsAsbPSPvoiE"
    set dpd on-idle
    set comments "[FGCONN] Do NOT edit. Automatically generated by extension
controller."
    set remote-gw 1.1.1.10
    set psksecret *****
  next
end
```

- b. VXLAN interfaces are formed over each tunnel:

```
config system vxlan
  edit "vx-port1"
    set interface "ul-port1"
    set vni 1
    set dstport 9999
    set remote-ip "10.252.0.1"
  next
  edit "vx-port2"
    set interface "ul-port2"
    set vni 1
    set dstport 9999
    set remote-ip "10.252.0.1"
  next
end
```

- c. An aggregate interface is configured to load balance between the two VXLAN interfaces, using the source MAC and providing link redundancy:

```
config system interface
  edit "le-agg-link"
    set vdom "lan-ext"
    set type aggregate
    set member "vx-port1" "vx-port2"
    set snmp-index 35
    set lacp-mode static
```

```

        set algorithm Source-MAC
    next
end

```

- d. The softswitch bridges the aggregate interface and the local LAN to connect the LAN to the VXLAN bridged L2 network that goes to the FortiGate LAN extension interface:

```

config system switch-interface
    edit "le-switch"
        set vdom "lan-ext"
        set member "le-agg-link" "lan"
    next
end

```

- e. After the IPsec tunnel is setup and the VXLAN is created over the tunnel, the LAN extension interface is automatically created on the Controller:

```

config system interface
    edit "FGT60E0000000001"
        set vdom "root"
        set ip 192.168.0.254 255.255.255.0
        set allowaccess ping ssh
        set type lan-extension
        set role lan
        set snmp-index 27
        set ip-managed-by-fortiipam enable
        set interface "fg-ipsec-XdSpij"
    next
end

```

To configure the LAN extension interface and firewall policy on the FortiGate Controller:

1. Set the IP address and netmask of the LAN extension interface:

```

config system interface
    edit "FGT60E0000000001"
        set ip 9.9.9.99 255.255.255.0
        set ip-managed-by-fortiipam enable
    next
end

```

Devices on the remote LAN network will use this as their gateway.

2. Optionally, enable DHCP on the interface to assign IP addresses to the remote devices:

```

config system dhcp server
    edit 3
        set dns-service default
        set default-gateway 9.9.9.99
        set netmask 255.255.255.0
        set interface "FGT60E0000000001"
        config ip-range
            edit 1
                set start-ip 9.9.9.100
                set end-ip 9.9.9.254
            next
        end
        set dhcp-settings-from-fortiipam enable
    config exclude-range

```

```

        edit 1
            set start-ip 9.9.9.254
            set end-ip 9.9.9.254
        next
    end
next
end

```

3. Configure the firewall policy to allow traffic from the LAN extension interface to the WAN interface (port1):

```

config firewall policy
    edit "lan-ext"
        set name "qsaf"
        set srcintf "FGT60E0000000001"
        set dstintf "port1"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end

```

Optionally, security profiles and other settings can be configured.

The policy allows remote LAN clients to access the internet through the backhaul channel. Clients in the remote LAN behind the Connector receive an IP address over DHCP and access the internet securely through the Controller.

Diagnostics

Administrators can use the *Diagnostics* page to access the following tools:

Capture packet	Captures packet streams in real-time to let you view header and payload information. See Using the packet capture tool on page 690 .
Debug flow	Traces packet flow through FortiOS to help you diagnose and debug issues. See Using the debug flow tool on page 696 .

See also [Performing a sniffer trace or packet capture on page 3312](#) and [Debugging the packet flow on page 3314](#).

Using the packet capture tool

Administrators can use the packet capture tool to select a packet and view its header and payload information in real-time. Once completed, packets can be filtered by various fields or through the search bar. The capture can be saved as a PCAP file that you can use with a third-party application, such as Wireshark, for further analysis.

Recent capture criteria is saved after the packet capture, and you can select and use the same criteria again.

For information about running a packet capture in the CLI, see [Performing a sniffer trace or packet capture on page 3312](#).

To use the packet capture tool in the GUI:

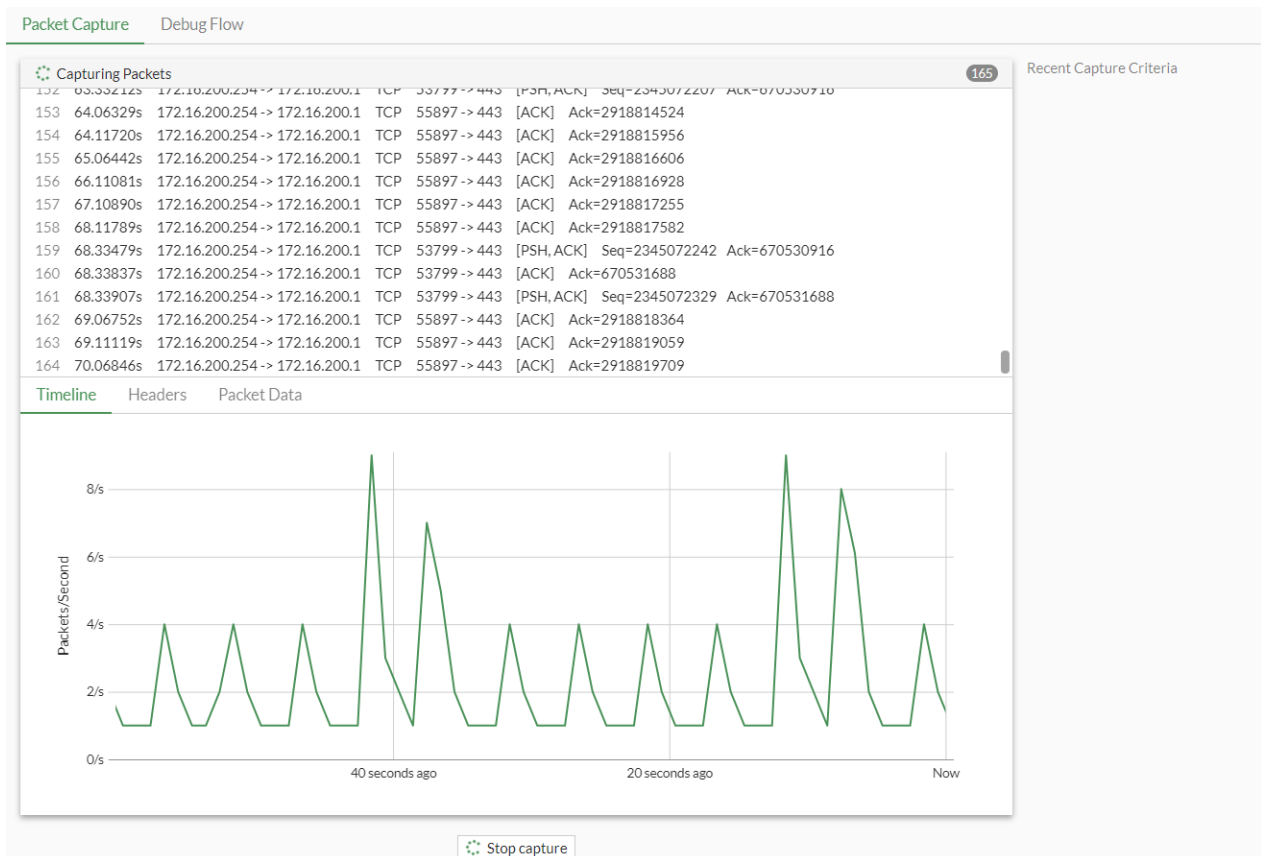

1. Go to *Network > Diagnostics* and select the *Packet Capture* tab.
2. Optionally, select an *Interface* (*any* is the default).
3. Optionally, enable *Filters* and select a *Filtering syntax*:
 - a. *Basic*: enter criteria for the *Host*, *Port*, and *Protocol number*.

The screenshot shows the 'Packet Capture' tab in the FortiOS GUI. At the top, there are two tabs: 'Packet Capture' (selected) and 'Debug Flow'. A blue information box at the top left states: 'NPU hardware acceleration must be disabled on the respective firewall policy to see all packets. To do so, set "auto-asic-offload" to "disable" in the CLI.' Below this, the 'Interface' is set to 'any' with a dropdown arrow. The 'Maximum captured packets' is set to 1 with a toggle switch. The 'Filters' section is expanded, showing 'Basic' as the selected filtering syntax. Under 'Basic', there are four input fields: 'Host', 'Port', 'Protocol number', and a '+' button for each. At the bottom, there is a green 'Start capture' button. On the right side, there is a section titled 'Recent Capture Criteria'.

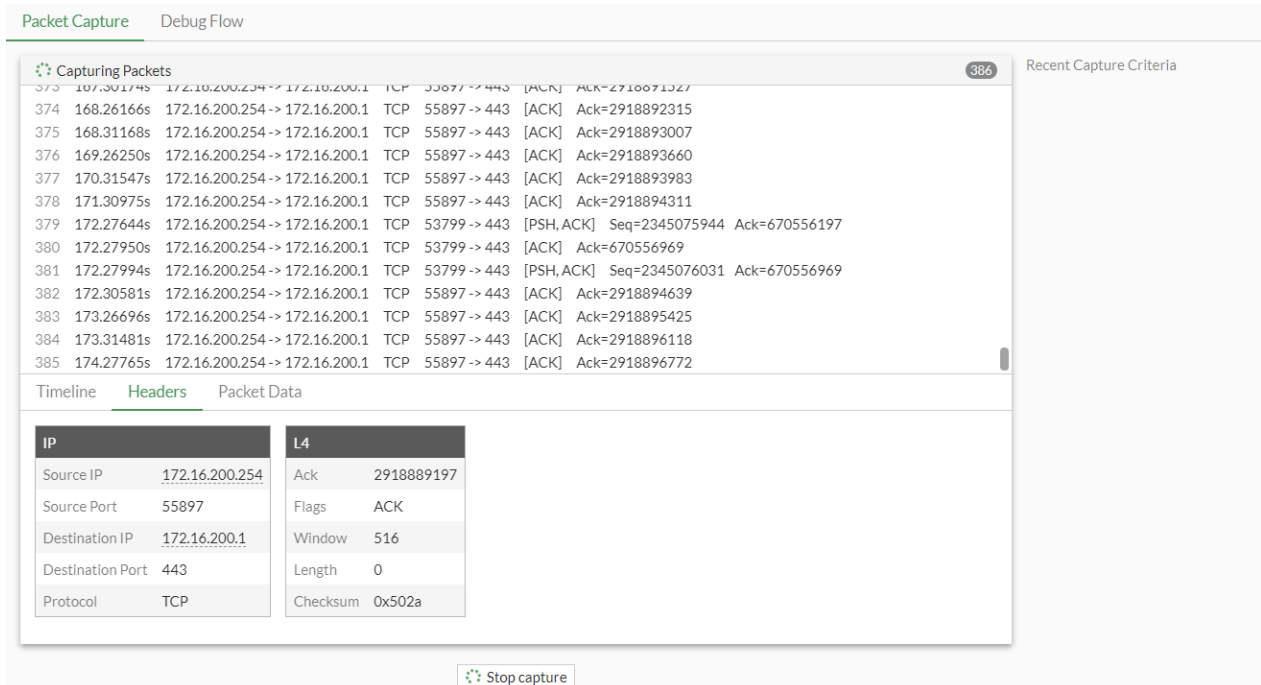

- b. *Advanced*: enter a string, such as *src host 172.16.200.254 and dst host 172.16.200.1 and dst port 443*.

The screenshot shows the 'Packet Capture' tab in the FortiOS GUI, similar to the previous one. The 'Interface' is still 'any' and 'Maximum captured packets' is 1. In the 'Filters' section, 'Advanced' is now the selected filtering syntax. Below 'Advanced', there is a single 'Filter' input field. At the bottom, there is a green 'Start capture' button. The 'Recent Capture Criteria' section is still visible on the right.

4. Click *Start capture*. The capture is visible in real-time.

5. While the capture is running, select a packet, then click the *Headers* or *Packet Data* tabs to view more information.

Back Save as pcap

7. Optionally, use the **Search** bar or the column headers to filter the results further.

The packet capture history is listed under **Recent Capture Criteria** in the right-side of the screen. Clicking the hyperlink will take you back to the main page with the interface and filter settings already populated.

For more granular sniffer output with various verbose settings, use `diagnose sniffer packet <interface> <'filter'> <verbose> <count> <tsformat>`. See [Performing a sniffer trace or packet capture on page 3312](#).

To use recent capture criteria:

1. Go to *Network > Diagnostics* and select the *Packet Capture* tab.
2. Under *Recent Capture Criteria*, click one of the saved capture criteria. The criteria populate the fields.
3. Click *Start Capture*.

Multiple packet captures

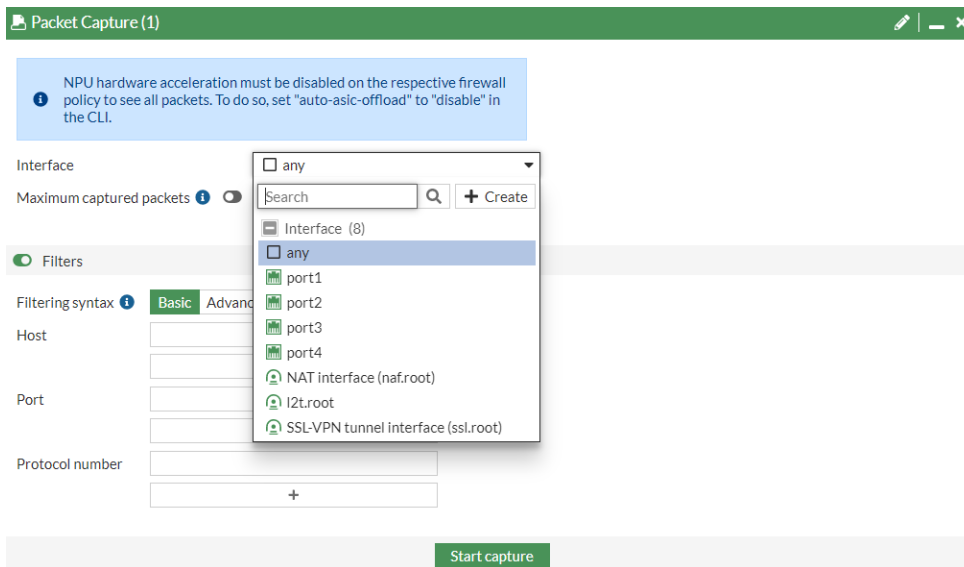

Multiple packet captures can be run simultaneously for when many packet captures are needed for one situation. For example, ingress and egress interfaces can be captured at the same time to compare traffic or the physical interface and VPN interface can be captured using different filters to see if packets are leaving the VPN.

The packet capture dialog can be docked and minimized to run in the background. The minimized dialog aligns with other CLI terminals that are minimized.

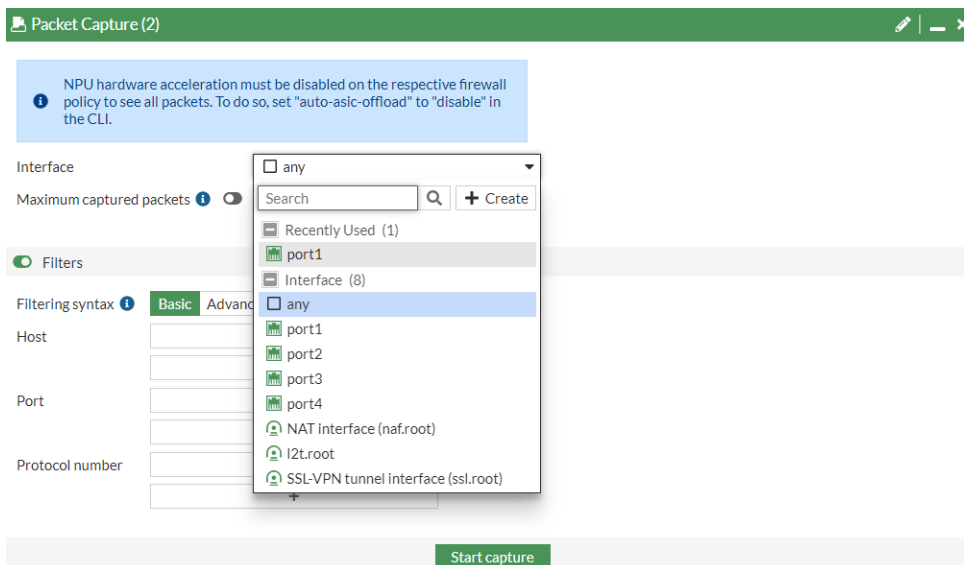

To run multiple packet captures at the same time:

1. Go to *Network > Diagnostics*.
2. Configure the first packet capture:

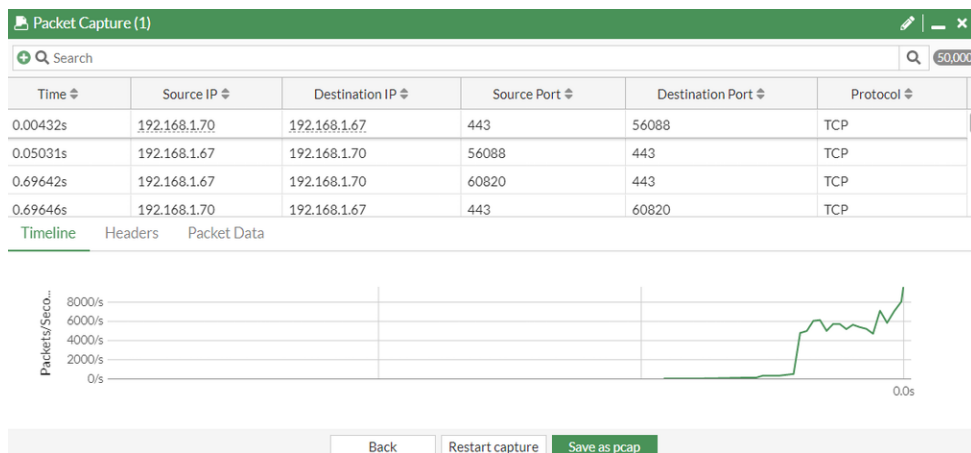

- a. Click **New packet capture**. The **Packet Capture (1)** dialog is displayed.

- b. Select the **Interface** and configure other settings as needed.
- c. Click **Start capture**. The first packet capture begins.
3. Minimize the packet capture. The packet capture continues to run.
4. Configure the second packet capture:
 - a. Click **New packet capture**. The **Packet Capture (2)** dialog is displayed.

- b. Select the **Interface** and configure other settings as needed.
- c. Click **Start capture**. The second packet capture begins.
5. When the captures are complete, expand the dialog and select **Save as pcap** for each packet capture.

Using the debug flow tool

Administrators can use the debug flow tool to display debug flow output in real-time until it is stopped. The completed output can be filtered by time, message, or function. The output can be exported as a CSV file.

For information about using the debug flow tool in the CLI, see [Debugging the packet flow on page 3314](#).

To run a debug flow:

1. Go to *Network > Diagnostics* and select the *Debug Flow* tab.
2. Optionally, enable *Filters* and select a *Filter type*:
 - a. **Basic:** filter by *IP address*, *Port*, and *Protocol*, which is the equivalent of:
 - # diagnose debug flow filter addr <addr/range>
 - # diagnose debug flow filter port <port/range>
 - # diagnose debug flow filter proto <protocol>

The screenshot shows the 'Debug Flow' configuration window. At the top, there is a 'Packet Capture' tab and a 'Debug Flow' tab (selected). Below the tabs is a blue information box with a warning icon and text: 'NPU hardware acceleration must be disabled on the respective firewall policy to see all packets. To do so, set "auto-asic-offload" to "disable" in the CLI.' Below this is a 'Number of packets' input field with the value '100'. Under the 'Filters' section, there is a 'Filter type' dropdown with 'Basic' selected and 'Advanced' as an option. Below that are 'IP type' (IPv4, IPv6), 'IP address' (input field), 'Port' (input field), and 'Protocol' (dropdown menu with 'Any' selected). At the bottom is a green 'Start debug flow' button. On the right side of the window, there is a 'Debug Flow' section with the text: 'Trace the flow of a packet through the FortiGate's various systems. Used for advanced diagnostics and debugging.'

- b. **Advanced:** filter by *Source IP*, *Source port*, *Destination IP*, *Destination port*, and *Protocol*, which is the equivalent of:

- # diagnose debug flow filter saddr <addr/range>
- # diagnose debug flow filter sport <port/range>
- # diagnose debug flow filter daddr <addr/range>
- # diagnose debug flow filter dport <port/range>
- # diagnose debug flow filter proto <protocol>

SD-WAN overview

SD-WAN is a software-defined approach to managing Wide-Area Networks (WAN). It consolidates the physical transport connections, or underlays, and monitors and load-balances traffic across the links. VPN overlay networks can be built on top of the underlays to control traffic across different sites.

Health checks and SD-WAN rules define the expected performance and business priorities, allowing the FortiGate to automatically and intelligently route traffic based on the application, internet service, or health of a particular connection.

WAN security and intelligence can be extended into the LAN by incorporating wired and wireless networks under the same domain. FortiSwitch and FortiAP devices integrate seamlessly with the FortiGate to form the foundation of an SD-Branch.

Some of the key benefits of SD-WAN include:

- Reduced cost with transport independence across MPLS, 4G/5G LTE, and others.
- Reduced complexity with a single vendor and single-pane-of-glass management.
- Improve business application performance thanks to increased availability and agility.
- Optimized user experience and efficiency with SaaS and public cloud applications.

SD-WAN components and design principles

SD-WAN can be broken down into three layers:

- Management and orchestration
- Control, data plane, and security
- Network access

The control, data plane, and security layer can only be deployed on a FortiGate. The other two layers can help to scale and enhance the solution. For large deployments, FortiManager and FortiAnalyzer provide the management and orchestration capabilities FortiSwitch and FortiAP provide the components to deploy an SD-Branch.

Layer	Functions	Devices	
Management and orchestration	<ul style="list-style-type: none"> Unified management Template based solution Zero touch provisioning Logging, monitoring, and analysis Automated orchestration using the REST API 	FortiManager 	FortiAnalyzer

Design principles

The [Five-pillar approach](#), described in the SD-WAN / SD-Branch Architecture for MSSPs guide, is recommended when designing a secure SD-WAN solution.

Underlay

Determine the WAN links that will be used for the underlay network, such as your broadband link, MPLS, 4G/5G LTE connection, and others.

For each link, determine the bandwidth, quality and reliability (packet loss, latency, and jitter), and cost. Use this information to determine which link to prefer, what type of traffic to send across the each link, and to help you the baselines for health-checks.

Overlay

VPN overlays are needed when traffic must travel across multiple sites. These are usually site-to-site IPsec tunnels that interconnect branches, datacenters, and the cloud, forming a hub-and-spoke topology.

The management and maintenance of the tunnels should be considered when determining the overlay network requirements. Manual tunnel configuration might be sufficient in a small environment, but could become unmanageable as the environment size increases. ADVPN can be used to help scale the solution; see [ADVPN on page 1933](#) for more information.

Routing

Traditional routing designs manipulate routes to steer traffic to different links. SD-WAN uses traditional routing to build the basic routing table to reach different destinations, but uses SD-WAN rules to steer traffic. This allows the steering to be based on criteria such as destination, internet service, application, route tag, and the health of the link. Routing in an SD-WAN solution is used to identify all possible routes across the underlays and overlays, which the FortiGate balances using ECMP.

In the most basic configuration, static gateways that are configured on an SD-WAN member interface automatically provide the basic routing needed for the FortiGate to balance traffic across the links. As the number of sites and destinations increases, manually maintaining routes to each destination becomes difficult. Using dynamic routing to advertise routes across overlay tunnels should be considered when you have many sites to interconnect.

Security

Security involves defining policies for access control and applying the appropriate protection using the FortiGate's NGFW features. Efficiently grouping SD-WAN members into SD-WAN zones must also be considered. Typically, underlays provide direct internet access and overlays provide remote internet or network access. Grouping the underlays together into one zone, and the overlays into one or more zones could be an effective method.

SD-WAN

The SD-WAN pillar is the intelligence that is applied to traffic steering decisions. It is comprised of four primary elements:

- **SD-WAN zones**

SD-WAN is divided into zones. SD-WAN member interfaces are assigned to zones, and zones are used in policies as source and destination interfaces. You can define multiple zones to group SD-WAN interfaces together, allowing logical groupings for overlay and underlay interfaces. Routing can be configured per zone.

See [SD-WAN members and zones on page 713](#).

- **SD-WAN members**

Also called interfaces, SD-WAN members are the ports and interfaces that are used to run traffic. At least one interface must be configured for SD-WAN to function.

See [Configuring the SD-WAN interface on page 704](#).

- **Performance SLAs**

Also called health-checks, performance SLAs are used to monitor member interface link quality, and to detect link failures. When the SLA falls below a configured threshold, the route can be removed, and traffic can be steered to different links in the SD-WAN rule.

SLA health-checks use active or passive probing:

- Active probing requires manually defining the server to be probed, and generates consistent probing traffic.
- Passive probing uses active sessions that are passing through firewall policies used by the related SD-WAN interfaces to derive health measurements. It reduces the amount of configuration, and eliminates probing traffic. See [Passive WAN health measurement on page 737](#) for details.

See [Performance SLA on page 725](#).

- **SD-WAN rules**

Also called services, SD-WAN rules control path selection. Specific traffic can be dynamically sent to the best link, or use a specific route.

Rules control the strategy that the FortiGate uses when selecting the outbound traffic interface, the SLAs that are monitored when selecting the outgoing interface, and the criteria for selecting the traffic that adheres to the rule. When no SD-WAN rules match the traffic, the implicit rule applies.

See [SD-WAN rules on page 766](#).

SD-WAN designs and architectures

The core functionalities of Fortinet's SD-WAN solution are built into the FortiGate. Whether the environment contains one FortiGate, or one hundred, you can use SD-WAN by enabling it on the individual FortiGates.

At a basic level, SD-WAN can be deployed on a single device in a single site environment:

At a more advanced level, SD-WAN can be deployed in a multi-site, hub and spoke environment:

At an enterprise or MSSP level, the network can include multiple hubs, possibly across multiple regions:

For more details, see the [SD-WAN / SD-Branch Architecture for MSSPs](#) guide.

SD-WAN quick start

This section provides an example of how to start using SD-WAN for load balancing and redundancy.

In this example, two ISP internet connections, wan1 (DHCP) and wan2 (static), use SD-WAN to balance traffic between them at 50% each.

1. [Configuring the SD-WAN interface on page 704](#)
2. [Adding a static route on page 706](#)
3. [Selecting the implicit SD-WAN algorithm on page 706](#)
4. [Configuring firewall policies for SD-WAN on page 707](#)
5. [Link monitoring and failover on page 707](#)
6. [Results on page 708](#)
7. [Configuring SD-WAN in the CLI on page 711](#)

Configuring the SD-WAN interface

First, SD-WAN must be enabled and member interfaces must be selected and added to a zone. The selected FortiGate interfaces can be of any type (physical, aggregate, VLAN, IPsec, and others), but must be removed from any other configurations on the FortiGate.

In this step, two interfaces are configured and added to the default SD-WAN zone (virtual-wan-link) as SD-WAN member interfaces. This example uses a mix of static and dynamic IP addresses; your deployment could also use only one or the other.

Once the SD-WAN members are created and added to a zone, the zone can be used in firewall policies, and the whole SD-WAN can be used in static routes.

To configure SD-WAN members:

1. Configure the wan1 and wan2 interfaces. See [Interface settings on page 163](#) for details.
 - a. Set the wan1 interface *Addressing mode* to *DHCP* and *Distance* to *10*.

By default, a DHCP interface has a distance of 5, and a static route has a distance of 10. It is important to account for this when configuring your SD-WAN for 50/50 load balancing by setting the DHCP interface's distance to 10.

- b. Set the wan2 interface *IP/Netmask* to *10.100.20.1 255.255.255.0*.
2. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
3. Set the *Interface* to *wan1*.
4. Leave *SD-WAN Zone* as *virtual-wan-link*.
5. As wan1 uses DHCP, leave *Gateway* set to *0.0.0.0*.

If IPv6 visibility is enabled in the GUI, an IPv6 gateway can also be added for each member. See [Feature visibility on page 2702](#) for details.

6. Leave *Cost* as *0*.

The *Cost* field is used by the Lowest Cost (SLA) strategy. The link with the lowest cost is chosen to pass traffic. The lowest possible *Cost* is *0*.

7. Set *Status* to *Enable*, and click *OK*.
8. Repeat the above steps for wan2, setting *Gateway* to the ISP's gateway: *10.100.20.2*.

Adding a static route

You must configure a default route for the SD-WAN. The default gateways for each SD-WAN member interface do not need to be defined in the static routes table. FortiGate will decide what route or routes are preferred using Equal Cost Multi-Path (ECMP) based on distance and priority.

To create a static route for SD-WAN:

1. Go to *Network > Static Routes*.
2. Click *Create New*. The *New Static Route* page opens.
3. Set *Destination* to *Subnet*, and leave the IP address and subnet mask as *0.0.0.0/0.0.0.0*.
4. In the *Interface* field select an SD-WAN zone.

5. Ensure that *Status* is *Enabled*.
6. Click *OK*.

Selecting the implicit SD-WAN algorithm

SD-WAN rules define specific routing options to route traffic to an SD-WAN member.

If no routing rules are defined, the default *Implicit* rule is used. It can be configured to use one of five different load balancing algorithms. See [Implicit rule on page 775](#) for more details and examples.

This example shows four methods to equally balance traffic between the two WAN connections. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and edit the *sd-wan* rule to select the method that is appropriate for your requirements.

- **Source IP** (CLI command: `source-ip-based`):
Select this option to balance traffic equally between the SD-WAN members according to a hash algorithm based on the source IP addresses.
- **Session** (weight-based):
Select this option to balance traffic equally between the SD-WAN members by the session numbers ratio among its members. Use weight 50 for each of the 2 members.
- **Source-Destination IP** (source-dest-ip-based):
Select this option to balance traffic equally between the SD-WAN members according to a hash algorithm based on the source and destination IP addresses.
- **Volume** (measured-volume-based):
Select this option to balance traffic equally between the SD-WAN members according to the bandwidth ratio among its members.

Configuring firewall policies for SD-WAN

SD-WAN zones can be used in policies as source and destination interfaces. Individual SD-WAN members cannot be used in policies.

You must configure a policy that allows traffic from your organization's internal network to the SD-WAN zone. Policies configured with the SD-WAN zone apply to all SD-WAN interface members in that zone.

To create a firewall policy for SD-WAN:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New*. The *New Policy* page opens.
3. Configure the following:

Name	Enter a name for the policy.
Incoming Interface	<i>internal</i>
Outgoing Interface	<i>virtual-wan-link</i>
Source	<i>all</i>
Destination	<i>all</i>
Schedule	<i>always</i>
Service	<i>ALL</i>
Action	<i>ACCEPT</i>
Firewall / Network Options	Enable <i>NAT</i> and set <i>IP Pool Configuration</i> to <i>Use Outgoing Interface Address</i> .
Security Profiles	Apply profiles as required.
Logging Options	Enable <i>Log Allowed Traffic</i> and select <i>All Sessions</i> . This allows you to verify results later.

4. Enable the policy, then click *OK*.

Link monitoring and failover

Performance SLA link monitoring measures the health of links that are connected to SD-WAN member interfaces by sending probing signals through each link to a server, and then measuring the link quality based on latency, jitter, and packet loss. If a link is broken, the routes on that link are removed and traffic is routed through other links. When the link is working again, the routes are re-enabled. This prevents traffic being sent to a broken link and lost.

In this example, the detection server IP address is 208.91.112.53. A performance SLA is created so that, if ping fails per the metrics defined, the routes to that interface are removed and traffic is detoured to the other interface. The ping protocol is used, but other protocols could also be selected as required.

To configure a performance SLA:

1. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Enter a name for the SLA and set *Protocol* to *Ping*.
3. In the *Server* field, enter the detection server IP address (208.91.112.53 in this example).
4. In the *Participants* field, select *Specify* and add wan1 and wan2.

SLA targets are not required for link monitoring.

5. Configure the required metrics in *Link Status*.
6. Ensure that *Update static route* is enabled. This disables static routes for the inactive interface and restores routes on recovery.
7. Click *OK*.

Results

The following GUI pages show the function of the SD-WAN and can be used to confirm that it is setup and running correctly:

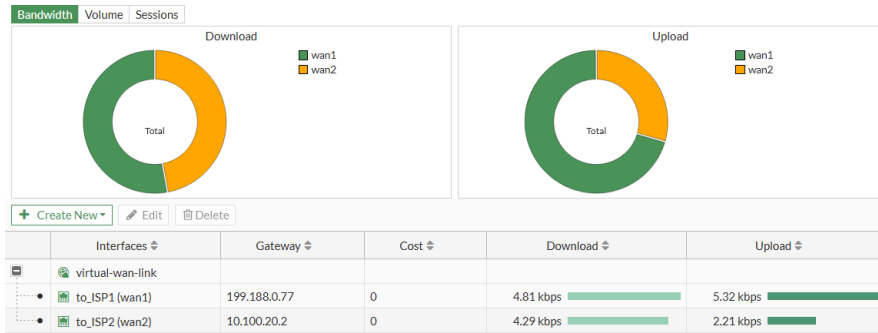

- [Interface usage on page 708](#)
- [Performance SLA on page 709](#)
- [Routing table on page 711](#)
- [Firewall policy on page 711](#)

Interface usage

Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab to review the SD-WAN interfaces' usage.

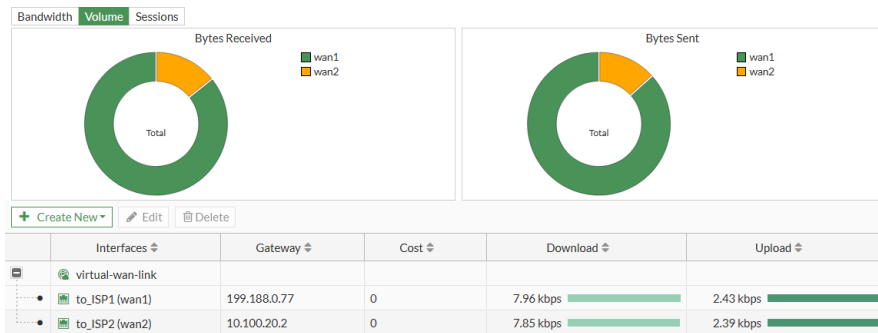

Bandwidth

Select **Bandwidth** to view the amount of downloaded and uploaded data for each interface.

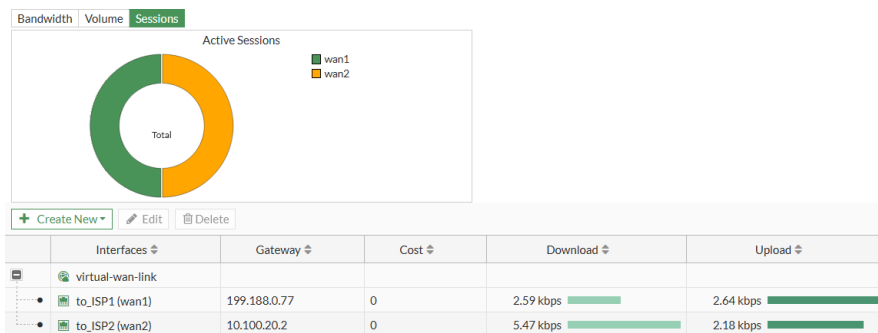

Volume

Select **Volume** to see donut charts of the received and sent bytes on the interfaces.

Sessions

Select **Sessions** to see a donut chart of the number of active sessions on each interface.

Performance SLA

Go to **Network > SD-WAN**, select the **Performance SLAs** tab, and select the SLA from the table (*server* in this example) to view the packet loss, latency, and jitter on each SD-WAN member in the health check server.

Packet loss

Select *Packet Loss* to see the percentage of packets lost for each member.

Latency

Select *Latency* to see the current latency, in milliseconds, for each member.

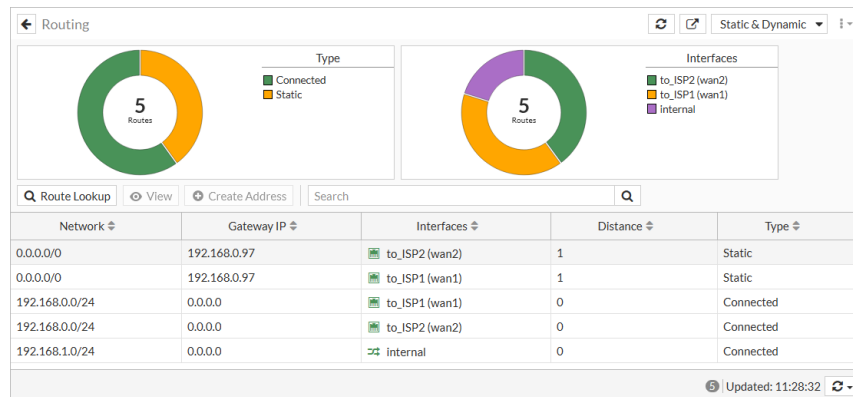

Jitter

Select *Jitter* to see the jitter, in milliseconds, for each member.

Routing table

Go to **Dashboard > Network**, expand the **Routing** widget, and select **Static & Dynamic** to review all static and dynamic routes. For more information about the widget, see [Static & Dynamic Routing monitor on page 115](#).

Firewall policy

Go to **Policy & Objects > Firewall Policy** to review the SD-WAN policy.

Configuring SD-WAN in the CLI

This example can be entirely configured using the CLI.

To configure SD-WAN in the CLI:

1. Configure the wan1 and wan2 interfaces:

```
config system interface
    edit "wan1"
        set alias to_ISP1
        set mode dhcp
        set distance 10
    next
    edit "wan2"
        set alias to_ISP2
        set ip 10.100.20.1 255.255.255.0
    next
end
```

2. Enable SD-WAN and add the interfaces as members:

```

config system sdwan
    set status enable
    config members
        edit 1
            set interface "wan1"
        next
        edit 2
            set interface "wan2"
            set gateway 10.100.20.2
        next
    end
end

```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

3. Create a static route for SD-WAN:

```

config router static
    edit 1
        set sdwan-zone "virtual-wan-link"
    next
end

```

4. Select the implicit SD-WAN algorithm:

```

config system sdwan
    set load-balance-mode {source-ip-based | weight-based | source-dest-ip-based |
measured-volume-based}
end

```

5. Create a firewall policy for SD-WAN:

```

config firewall policy
    edit <policy_id>
        set name <policy_name>
        set srcintf "internal"
        set dstintf "virtual-wan-link"
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set utm-status enable
        set ssl-ssh-profile <profile_name>
        set av-profile <profile_name>
        set webfilter-profile <profile_name>
        set dnsfilter-profile <profile_name>
        set emailfilter-profile <profile_name>
        set ips_sensor <sensor_name>
        set application-list <app_list>
        set voip-profile <profile_name>
        set logtraffic all
        set nat enable
    end
end

```

```

        set status enable
    next
end

```

6. Configure a performance SLA:

```

config system sdwan
    config health-check
        edit "server"
            set server "208.91.112.53"
            set update-static-route enable
            set members 1 2
        next
    end
end

```

Results

To view the routing table:

```

# get router info routing-table all

Routing table for VRF=0
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

S*      0.0.0.0/0 [1/0] via 172.16.20.2, wan1
          [1/0] via 10.100.20.2, wan2
C       10.100.20.0/24 is directly connected, wan2
C       172.16.20.2/24 is directly connected, wan1
C       192.168.0.0/24 is directly connected, internal

```

To diagnose the Performance SLA status:

```

FGT # diagnose sys sdwan health-check
Health Check(server):
Seq(1): state(alive), packet-loss(0.000%) latency(15.247), jitter(5.231) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(13.621), jitter(6.905) sla_map=0x0

```

SD-WAN members and zones

SD-WAN bundles interfaces together into zones. Interfaces are first configured as SD-WAN members. This does not change the interface, it just allows SD-WAN to reference the interface as a member. SD-WAN member interfaces can be any interface supported by FortiGates, such as physical ports, VLAN interfaces, LAGs, IPsec tunnels, GRE tunnels, IPsec tunnels, and FortiExtender interfaces. Once SD-WAN members are configured, they can be assigned to a zone. Zones are used in policies as source and destination interfaces, in static routes, and in SD-WAN rules.

Multiple zones can be used to group SD-WAN interfaces for logical scenarios, such as overlay and underlay interfaces. Using multiple zones in policies allows for more granular control over functions like resource access and UTM access. Individual SD-WAN member interfaces cannot be used directly in policies, but they can be moved between SD-WAN zones at any time. If a member interface requires a special SD-WAN consideration, it can be put into an SD-WAN zone by itself.

SD-WAN zones and members can be used in IPv4 and IPv6 static routes to make route configurations more flexible. SD-WAN zones and members can be used in SD-WAN rules to simplify the rule configuration. See [Specify an SD-WAN zone in static routes and SD-WAN rules on page 719](#) for more information.

When the Security Fabric is configured, SD-WAN zones are included in the Security Fabric topology views.

Topology

This topology is used in the following procedures:

- [Configuring SD-WAN member interfaces](#)
- [Configuring SD-WAN zones](#)
- [Using SD-WAN zones](#)

Configuring SD-WAN member interfaces

When configuring SD-WAN zones and members, it does not matter what order they are defined. In this example, the members are defined first, and they will be placed temporarily in the default zone called virtual-wan-link. A zone must be defined when creating a member, and the overlay and underlay zones will be created in the next procedure. It is standard practice to create SD-WAN members for each underlay and overlay interface, as most SD-WAN implementations apply SD-WAN intelligence to both underlay and overlay networks.

The following options can be configured for SD-WAN members:

GUI option	CLI option	Description
<i>Interface</i>	<code>interface</code>	Select the interface to use as an SD-WAN member. Optionally, select <i>None</i> in the GUI to not use an interface yet.
<i>SD-WAN Zone</i>	<code>zone</code>	Select the destination zone if it exists at the time of member creation. Otherwise, the default virtual-wan-link zone is applied. A new zone can be created within the GUI dropdown field.
<i>Gateway/IPv6 Gateway</i>	<code>gateway/gateway6</code>	Enter the default gateway for the interface. For interfaces that already have a default gateway, such as those configured using DHCP, this field is pre-populated in the GUI.
<i>Cost</i>	<code>cost</code>	Enter the cost of the interface for services in SLA mode (0 - 4294967295, default = 0). A lower cost has a higher preference.
<i>Priority</i>	<code>priority</code>	Enter the priority of the interface for IPv4 (1 - 65535, default = 1). The priority is used in the static route created for the SD-WAN member interface and in SD-WAN rules (including the implicit rule). When priority is used to determine the best route, the lower value takes precedence.
<i>Status</i>	<code>status</code>	Enable or disable the interface in SD-WAN.
<i>n/a</i>	<code>source/source6</code>	Set the source IP address used in the health check packet to the server.

To configure the SD-WAN members and add them to the default zone in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
2. Set the *Interface* to *WAN1*.
3. Leave the *SD-WAN Zone* as *virtual-wan-link*.

4. Click **OK**.
5. Repeat these steps to create SD-WAN members for the WAN2, VPN1, and VPN2 interfaces.

To configure the SD-WAN members and add them to the default zone in the CLI:

```

config system sdwan
  config members
    edit 1
      set interface "WAN1"
      set zone "virtual-wan-link"
    next
    edit 2
      set interface "WAN2"
      set zone "virtual-wan-link"
    next
    edit 3
      set interface "VPN1"
      set zone "virtual-wan-link"
    next
    edit 4
      set interface "VPN2"
      set zone "virtual-wan-link"
    next
  end
end

```

Configuring SD-WAN zones

While SD-WAN zones are primarily used to logically group interfaces that are often used for the same purpose (such as WAN1 and WAN2), sometimes an SD-WAN zone can have a single member. This is due to the constraint that SD-WAN members may not be referenced directly in policies; however, SD-WAN members can be referenced directly in SD-WAN rules.

In this example, two zones named Overlay and Underlay are configured, and the member interfaces are added to their respective zones.

To configure the SD-WAN zones in the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab.
2. Click *Create New > SD-WAN Zone*.
3. Enter the *Name*, *Underlay*.
4. Set the *Interface members* to *WAN1* and *WAN2*.

5. Click *OK*.
6. Repeat these steps to configure the *Overlay* zone with members *VPN1* and *VPN2*.

To configure the SD-WAN zones in the CLI:**1. Configure the SD-WAN zones:**

```
config system sdwan
  config zone
    edit "Overlay"
    next
    edit "Underlay"
    next
  end
end
```

2. Add the member interfaces to their respective zones:

```
config system sdwan
  config members
    edit 1
      set interface WAN1
      set zone "Underlay"
    next
    edit 2
      set interface WAN2
      set zone "Underlay"
    next
    edit 3
      set interface VPN1
      set zone "Overlay"
    next
    edit 4
      set interface VPN2
      set zone "Overlay"
    next
  end
end
```

In the `config zone` settings, there is a `service-sla-tie-break` parameter that includes three options for the tie-break method used when multiple interfaces in a zone are eligible for traffic:

- `cfg-order`: members that meet the SLA are selected in the order they are configured (default).
- `fib-best-match`: members that meet the SLA are selected that match the longest prefix in the routing table.
- `input-device`: members that meet the SLA are selected by matching the input device.

See [Overlay stickiness on page 998](#) for more information.

Using SD-WAN zones

Once SD-WAN zones are defined, they can be used in firewall policies. This section covers three policy scenarios:

- [Datacenter resource access](#)
- [Direct internet access](#)

- [Remote internet access](#)

SD-WAN zones are a critical component of SD-WAN rules. See [Fields for configuring WAN intelligence on page 771](#) for more information.

Datacenter resource access

Datacenter resources are made available through the VPN branches or overlay. In this example, there are two SD-WAN members in the overlay zone that the branch FortiGate can use to route traffic to and from the datacenter resource. The overlay zone is used as the destination in the firewall policy.

To configure the firewall policy:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	<i>DC_Access</i>
Incoming Interface	<i>LAN</i>
Outgoing Interface	<i>Overlay</i>
Source	<i>Branch_LAN</i>
Destination	<i>DC_LAN</i>
Action	<i>ACCEPT</i>

3. Configure the other settings as needed.
4. Click *OK*.

This firewall policy allows traffic to any interfaces included in the zone. The SD-WAN rules contain the intelligence used to select which members in the zone to use.

Direct internet access

Direct internet access (DIA) is how a branch may access resources contained on the public internet. This can be non-business resources (such as video streaming sites), or publically available business resources (such as vendor portals).

To configure the firewall policy:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	<i>DIA</i>
Incoming Interface	<i>LAN</i>

Outgoing Interface	<i>Underlay</i>
Source	<i>Branch_LAN</i>
Destination	<i>all</i>
Action	<i>ACCEPT</i>

3. Configure the other settings as needed.
4. Click *OK*.

Remote internet access

Remote internet access (RIA) is the ability for a branch location to route public internet access requests across the overlay and out one of the hub's (or datacenter's) WAN interfaces. This option is effective when a branch has a WAN circuit with a local ISP and a second circuit that is private, such as MPLS. When the WAN circuit goes down, it is possible to send traffic through the hub using the MPLS overlay.

To configure the firewall policy:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	<i>RIA</i>
Incoming Interface	<i>LAN</i>
Outgoing Interface	<i>Overlay</i>
Source	<i>Branch_LAN</i>
Destination	<i>all</i>
Action	<i>ACCEPT</i>

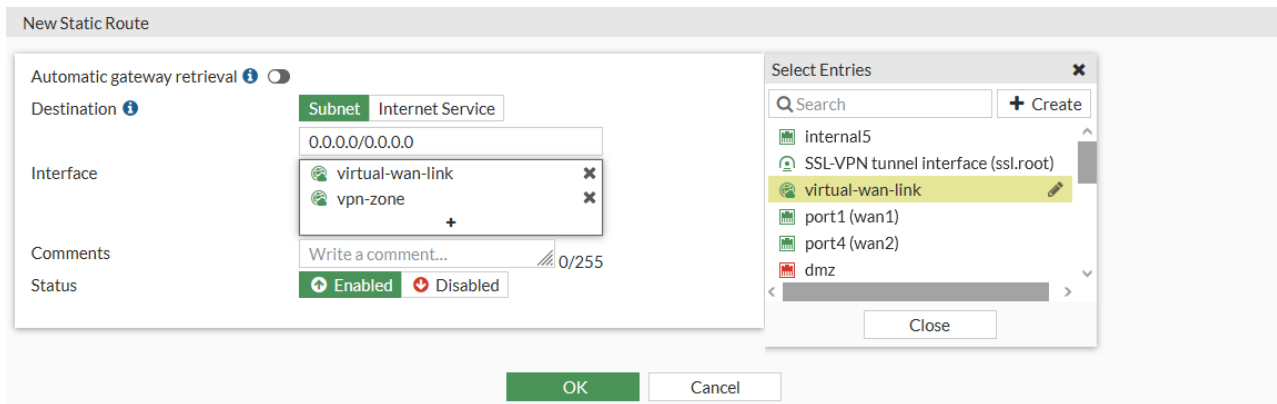

3. Configure the other settings as needed.
4. Click *OK*.

Specify an SD-WAN zone in static routes and SD-WAN rules

SD-WAN zones can be used in IPv4 and IPv6 static routes, and in SD-WAN service rules. This makes route configuration more flexible, and simplifies SD-WAN rule configuration.

To configure an SD-WAN zone in a static route in the GUI:

1. Go to *Network > Static Routes*
2. Edit an existing static route, or click *Create New* to create a new route.
3. Set *Interface* to one or more SD-WAN zones.

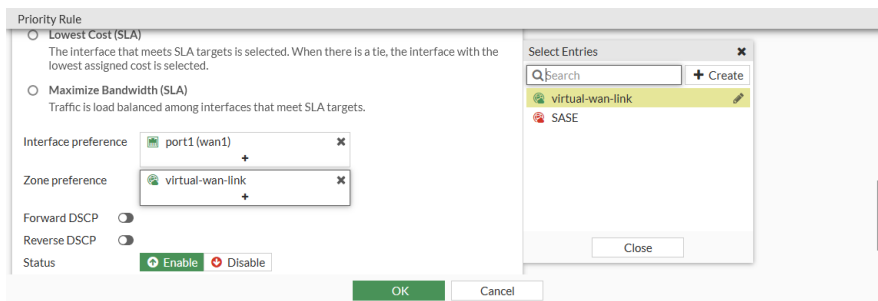

4. Configure the remaining settings are required.
5. Click OK.

To configure an SD-WAN zone in a static route in the CLI:

```
config router {static | static6}
  edit 1
    set sdwan-zone <zone> <zone> ...
  next
end
```

To configure an SD-WAN zone in an SD-WAN rule in the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab
2. Edit an existing rule, or click *Create New* to create a new rule.
3. In the *Zone preference* field add one or more SD-WAN zones.

4. Configure the remaining settings are needed.
5. Click OK.

To configure an SD-WAN zone in an SD-WAN rule in the CLI:

```
config system sdwan
  config service
    edit 1
      set priority-zone <zone>
    next
  end
end
```

Examples

In these two examples, three SD-WAN members are created. Two members, port13 and port15, are in the default zone (*virtual-wan-link*), and the third member, to_FG_B_root, is in the *SASE* zone.

Example 1

In this example:

- Two service rules are created. Rule 1 uses the *virtual-wan-link* zone, and rule 2 uses the *SASE* zone.
- Two IPv4 static routes are created. The first route uses the *virtual-wan-link* zone, and the second route uses the *SASE* zone.

To configure the SD-WAN:

1. Assign port13 and port15 to the *virtual-wan-link* zone and to_FG_B_root to the *SASE* zone:

```

config system sdwan
  set status enable
  config members
    edit 1
      set interface "port13"
      set zone "virtual-wan-link"
      set gateway 10.100.1.1
    next
    edit 2
      set interface "port15"
      set zone "virtual-wan-link"
      set gateway 10.100.1.5
    next
    edit 3
      set interface "to_FG_B_root"
      set zone "SASE"
    next
  end
end

```

2. Create two service rules, one for each SD-WAN zone:

```

config system sdwan
  config service
    edit 1
      set dst "10.100.20.0"
      set priority-zone "virtual-wan-link"
    next
  end
end

```

```

        edit 2
            set internet-service enable
            set internet-service-name "Fortinet-FortiGuard"
            set priority-zone "SASE"
        next
    end
end

```

3. Configure static routes for each of the SD-WAN zones:

```

config router static
    edit 1
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
    edit 2
        set dst 172.16.109.0 255.255.255.0
        set distance 1
        set sdwan-zone "SASE"
    next
end

```

To verify the results:

1. Check the service rule 1 diagnostics:

```

# diagnose sys sdwan service 1

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members(2):
    1: Seq_num(1 port13), alive, selected
    2: Seq_num(2 port15), alive, selected
Dst address(1):
    10.100.20.0-10.100.20.255

```

Both members of the *virtual-wan-link* zone are selected. In manual mode, the interface members are selected based on the member configuration order. In SLA and priority mode, the order depends on the link status. If all of the link statuses pass, then the members are selected based on the member configuration order.

2. Check the service rule 2 diagnostics:

```

# diagnose sys sdwan service 2

Service(2): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members(1):
    1: Seq_num(3 to_FG_B_root), alive, selected
Internet Service(1): Fortinet-FortiGuard(1245324,0,0,0)

```

The member of the *SASE* zone is selected.

3. Review the routing table:

```

# get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 10.100.1.1, port13
          [1/0] via 10.100.1.5, port15
S       172.16.109.0/24 [1/0] via 172.16.206.2, to_FG_B_root

```

The default gateway has the members from the *virtual-wan-link* zone, and the route to 172.16.10.9.0/24 has the single member from the *SASE* zone.

Example 2

In this example, two IPv6 static routes are created. The first route uses the *virtual-wan-link* zone, and the second route uses the *SASE* zone.

To configure the SD-WAN:

1. Configure port13 and port15 with IPv6 addresses and assign them to the *virtual-wan-link* zone, and assign to_FG_B_root to the *SASE* zone:

```
config system sdwan
  set status enable
  config members
    edit 1
      set interface "port13"
      set zone "virtual-wan-link"
      set gateway6 2004:10:100:1::1
      set source6 2004:10:100:1::2
    next
    edit 2
      set interface "port15"
      set zone "virtual-wan-link"
      set gateway6 2004:10:100:1::5
      set source6 2004:10:100:1::6
    next
    edit 3
      set interface "to_FG_B_root"
      set zone "SASE"
    next
  end
end
```

2. Configure IPv6 static routes for each of the SD-WAN zones:

```
config router static6
  edit 1
    set distance 1
    set sdwan-zone "virtual-wan-link"
  next
  edit 2
    set dst 2003:172:16:109::/64
    set distance 1
    set sdwan-zone "SASE"
  next
end
```

To verify the results:

1. Review the routing table:

```
# get router info6 routing-table static
Routing table for VRF=0
S*      ::/0 [1/0] via 2004:10:100:1::1, port13, 00:20:51, [1024/0]
```

```

[1/0] via 2004:10:100:1::5, port15, 00:20:51, [1024/0]
S      2003:172:16:109::/64 [1/0] via ::ac10:ce02, to_FG_B_root, 00:20:51, [1024/0]
S      2003:172:16:209::/64 [5/0] via ::ac10:ce02, to_FG_B_root, 14:40:14, [1024/0]

```

The IPv6 default route includes the members from the *virtual-wan-link* zone, and the route to 2003:172:16:109::/64 has the single member from the *SASE* zone.

Defining a preferred source IP for local-out egress interfaces on SD-WAN members

The preferred source IP can be configured on SD-WAN members so that local-out traffic is sourced from that IP. In the following example, two SD-WAN members (port5 and port6) will use loopback1 and loopback2 as sources instead of their physical interface address. A static route is created for destination 200.0.0.0/24 to use the virtual-wan-link. In turn, the FortiGate will create two ECMP routes to the member gateways and source the traffic from the loopback IPs.

To configure preferred source IPs for SD-WAN members:

1. Configure the SD-WAN members and other settings:

```

config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "port5"
            set gateway 10.100.1.1
            set preferred-source 1.1.1.1
            set source 1.1.1.1
        next
        edit 2
            set interface "port7"
            set gateway 10.100.1.5
            set preferred-source 1.1.1.2
            set source 1.1.1.2
        next
    end
end

```

In the SD-WAN `config members` settings, configuring the `source` for the health check probes is still required. SD-WAN adds dedicated kernel routes (`proto=17`) for the health checks using the interface IP or source IP when specified. To view the kernel routes, use `diagnose ip route list`.

2. Configure the static route:

```
config router static
  edit 2000
    set dst 200.0.0.0 255.255.255.0
    set distance 1
    set sdwan-zone "virtual-wan-link"
  next
end
```

To verify the configuration:**1. Verify the kernel routing table for 200.0.0.0/24:**

```
# get router info kernel | grep -A 2 200.0.0.0/24
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->200.0.0.0/24 pref=0.0.0.0
  gwy=10.100.1.1 flag=14 hops=255 oif=13(port5) pref=1.1.1.1
  gwy=10.100.1.5 flag=14 hops=254 oif=15(port7) pref=1.1.1.2
```

2. Verify the routing table for 200.0.0.0/24:

```
# get router info routing-table details 200.0.0.0/24
Routing table for VRF=0
Routing entry for 200.0.0.0/24
  Known via "static", distance 1, metric 0, best
  * vrf 0 10.100.1.1, via port5, prefsrc 1.1.1.1
  * vrf 0 10.100.1.5, via port7, prefsrc 1.1.1.2
```

3. Run a sniffer trace after some traffic passes.**a. When traffic leaves port5:**

```
# diagnose sniffer packet any "host 200.0.0.1" 4
interfaces=[any]
filters=[host 200.0.0.1]
6.592488 port5 out 1.1.1.1 -> 200.0.0.1: icmp: echo request
7.592516 port5 out 1.1.1.1 -> 200.0.0.1: icmp: echo request
8.592532 port5 out 1.1.1.1 -> 200.0.0.1: icmp: echo request
```

b. When traffic leaves port7:

```
# diagnose sniffer packet any "host 200.0.0.1" 4
interfaces=[any]
filters=[host 200.0.0.1]
75.664173 port7 out 1.1.1.2 -> 200.0.0.1: icmp: echo request
76.664194 port7 out 1.1.1.2 -> 200.0.0.1: icmp: echo request
```

Traffic exiting each interface is sourced from the corresponding loopback IP.

Performance SLA

Performance SLAs are used to measure the health of links that are connected to SD-WAN member interfaces by either sending probing signals through each link to a server, or using session information that is captured by firewall policies (see [Passive WAN health measurement on page 737](#) for information), and measuring the link quality based on latency, jitter, and packet loss. If a link fails all of the health checks, the routes on that link are removed from the SD-WAN link

load balancing group, and traffic is routed through other links. When the link passes SLA, the routes are reestablished. This prevents traffic from being sent to a broken link and getting lost.

The following topics provide instructions on configuring performance SLA:

- [Performance SLA overview on page 726](#)
- [Link health monitor on page 731](#)
- [Monitoring performance SLA on page 733](#)
- [Passive WAN health measurement on page 737](#)
- [Passive health-check measurement by internet service and application on page 743](#)
- [Mean opinion score calculation and logging in performance SLA health checks on page 746](#)
- [Embedded SD-WAN SLA information in ICMP probes on page 749](#)
- [SD-WAN application monitor using FortiMonitor on page 757](#)
- [Classifying SLA probes for traffic prioritization on page 761](#)

Performance SLA overview

Performance SLAs consist of three parts:

- [Health checks](#)
- [SLA targets](#)
- [Link status](#)

Health checks

A health check is defined by a [probe mode](#), [protocol](#), and [server](#). These three options specify what resource is being evaluated and how the evaluation is done. Each health check should be configured specifically for that resource, so the probe mode, protocol and server should be tailored for the particular service. For example, the health check for a VoIP service will differ than one for a database replication service.

Performance SLA participants are the interfaces that will be evaluated for a given health check. They must be SD-WAN member interfaces, but do not have to belong to the same zone. When selecting participants, only select participants that you expect the service communications to use. For example, a health check for a corporate resource might only use the overlay to access the service. Therefore, you would only add the VPN interfaces as participants.

There are six predefined performance SLA profiles for newly created VDOMs or factory reset FortiGate devices: AWS, DNS, FortiGuard, Gmail, Google Search, and Office 365. These performance SLA profiles provide Fortinet recommended settings for common services. To complete the performance SLA configuration, add the participants for the service. You can adjust the default settings to suit your needs.

Bandwidth limits and traffic prioritization can be enabled using SLA probe classification. The `class-id` command can be used to assign a class ID to SLA probes. Class IDs then guarantee that assigned bandwidth is honored when traffic congestion occurs. See [Classifying SLA probes for traffic prioritization on page 761](#).

Probe mode

The probe mode can be set to active, passive, or prefer passive.

In active mode, the FortiGate sends a packet of the type specified by the protocol setting towards the defined server. This allows you to evaluate the path to the destination server using the protocol that matches the service provided by the server. Active probing does add some overhead in the form of health check probes (and additional configurations to define the probe type and server), but it has the benefit of constantly measuring the performance of the path to the server. This can be beneficial when reviewing historical data.

In passive mode, session information captured by firewall policies is used to determine latency, jitter, and packet loss. This has the added benefit of not generating additional traffic, and does not require the performance SLA to define a specific server for measurement. Instead, the SD-WAN rule must define the traffic to evaluate, and the firewall policy permitting the traffic must have a setting enabled. See [Passive WAN health measurement on page 737](#) and [Passive health-check measurement by internet service and application on page 743](#) for more information.

Prefer passive mode is a combination of active and passive modes. Health is measured using traffic when there is traffic, and using probes when there is no traffic. A protocol and server must be configured.

Protocol

Health checks support a variety of protocols and protocol specific options. The most commonly used protocols (ping, HTTP, and DNS) can be configured in the GUI when creating a new performance SLA on the *Network > SD-WAN > Performance SLAs* page. The following protocols and options can be configured in the CLI using the `set protocol <option>` parameter:

ping	Use PING to test the link with the server.
tcp-echo	Use TCP echo to test the link with the server.
udp-echo	Use UDP echo to test the link with the server.
http	Use HTTP-GET to test the link with the server.
twamp	Use TWAMP to test the link with the server.
dns	Use DNS query to test the link with the server. The FortiGate sends a DNS query for an A Record and the response matches the expected IP address.
tcp-connect	Use a full TCP connection to test the link with the server. The method to measure the quality of the TCP connection can be: <ul style="list-style-type: none"> <code>half-open</code>: FortiGate sends SYN and gets SYN-ACK. The latency is based on the round trip between SYN and SYN-ACK (default). <code>half-close</code>: FortiGate sends FIN and gets FIN-ACK. The latency is based on the round trip between FIN and FIN-ACK.
ftp	Use FTP to test the link with the server. The FTP mode can be: <ul style="list-style-type: none"> <code>passive</code>: The FTP health-check initiates and establishes the data connection (default). <code>port</code>: The FTP server initiates and establishes the data connection.

SD-WAN health checks can generate traffic that becomes quite high as deployments grow. Take this into consideration when setting DoS policy thresholds. For details on setting DoS policy thresholds, refer to [DoS policy on page 1212](#).

To use UDP-echo and TCP-echo as health checks:

```
config system sdwan
  set status enable
  config health-check
    edit "h4_udp1"
      set protocol udp-echo
      set port 7
      set server <server>
    next
    edit "h4_tcp1"
      set protocol tcp-echo
      set port 7
      set server <server>
    next
    edit "h6_udp1"
      set addr-mode ipv6
      set server "2032::12"
      set protocol udp-echo
      set port 7
    next
  end
end
```

To use DNS as a health check, and define the IP address that the response must match:

```
config system sdwan
  set status enable
  config health-check
    edit "h4_dns1"
      set protocol dns
      set dns-request-domain "ip41.forti2.com"
      set dns-match-ip 1.1.1.1
    next
    edit "h6_dns1"
      set addr-mode ipv6
      set server "2000::15.1.1.4"
      set protocol dns
      set port 53
      set dns-request-domain "ip61.xxx.com"
    next
  end
end
```

To use TCP Open (SYN/SYN-ACK) and TCP Close (FIN/FIN-ACK) to verify connections:

```
config system sdwan
  set status enable
  config health-check
    edit "h4_tcpconnect1"
      set protocol tcp-connect
      set port 443
      set quality-measured-method {half-open | half-close}
      set server <server>
    next
    edit "h6_tcpconnect1"
```

```

        set addr-mode ipv6
        set server "2032::13"
        set protocol tcp-connect
        set port 444
        set quality-measured-method {half-open | half-close}
    next
end
end

```

To use active or passive mode FTP to verify connections:

```

config system sdwan
    set status enable
    config health-check
        edit "h4_ftp1"
            set protocol ftp
            set port 21
            set user "root"
            set password *****
            set ftp-mode {passive | port}
            set ftp-file "1.txt"
            set server <server>
        next
        edit "h6_ftp1"
            set addr-mode ipv6
            set server "2032::11"
            set protocol ftp
            set port 21
            set user "root"
            set password *****
            set ftp-mode {passive | port}
            set ftp-file "2.txt"
        next
    end
end

```

Health check probe packets support DSCP markers for accurate link performance evaluation for high priority applications. This allows the probe packet to match the real traffic it is providing measurements for, including how that traffic is shaped by upstream devices based on the DSCP markers.

To mark health check packets with DSCP:

```

config system sdwan
    config health-check
        edit <name>
            set diffservcode <6-bits_binary, 000000-111111>
            set protocol <option>
        next
    end
end

```

Server

An IP address or FQDN can be defined as the server that the probe packets will be sent to. Up to two servers can be defined this way. When two servers are provided, both must fail in order for the health check to fail. This is to avoid a

scenario where one remote server is down and causes a false positive that the link is down. The FortiGate can still use the interface associated with this health check to reach the remaining healthy server.

The purpose of the server is not simply to measure the health of the link, but rather the health of the path to a resource. It is highly recommended to use an IP address or FQDN that reflects the resource so the traffic path is considered.

A server can only be used in one performance SLA at any given time.

SLA targets

SLA targets are a set of constraints that are used in SD-WAN rules to control the paths that traffic takes. The constraints are:

- Latency threshold: latency for SLA to make a decision, in milliseconds (0 - 10000000, default = 5).
- Jitter threshold: jitter for SLA to make a decision, in milliseconds (0 - 10000000, default = 5).
- Packet loss threshold: packet loss for SLA to make a decision, in percentage (0 - 100, default = 0).

These settings should be specific to the service whose performance is being considered. You should attempt to configure the constraints to be just under the maximum values for the application or service to function well. For example, if your application requires less than 100 ms latency, then you should configure the SLA target to be 90 ms. Misconfiguring these settings will cause the performance SLA to lose value. If the values are too tight, then you may have traffic flipping between links before necessary. If the values are too loose, then performance may be impacted and the FortiGate will do nothing about it.

In the GUI, one SLA target can be configured, but additional targets can be configured in the CLI. Once a second target is configured in the CLI, additional targets can be configured from the GUI. Multiple SLA targets can be configured where a server provides multiple services that have different values for acceptable performance. For example, Google provides a DNS service and entertainment services (YouTube), so it is necessary to configure multiple SLA targets in this case since you can only configure a server in one performance SLA.

Link status

The *Link Status* section of the performance SLA configuration consists of three settings that determine the frequency that the link is evaluated, and the requirements to be considered valid or invalid:

- *Check interval*: the interval in which the FortiGate checks the interface, in milliseconds (500 - 3600000, default = 500).
- *Failures before inactive*: the number of failed status checks before the interface shows as inactive (1 - 3600, default = 5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links.
- *Restore link after*: the number of successful status checks before the interface shows as active (1 - 3600, default = 5). This setting also helps prevent flapping.

When a participant becomes inactive, the performance SLA causes the FortiGate to withdraw all static routes associated with that interface. If there are multiple static routes using the same interface, they will all be withdrawn when the link monitor is failing.

Link health monitor

Performance SLA link health monitoring measures the health of links that are connected to SD-WAN member interfaces by either sending probing signals through each link to a server, or using session information that is captured on firewall policies (see [Passive WAN health measurement on page 737](#) for information), and measuring the link quality based on latency, jitter, and packet loss. If a link fails all of the health checks, the routes on that link are removed from the SD-WAN link load balancing group, and traffic is routed through other links. When the link is working again the routes are reestablished. This prevents traffic being sent to a broken link and lost.

When an SD-WAN member has multiple health checks configured, all of the checks must fail for the routes on that link to be removed from the SD-WAN link load balancing group.

Two health check servers can be configured to ensure that, if there is a connectivity issue, the interface is at fault and not the server. A server can only be used in one health check.

The FortiGate uses the first server configured in the health check server list to perform the health check. If the first server is unavailable, then the second server is used. The second server continues to be used until it becomes unavailable, and then the FortiGate returns to the first server, if it is available. If both servers are unavailable, then the health check fails.

You can configure the protocol that is used for status checks, including: Ping, HTTP, DNS, TCP echo, UDP echo, two-way active measurement protocol (TWAMP), TCP connect, and FTP. In the GUI, only Ping, HTTP, and DNS are available.

You can view link quality measurements by going to *Network > SD-WAN* and selecting the *Performance SLAs* tab. The table shows the default health checks, the health checks that you configured, and information about each health check. The values shown in the *Packet Loss*, *Latency*, and *Jitter* columns are for the health check server that the FortiGate is currently using. The green up arrows indicate that the server is responding, and does not indicate if the health checks are being met. See [Results on page 708](#) for more information.

To configure a link health monitor in the GUI:

1. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Set a *Name* for the SLA.
3. If enabled in Feature Visibility, set the *IP Version*. *IPv6* does not support all of the protocols.
4. Set the *Probe mode*:
 - *Active*: Send probes to determine link quality.
 - *Passive*: Use traffic to determine link quality. Enable passive health checks in policies to allow measurement.
 - *Prefer Passive*: Same as passive mode, but send probes when there is no traffic.
5. Set the *Protocol* that you need to use for status checks: *Ping*, *HTTP*, or *DNS*.
6. Set *Server* to the IP addresses of up to two servers that all of the SD-WAN members in the performance SLA can reach. If the *Protocol* is *DNS*, set the *DNS Server* to either the same as the system DNS, or specify the primary and secondary DNS servers.
7. Set *Participants* to *All SD-WAN Members*, or select *Specify* to choose specific SD-WAN members.
8. Set *Enable probe packets* to enable or disable sending probe packets.
9. Configure *SLA Target*:

If the health check is used in an SD-WAN rule that uses *Manual* or *Best Quality* strategies, enabling *SLA Target* is optional. If the health check is used in an SD-WAN rule that uses *Lowest Cost (SLA)* or *Maximum Bandwidth (SLA)* strategies, then *SLA Target* is enabled.

When *SLA Target* is enabled, configure the following:

- **Latency threshold:** Calculated based on last 30 probes (default = 5ms).
- **Jitter threshold:** Calculated based on last 30 probes (default = 5ms).
- **Packet Loss threshold:** Calculated based on last 100 probes (default = 0%).

10. In the **Link Status** section configure the following:

- **Check interval:** The interval in which the FortiGate checks the interface, in milliseconds (500 - 3600000, default = 500).
- **Failures before inactive:** The number of failed status checks before the interface shows as inactive (1 - 3600, default = 5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links
- **Restore link after:** The number of successful status checks before the interface shows as active (1 - 3600, default = 5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links

11. In the **Actions when Inactive** section, enable **Update static route** to disable static routes for inactive interfaces and restore routes when interfaces recover.

The screenshot shows the 'New Performance SLA' configuration window in the FortiGate GUI. The 'Link Status' section is expanded, showing the following settings:

- Check interval:** 500 ms
- Failures before inactive:** 5
- Restore link after:** 5 check(s)

The 'Actions when Inactive' section is also expanded, showing the 'Update static route' option enabled (indicated by a green checkmark).

The 'Additional Information' sidebar on the right contains the following links:

- API Preview
- Performance SLA Setup Guides
- Link Monitoring
- SLA Targets
- Online Guides
- Relevant Documentation
- Video Tutorials
- Hot Questions at FortiAnswers

12. Click **OK**.

To configure a link health monitor in the CLI:

```
config system sdwan
config health-check
edit "PingSLA"
set addr-mode {ipv4 | ipv6}
set server <server1_IP_address> <server2_IP_address>
set detect-mode {active | passive | prefer-passive}
set protocol {ping | tcp-echo | udp-echo | http | twamp | dns | tcp-connect |
ftp}

set ha-priority <integer>
set probe-timeout <integer>
set probe-count <integer>
set probe-packets {enable | disable}
set interval <integer>
set failtime <integer>
set recoverytime <integer>
```

```

set diffservcode <binary>
set update-static-route {enable | disable}
set update-cascade-interface {enable | disable}
set sla-fail-log-period <integer>
set sla-pass-log-period <integer>
set threshold-warning-packetloss <integer>
set threshold-alert-packetloss <integer>
set threshold-warning-latency <integer>
set threshold-alert-latency <integer>
set threshold-warning-jitter <integer>
set threshold-alert-jitter <integer>
set vrf <integer>
set source <ip address>
set members <member_number> ... <member_number>
config sla
    edit 1
        set link-cost-factor {latency jitter packet-loss}
        set latency-threshold <integer>
        set jitter-threshold <integer>
        set packetloss-threshold <integer>
    next
end
next
end
end

```

Additional settings are available for some of the protocols:

Protocol	Additional options
http	port <port_number> http-get <url> http-agent <string> http-match <response_string>
twamp	port <port_number> security mode {none authentication} password <password> packet-size <size>
ftp	ftp-mode {passive port} ftp-file <path>

For more examples see [Protocol](#).

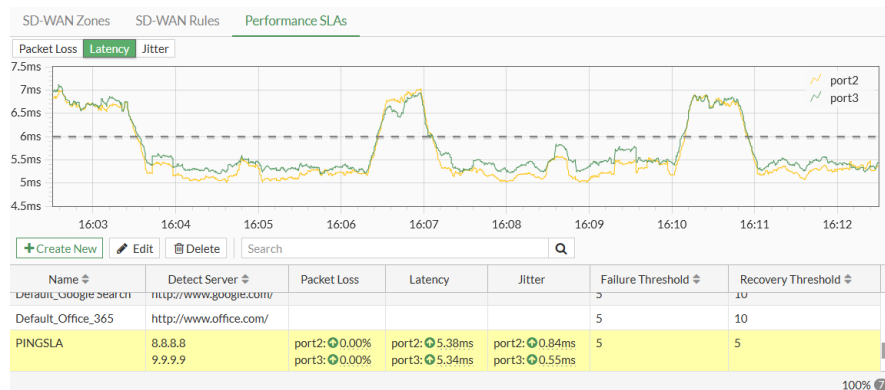

Monitoring performance SLA

SD-WAN diagnostics can be used to help maintain your SD-WAN solution.

Monitoring SD-WAN link quality status

Link quality plays a significant role in link selection for SD-WAN. Investigate any prolonged issues with packet loss, latency, or jitter to ensure that your network does not experience degraded performance or an outage.

You can monitor the link quality status of SD-WAN interface members by going to *Network > SD-WAN* and selecting the *Performance SLAs* tab.

The live charts show the packet loss, latency, or jitter for the selected health check. Hover the cursor over a line in the chart to see the specific value for that interface at that specific time.

The table shows information about each health check, including the configured servers, link quality data, and thresholds. The colored arrow indicates the status of the interface when the last status check was performed: green means that the interface was active, and red means that the interface was inactive. Hover the cursor over the arrow for additional information.

Monitoring system event logs

The features adds an SD-WAN daemon function to keep a short, 10 minute history of SLA that can be viewed in the CLI.

Performance SLA results related to interface selection, session failover, and other information, can be logged. These logs can then be used for long-term monitoring of traffic issues at remote sites, and for reports and views in FortiAnalyzer.

The time intervals that Performance SLA fail and pass logs are generated in can be configured.

To configure the fail and pass logs' generation time interval:

```
config system sdwan
  config health-check
    edit "PingSLA"
      set sla-fail-log-period 30
      set sla-pass-log-period 60
    next
  end
end
```

To view the 10 minute Performance SLA link status history:

```
FGDocs # diagnose sys sdwan sla-log PingSLA 1
Timestamp: Fri Sep 4 10:32:37 2020, vdom root, health-check PingSLA, interface: wan2,
status: up, latency: 4.455, jitter: 0.430, packet loss: 0.000%.

```

In the FortiAnalyzer GUI:

Monitoring using the REST API

SLA log and interface information can be monitored using the REST API. This feature is also used by FortiManager as part of its detailed SLA monitoring and drilldown features.

API call	URL
Interface log	https://172.172.172.9/api/v2/monitor/virtual-wan/interface-log
SLA log	https://172.172.172.9/api/v2/monitor/virtual-wan/sla-log
Health check log	https://172.172.172.9/api/v2/monitor/virtual-wan/health-check

A comprehensive list of API calls with sample output is available on the [Fortinet Developer Network](#).

CLI diagnose commands:

```
# diagnose sys sdwan intf-sla-log port13
Timestamp: Wed Jan 9 18:33:49 2019, used inbandwidth: 3208bps, used outbandwidth:

```

Passive WAN health measurement

SD-WAN passive WAN health measurement determines the health check measurements using session information that is captured on firewall policies that have *Passive Health Check* (`passive-wan-health-measurement`) enabled. Passive measurements analyze session information that is gathered from various TCP sessions to determine the jitter, latency, and packet loss.

Using passive WAN health measurement reduces the amount of configuration required and decreases the traffic that is produced by health check monitor probes doing active measurements. Passive WAN health measurement analyzes real-life traffic; active WAN health measurement using a detection server might not reflect the real-life traffic.

By default, active WAN health measurement is enabled when a new health check is created. It can be changed to passive or prefer passive:

passive	Health is measured using traffic, without probes. No link health monitor needs to be configured.
prefer-passive	Health is measured using traffic when there is traffic, and using probes when there is no traffic. A link health monitor must be configured, see Link health monitor for details.

When `passive-wan-health-measurement` is enabled, `auto-asic-offload` will be disabled.

Example

In this example, the FortiGate is configured to load-balance between two WAN interfaces, port15 and port16. A health check is configured in passive mode, and SLA thresholds are set. Passive WAN health measurement is enabled on the SD-WAN policy.

Measurements are taken from YouTube traffic generated by the PC. When latency is introduced to the traffic on port15, the passive health check trigger threshold is exceeded and traffic is rerouted to port16.

To configure the SD-WAN in the GUI:

1. Create the SD-WAN zone:
 - a. Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab.
 - b. Click *Create New > SD-WAN Zone*.
 - c. Enter a name for the zone, such as *SD-WAN*.
 - d. Click *OK*.
2. Create the SD-WAN members:
 - a. Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab.
 - b. Click *Create New > SD-WAN Member*.
 - c. Set *Interface* to *port15*, *SD-WAN Zone* to *SD-WAN*, and *Gateway* set to *172.16.209.2*.
 - d. Click *OK*.
 - e. Click *Create New > SD-WAN Member* again.
 - f. Set *Interface* to *port16*, *SD-WAN Zone* to *SD-WAN*, and *Gateway* set to *172.16.210.2*.
 - g. Click *OK*.
3. Create a performance SLA:
 - a. Go to *Network > SD-WAN* and select the *Performance SLAs* tab.
 - b. Edit an existing health check, or create a new one.
 - c. Set *Probe mode* to *Passive*.
 - d. Set *Participants* to *Specify* and add *port15* and *port16*.
 - e. Configure two SLA targets. Note that the second SLA target must be configured in the CLI.

f. Configure the remaining settings as needed.

g. Click OK.

The SLA list shows the probe mode in the *Detect Server* column, if the probe mode is passive or prefer passive.

Probe packets can only be disabled in the CLI and when the probe mode is not passive.

4. Create SD-WAN rules:

- a. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
- b. Configure the first rule:

Name	Background_Traffic
Source address	172.16.205.0
Application	Click in the field, and in the <i>Select Entries</i> pane search for <i>YouTube</i> and select all of the entries
Strategy	Maximize Bandwidth (SLA)
Interface preference	port15 and port16
Required SLA target	Passive_Check#2

c. Click OK.

- d. Click *Create New* again and configure the second rule:

Name	Foreground_Traffic
Source address	172.16.205.0
Address	all
Protocol number	Specify - 1
Strategy	Lowest Cost (SLA)
Interface preference	port15 and port16
Required SLA target	Passive_Check#1

- e. Click *OK*.

To configure the firewall policy in the GUI:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the policy:

Name	SD-WAN-HC-policy
Incoming Interface	port5
Outgoing Interface	SD-WAN
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT
Passive Health Check	Enabled Passive health check can only be enabled in a policy when the outgoing interface is an SD-WAN zone.

3. Click *OK*.

To configure the SD-WAN in the CLI:

```
config system sdwan
  set status enable
  config zone
    edit "SD-WAN"
    next
  end
  config members
    edit 1
      set zone "SD-WAN"
      set interface "port15"
      set gateway 172.16.209.2
    next
```

```
edit 2
    set zone "SD-WAN"
    set interface "port16"
    set gateway 172.16.210.2
next
end
config health-check
    edit "Passive_Check"
        set detect-mode passive
        set members 1 2
        config sla
            edit 1
                set latency-threshold 500
                set jitter-threshold 500
                set packetloss-threshold 10
            next
            edit 2
                set latency-threshold 1000
                set jitter-threshold 1000
                set packetloss-threshold 10
            next
        end
    next
end
config service
    edit 1
        set name "Background_Traffic"
        set mode load-balance
        set src "172.16.205.0"
        set internet-service enable
        set internet-service-app-ctrl 31077 33321 41598 31076 33104 23397 30201 16420
17396 38569 25564
        config sla
            edit "Passive_Check"
                set id 2
            next
        end
        set priority-member 1 2
    next
    edit 2
        set name "Foreground_Traffic"
        set mode sla
        set src "172.16.205.0"
        set protocol 1
        set dst "all"
        config sla
            edit "Passive_Check"
                set id 1
            next
        end
        set priority-member 1 2
    next
end
end
```

To configure the firewall policy in the CLI:

```

config firewall policy
    edit 1
        set name "SD-WAN-HC-policy"
        set srcintf "port5"
        set dstintf "SD-WAN"
        set nat enable
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set passive-wan-health-measurement enable
        set auto-asic-offload disable
    next
end

```

Results**When both links pass the SLA:**

```

# diagnose sys link-monitor-passive interface
Interface port16 (28):
    Latency 10.000 Jitter 5.000 Packet_loss 0.000% Last_updated Fri Mar 5 10:09:21 2021

Interface port15 (27):
    Latency 60.000 Jitter 0.000 Packet_loss 0.000% Last_updated Fri Mar 5 10:39:24 2021

# diagnose sys sdwan health-check
Health Check(Passive_Check):
Seq(1 port15): state(alive), packet-loss(0.000%) latency(60.000), jitter(0.750) sla_map=0x3
Seq(2 port16): state(alive), packet-loss(0.000%) latency(10.000), jitter(5.000) sla_map=0x3

# diagnose sys sdwan service 2

Service(2): Address Mode(IPV4) flags=0x200
    Gen(1), TOS(0x0/0x0), Protocol(1: 1->65535), Mode(sla), sla-compare-order
    Members(2):

```

Passive health-check measurement by internet service and application

Passive health measurement supports passive detection for each internet service and application.

If internet services or applications are defined in an SD-WAN rule with passive health check, SLA information for each service or application will be differentiated and collected. SLA metrics (latency, jitter, and packet loss) on each SD-WAN member in the rule are then calculated based on the relevant internet service's or application's SLA information.

In this example, three SD-WAN rules are created:

- Rule 1: Best quality (latency) using passive SLA for the internet services Alibaba and Amazon.
- Rule 2: Best quality (latency) using passive SLA for the applications Netflix and YouTube.
- Rule 3: Best quality (latency) using passive SLA for all other traffic.

After passive application measurement is enabled for rules one and two, the SLA metric of rule one is the average latency of the internet services Alibaba and Amazon, and the SLA metric of rule two is the average latency of the applications Netflix and YouTube.

To configure the SD-WAN:

1. Configure the SD-WAN members:

```

config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
  end
  config members
    edit 1
      set interface "dmz"
      set gateway 172.16.208.2
    next
    edit 2
      set interface "port15"
      set gateway 172.16.209.2
    next
  end
end

```

2. Configure the passive mode health check:

```
config health-check
    edit "Passive_HC"
        set detect-mode passive
        set members 1 2
    next
end
```

3. Configure SD-WAN service rules:

```
config service
    edit 1
        set name "1"
        set mode priority
        set src "172.16.205.0"
        set internet-service enable
        set internet-service-name "Alibaba-Web" "Amazon-Web"
        set health-check "Passive_HC"
        set priority-members 1 2
        set passive-measurement enable //Enable "passive application measurement", it
is a new command which is introduced in this project.
    next
    edit 2
        set name "2"
        set mode priority
        set src "172.16.205.0"
        set internet-service enable
        set internet-service-app-ctrl 18155 31077
        set health-check "Passive_HC"
        set priority-members 1 2
        set passive-measurement enable ///Enable "passive application measurement"
    next
    edit 3
        set name "3"
        set mode priority
        set dst "all"
        set src "172.16.205.0"
        set health-check "Passive_HC"
        set priority-members 1 2
    next
end
```

4. Configure SD-WAN routes:

```
config router static
    edit 1
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
end
```

5. Configure the firewall policy with passive WAN health measurement enabled:

```
config firewall policy
    edit 1
        set uuid 972345c6-1595-51ec-66c5-d705d266f712
        set srcintf "port5"
        set dstintf "virtual-wan-link"
```

```

        set action accept
        set srcaddr "172.16.205.0"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set passive-wan-health-measurement enable
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "g-default"
        set auto-asic-offload disable
    next
end

```

To verify the results:

1. On the PC, open the browser and visit the internet services and applications.
2. On the FortiGate, check the collected SLA information to confirm that each server or application on the SD-WAN members was measured individually:

```

# diagnose sys link-monitor-passive interface

Interface dmz (5):
    Default(0x00000000): latency=3080.0  11:57:54, jitter=5.0      11:58:08,
    pktloss=0.0 % NA
    Alibaba-Web(0x00690001): latency=30.0  11:30:06, jitter=25.0   11:29:13,
    pktloss=0.0 % NA
    YouTube(0x00007965): latency=100.0  12:00:35, jitter=2.5    12:00:30,
    pktloss=0.0 % NA
    Netflix(0x000046eb): latency=10.0  11:31:24, jitter=10.0   11:30:30,
    pktloss=0.0 % NA
    Amazon-Web(0x00060001): latency=80.0  11:31:52, jitter=35.0   11:32:07,
    pktloss=0.0 % NA

Interface port15 (27):
    Default(0x00000000): latency=100.0  12:00:42, jitter=0.0    12:00:42,
    pktloss=0.0 % NA
    Amazon-Web(0x00060001): latency=30.0  11:56:05, jitter=0.0    11:55:21,
    pktloss=0.0 % NA
    Alibaba-Web(0x00690001): latency=0.0  11:26:08, jitter=35.0   11:27:08,
    pktloss=0.0 % NA
    YouTube(0x00007965): latency=100.0  11:33:34, jitter=0.0    11:33:50,
    pktloss=0.0 % NA
    Netflix(0x000046eb): latency=0.0  11:26:29, jitter=0.0    11:29:03,
    pktloss=0.0 % NA

```

3. Verify that the SLA metrics on the members are calculated as expected:

```

# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x600 use-shortcut-sla
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(priority), link-cost-factor

```

Mean opinion score calculation and logging in performance SLA health checks

The mean opinion score (MOS) is a method of measuring voice quality using a formula that takes latency, jitter, packet loss, and the codec into account to produce a score from zero to five (0 - 5). The G.711, G.729, and G.722 codecs can be selected in the health check configurations, and an MOS threshold can be entered to indicate the minimum MOS score for the SLA to pass. The maximum MOS score will depend on which codec is used, since each codec has a theoretical maximum limit.

```

config system sdwan
    config health-check
        edit <name>
            set mos-codec {g711 | g729 | g722}
            config sla
                edit <id>
                    set link-cost-factor {latency jitter packet-loss mos}
                    set mos-threshold <value>
                next
            end
        next
    end
end

```

<code>mos-codec {g711 g729 g722}</code>	Set the VoIP codec to use for the MOS calculation (default = g711).
<code>link-cost-factor {latency jitter packet-loss mos}</code>	Set the criteria to base the link selection on.
<code>mos-threshold <value></code>	Set the minimum MOS for the SLA to be marked as pass (1.0 - 5.0, default = 3.6).

To configure a health check to calculate the MOS:

```
config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
  end
  config members
    edit 1
      set interface "dmz"
      set gateway 172.16.208.2
    next
    edit 2
      set interface "port15"
      set gateway 172.16.209.2
    next
  end
  config health-check
    edit "Test_MOS"
      set server "2.2.2.2"
      set sla-fail-log-period 30
      set sla-pass-log-period 30
      set members 0
      set mos-codec g729
      config sla
        edit 1
          set link-cost-factor mos
          set mos-threshold "4.0"
        next
      end
    next
  end
end
```

To use an MOS SLA to steer traffic in an SD-WAN rule:

```
config system sdwan
  config service
    edit 1
      set name "MOS_traffic_steering"
      set mode sla
      set dst "HQ_LAN"
      set src "Branch_LAN"
      config sla
        edit "Test_MOS"
          set id 1
```

```

        next
    end
    set priority-members 0
next
end
end

```

The MOS currently cannot be used to steer traffic when the mode is set to priority.

To verify the MOS calculation results:

1. Verify the health check diagnostics:

```

# diagnose sys sdwan health-check
Health Check(Test_MOS):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.114), jitter(0.026), mos(4.123),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
Seq(2 port15): state(alive), packet-loss(0.000%) latency(0.100), jitter(0.008), mos
(4.123), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1

# diagnose sys sdwan sla-log Test_MOS 1
Timestamp: Tue Jan 4 11:23:06 2022, vdom root, health-check Test_MOS, interface: dmz,
status: up, latency: 0.151, jitter: 0.040, packet loss: 0.000%, mos: 4.123.
Timestamp: Tue Jan 4 11:23:07 2022, vdom root, health-check Test_MOS, interface: dmz,
status: up, latency: 0.149, jitter: 0.041, packet loss: 0.000%, mos: 4.123.

# diagnose sys sdwan sla-log Test_MOS 2
Timestamp: Tue Jan 4 11:25:09 2022, vdom root, health-check Test_MOS, interface:
port15, status: up, latency: 0.097, jitter: 0.009, packet loss: 0.000%, mos: 4.123.
Timestamp: Tue Jan 4 11:25:10 2022, vdom root, health-check Test_MOS, interface:
port15, status: up, latency: 0.097, jitter: 0.008, packet loss: 0.000%, mos: 4.123.

```

2. Change the mos-codec to g722. The diagnostics will now display different MOS values:

```

# diagnose sys sdwan health-check
Health Check(Test_MOS):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.150), jitter(0.031), mos(4.453),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
Seq(2 port15): state(alive), packet-loss(0.000%) latency(0.104), jitter(0.008), mos
(4.453), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1

```

3. Increase the latency on the link in port15. The calculated MOS value will decrease accordingly. In this example, port15 is out of SLA since its MOS value is now less than the 4.0 minimum:

```

# diagnose sys sdwan health-check
Health Check(Test_MOS):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.106), jitter(0.022), mos(4.453),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
Seq(2 port15): state(alive), packet-loss(0.000%) latency(300.119), jitter(0.012), mos
(3.905), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x0

```

Embedded SD-WAN SLA information in ICMP probes

In the hub and spoke SD-WAN design, in order for traffic to pass symmetrically from spoke to hub and hub to spoke, it is essential for the hub to know which IPsec overlay is in SLA and out of SLA. Prior to introducing embedded SLA information in ICMP probes, it is common practice for spokes to use the SD-WAN neighbor feature and `route-map-out-preferable` setting to signal the health of each overlay to the hub. However, this requires BGP to be configured per overlay, and to manipulate BGP routes using custom BGP communities.

With embedded SLA information in ICMP probes, spokes can communicate their SLA for each overlay directly through ICMP probes to the hub. The hub learns these SLAs and maps the status for each spoke and its corresponding overlays.

The hub uses the SLA status to apply priorities to the IKE routes, giving routes over IPsec overlays that are within SLAs a lower priority value and routes over overlays out of SLAs a higher priority value. If BGP is used, recursively resolved BGP routes can inherit the priority from its parent.

Embedded SLA information in ICMP probes allows hub and spoke SD-WAN to be designed with a BGP on loopback topology, or without BGP at all. The following topology outlines an example of the BGP on loopback design where each spoke is peered with the hub and route reflector on the loopback interface.

In this topology, each FortiGate's BGP router ID is based on its Loopback0 interface. Each spoke has SLA health checks defined to send ICMP probes to the server's Lo_HC interface on 172.31.100.100. The ICMP probes include embedded SLA information for each SD-WAN overlay member.

Related SD-WAN settings:

```
config system sdwan
  config health-check
    edit <name>
      set detect-mode {active | passive | prefer-passive | remote}
      set embed-measured-health {enable | disable}
      config sla
        edit <id>
          set priority-in-sla <integer>
          set priority-out-sla <integer>
        next
      end
      set sla-id-redistribute <id>
    next
  end
end
```

```
detect-mode {active |
  passive | prefer-
  passive | remote}
```

Set the mode that determines how to detect the server:

- **active:** the probes are sent actively (default).
- **passive:** the traffic measures health without probes.
- **prefer-passive:** the probes are sent in case of no new traffic.
- **remote:** the link health is obtained from remote peers.

<code>embed-measured-health {enable disable}</code>	Enable/disable embedding SLA information in ICMP probes (default = disable).
<code>set priority-in-sla <integer></code>	Set the priority that will be set to the IKE route when the corresponding overlay is in SLA (0 - 65535).
<code>set priority-out-sla <integer></code>	Set the priority that will be set to the IKE route when the corresponding overlay is out of SLA (0 - 65535).
<code>sla-id-redistribute <id></code>	Set the SLA entry (ID) that will be applied to the IKE routes (0 - 32, default = 0).

Related BGP setting:

```
config router bgp
    set recursive-inherit-priority {enable | disable}
end
```

<code>recursive-inherit-priority {enable disable}</code>	Enable/disable allowing recursive resolved BGP routes to inherit priority from its parent (default = disable).
--	--

Example with BGP on loopback SD-WAN

This example demonstrates the configurations needed to configure the SD-WAN and BGP settings for the preceding topology. It is assumed that IPsec VPN overlays are already configured per the topology, and that loopback interfaces are already configured on each FortiGate.

Configuring the Spoke_1 FortiGate

In the SD-WAN settings, note the following requirements:

1. Configure the SD-WAN zones and members. For each SD-WAN member, define the source of its probes to be the Loopback0 interface IP.
2. Configure the SLA health check to point to the Hub's Lo_HC interface and IP. Enable `embed-measured-health`.
3. Configure an SD-WAN service rule to route traffic based on the maximize bandwidth (SLA) algorithm to prefer member H1_T11 over H1_T22.
4. Configure `set exchange-interface-ip enable` and `set exchange-ip-addr4` to the Loopback0 interface IP. The `exchange-interface-ip` option is automatically turned on when ADVPN has already been configured. If ADVPN has not been configured, then `set exchange-interface-ip enable` must be configured before `set exchange-ip-addr4` can be configured.

To configure the SD-WAN settings:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "overlay"
        next
    end
    config members
        edit 1
```

```

        set interface "H1_T11"
        set zone "overlay"
        set source 172.31.0.65
    next
    edit 4
        set interface "H1_T22"
        set zone "overlay"
        set source 172.31.0.65
    next
end
config health-check
    edit "HUB"
        set server "172.31.100.100"
        set embed-measured-health enable
        set members 0
        config sla
            edit 1
                set link-cost-factor latency
                set latency-threshold 100
            next
        end
    next
end
config service
    edit 1
        set mode sla
        set dst "CORP_LAN"
        set src "CORP_LAN"
        config sla
            edit "HUB"
                set id 1
            next
        end
        set priority-members 1 4
    next
end
end

```

To configure the BGP settings:

```

config router bgp
    set as 65001
    set router-id 172.31.0.65
    config neighbor
        edit "172.31.0.1"
            set remote-as 65001
            set update-source "Loopback0"
        next
    end
    config network
        edit 1
            set prefix 10.0.3.0 255.255.255.0
        next
    end
end

```

To add the loopback IP to the IPsec interface settings:

```

config vpn ipsec phase1-interface
    edit "H1_T11"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.65
    next
    edit "H1_T22"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.65
    next
end

```

Configuring the hub FortiGate

In the SD-WAN settings, note the following requirements:

1. Configure the SD-WAN zone and members.
2. Configure the SLA health checks to detect SLAs based on the remote site (spoke). This must be defined for each SD-WAN member:
 - a. For the SLA, specify the same link cost factor and metric as the spoke (100).
 - b. Define the IKE route priority for in and out of SLA. Lower priority values have higher priority than higher priority values.
3. Define the SLA entry ID that will be applied to the IKE routes.
4. Configure `set exchange-interface-ip enable` and `set exchange-ip-addr4` to the Loopback0 interface IP. The `exchange-interface-ip` option is automatically turned on when ADVPN has already been configured. If ADVPN has not been configured, then `set exchange-interface-ip enable` must be configured before `set exchange-ip-addr4` can be configured.

To configure the SD-WAN settings:

```

config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "EDGE_T1"
        next
        edit 2
            set interface "EDGE_T2"
        next
    end
    config health-check
        edit "1"
            set detect-mode remote
            set sla-id-redistribute 1
            set members 1
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
            next
        next
    end
end

```

```

        set priority-in-sla 10
        set priority-out-sla 20
    next
end
next
edit "2"
    set detect-mode remote
    set sla-id-redistribute 1
    set members 2
    config sla
        edit 1
            set link-cost-factor latency
            set latency-threshold 100
            set priority-in-sla 15
            set priority-out-sla 25
        next
    end
next
end
end

```

In the BGP settings, note the following requirements:

1. Enable `recursive-inherit-priority` to inherit the route priority from its parent, which is the priority defined in the health check SLA settings.
2. Configure the other BGP settings similar to a regular BGP hub.

To configure the BGP settings:

```

config router bgp
    set as 65001
    set router-id 172.31.0.1
    set recursive-inherit-priority enable
    config neighbor-group
        edit "EDGE"
            set remote-as 65001
            set update-source "Loopback0"
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 172.31.0.64 255.255.255.192
            set neighbor-group "EDGE"
        next
    end
end

```

To add the loopback IP to the IPsec interface settings:

```

config vpn ipsec phase1-interface
    edit "EDGE_T1"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.1
    next
    edit "EDGE_T2"

```

```

        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.1
    next
end

```

Testing and verification

Once the hub and spokes are configured, verify that SLA statuses are passed from the spoke to the hub.

To verify that the SLA statuses are passed from the spoke to the hub:

1. On Spoke_1, display the status of the health-checks for H1_T11 and H1_T22:

```

# diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(0.228), jitter(0.018), mos
(4.404), bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x1
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.205), jitter(0.007), mos
(4.404), bandwidth-up(999998), bandwidth-dw(1000000), bandwidth-bi(1999998) sla_map=0x1

```

2. On Spoke_1, display the status and order of the overlays in the SD-WAN service rule:

```

# diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Tie break: cfg
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Members(2):
    1: Seq_num(1 H1_T11), alive, sla(0x1), gid(0), cfg_order(0), local cost(0), selected
    2: Seq_num(4 H1_T22), alive, sla(0x1), gid(0), cfg_order(3), local cost(0), selected

Src address(1):
    10.0.0.0-10.255.255.255
Dst address(1):
    10.0.0.0-10.255.255.255

```

Both overlays are within SLA, so H1_T11 is preferred due to its `cfg-order`.

Spoke_1's SLA information for H1_T11 and H1_T22 is embedded into the ICMP probes destined for the hub's Lo_HC interface. The hub receives this information and maps the SLAs correspondingly per spoke and overlay based on the same SLA targets.

As a result, since all SLAs are within target, the hub sets the routes over each overlay as follows:

Hub SD-WAN member	Overlay	SLA status	Priority for IKE routes
1	EDGE_T1	0x1 – within SLA	10
2	EDGE_T2	0x1 – within SLA	15

3. Verify that the spoke has sent its health check result to hub.

- a. On the hub, display the status of the health checks for EDGE_T1 and EDGE_T2:

```

# diagnose sys sdwan health-check remote
Remote Health Check: 2(2)
    Passive remote statistics of EDGE_T2(22):
EDGE_T2_0(172.31.3.5): timestamp=02-09 16:19:11, latency=1.056, jitter=0.582,
pktloss=0.000%

```

```
Remote Health Check: 1(1)
  Passive remote statistics of EDGE_T1(21):
EDGE_T1_0(172.31.3.1): timestamp=02-09 16:19:11, latency=1.269, jitter=0.675,
pktloss=0.000%
```

4. When there are multiple spokes, additional options can be used to filter a spoke by health check name, or health check name and the member's sequence number (diagnose system sdwan health-check remote <hc_name> <seq_num>).

- a. To filter the health check by health check name:

```
# diagnose sys sdwan health-check remote 1
Remote Health Check: 1(1)
  Passive remote statistics of EDGE_T1(21):
EDGE_T1_0(172.31.3.1): timestamp=02-09 16:43:37, latency=1.114, jitter=0.473,
pktloss=0.000%
```

When this method is used, the output displays all the members of the specified health check name.

- b. To filter the health check by health check name and the member's sequence number:

```
# diagnose sys sdwan health-check remote 1 1
Remote Health Check: 1(1)
  Passive remote statistics of EDGE_T1(21):
EDGE_T1_0(172.31.3.1): timestamp=02-09 16:43:41, latency=1.178, jitter=0.497,
pktloss=0.000%
```

When this method is used, the output displays the specified member of the specified health check name.

If the detect-mode is set to remote, use `diagnose sys sdwan health-check remote` in lieu of `diagnose sys sdwan health-check`.

5. Simultaneously, BGP recursive routes inherit the priority based on the parent IKE routes. The recursively resolved BGP routes that pass through EDGE_T1 will have a priority of 10, and routes that pass through EDGE_T2 will have a priority of 15. Therefore, traffic from the hub to the spoke will be routed to EDGE_T1.

Verify the routing tables.

- a. Static:

```
# get router info routing-table static
Routing table for VRF=0
S      172.31.0.65/32 [15/0] via EDGE_T1 tunnel 10.0.0.69 vrf 0, [10/0]
                                         [15/0] via EDGE_T2 tunnel 172.31.0.65 vrf 0, [15/0]
```

- b. BGP:

```
# get router info routing-table bgp
Routing table for VRF=0
B      10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T1 tunnel 10.0.0.69
vrf 0 [10]), 04:32:53
                                         (recursive via EDGE_T2 tunnel 172.31.0.65
vrf 0 [15]), 04:32:53, [1/0]
```

Next, test by making the health checks over the spokes' H1_T11 tunnel out of SLA. This should trigger traffic to start flowing from the spokes' H1_T22 tunnel. Consequently, the SLA statuses are passed from the spoke to the hub, and the hub will start routing traffic to EDGE_T2.

To verify that the hub will start routing traffic to EDGE_T2 when the spoke H1_T11 tunnel is out of SLA:

1. On Spoke_1, display the status of the health checks for H1_T11 and H1_T22:

```
# diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(120.228), jitter(0.013), mos
(4.338), bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x0
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.220), jitter(0.008), mos
(4.404), bandwidth-up(999998), bandwidth-dw(1000000), bandwidth-bi(1999998) sla_map=0x1
```

2. Verify the routing tables.

- a. Static:

```
# get router info routing-table static
Routing table for VRF=0
S      172.31.0.65/32 [15/0] via EDGE_T2 tunnel 172.31.0.65 vrf 0, [15/0]
                               [15/0] via EDGE_T1 tunnel 10.0.0.69 vrf 0, [20/0]
```

The priority for EDGE_T1 has changed from 10 to 20.

- b. BGP:

```
# get router info routing-table bgp
Routing table for VRF=0
B      10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T2 tunnel 172.31.0.65
vrf 0 [15]), 00:01:19
                               (recursive via EDGE_T1 tunnel 10.0.0.69
vrf 0 [20]), 00:01:19, [1/0]
```

EDGE_T2 is now preferred. The priority for EDGE_T1 has changed from 10 to 20.

Spoke_1's SLA information for H1_T11 embedded into the ICMP probes has now changed.

As a result, the hub sets the routes over each overlay as follows:

Hub SD-WAN member	Overlay	SLA status	Priority for IKE routes
1	EDGE_T1	0x0 – out of SLA	20
2	EDGE_T2	0x1 – within SLA	15

The BGP recursive routes inherit the priority based on the parent IKE routes. Since priority for IKE routes on EDGE_T1 has changed to 20, recursively resolved BGP routes passing through EDGE_T1 has also dropped to 20. As a result, hub to spoke_1 traffic will go over EDGE_T2.

SD-WAN application monitor using FortiMonitor

The agent-based health check detection mode works with FortiMonitor to provide more accurate user level performance statistics. FortiMonitor acts as an agent and sends health check probes on behalf of the monitored FortiGate interface. FortiMonitor mimics a real user, and the probes return a more accurate application level performance. The SLA information collected from FortiMonitor is sent back to the FortiGate as the monitored interface's SLA information. These statistics can be used to gain a deeper insight into the SD-WAN traffic performance.

FortiGate can log statistics when using FortiMonitor to detect advanced SD-WAN application performance metrics. These logs may also be sent to FortiAnalyzer and FortiManager for review and reporting.

```

config system sdwan
    config health-check
        edit <name>
            set detect-mode agent-based
        next
    end
    config service
        edit <id>
            set agent-exclusive {enable | disable}
        next
    end
    set app-perf-log-period <time in seconds>
end

```

The following diagnostic commands can be used to view agent related metrics:

```
# diagnose sys link-monitor-passive agent <option>
```

list	List all the collected reports.
list-app	List the details of each application.
flush	Flush all the collected reports.
flush-app	Flush the details of all the applications.
agent-oif-map	List the agent and interface maps.

Example

In this example, routing is achieved through SD-WAN rules. The agent-based health check detection mode creates the FortiMonitor IP address and FortiGate SD-WAN interface map.

This example assumes that the FortiMonitor has already been added to the Security Fabric (see [Configuring FortiMonitor on page 2827](#) for detailed instructions). The FortiMonitor OnSight (client) can be configured for two or more IP addresses, and each IP address is capable of sending application probes to user-specified applications.

Specific routing is implemented on the FortiGate to ensure each FortiMonitor client collects performance statistics for only one SD-WAN member interface. The FortiMonitor is configured to send application-specific probes to measure that application's performance on a given SD-WAN member. The FortiGate uses the FortiMonitor performance statistics to determine link quality based on application performance by mapping the health check. The link quality for a given application can then be used to steer the matching application traffic with greater accuracy.

To configure the FortiGate:**1. Configure the address objects for each FortiMonitor client:**

```
config firewall address
  edit "FMR_OnSight1"
    set subnet 10.2.1.80 255.255.255.255
  next
  edit "MR_OnSight2"
    set subnet 10.2.1.81 255.255.255.255
  next
end
```

2. Set the logging frequency:

```
config system sdwan
  set status enable
  set app-perf-log-period 60
end
```

3. Configure the SD-WAN zone and members:

```
config system sdwan
  config zone
    edit "virtual-wan-link"
    next
  end
  config members
    edit 1
      set interface "v1236"
      set gateway 10.12.36.2
    next
    edit 2
      set interface "v1237"
      set gateway 10.12.37.20
    next
  end
end
```

4. Configure the SD-WAN rules to ensure each OnSight client uses only one SD-WAN member, and map the FortiMonitor IP to an SD-WAN member (interface):

```
config system sdwan
  config service
    edit 1
      set dst "all"
      set src "FMR_OnSight1"
      set priority-members 1
      set agent-exclusive enable
    next
    edit 2
      set dst "all"
      set src "FMR_OnSight2"
      set priority-members 2
      set agent-exclusive enable
    next
  end
end
```

5. Configure the SD-WAN health check:

```

config health-check
    edit "FMR"
        set detect-mode agent-based
        set members 1 2
        config sla
            edit 1
                next
            end
        next
    end
end

```

To verify the SD-WAN member performance:**1. Verify the health check diagnostics:**

```

# diagnose sys sdwan health-check
Health Check(FMR):
Seq(1 v1236): state(alive), packet-loss(0.000%) latency(183.214), jitter(0.124), mos
(4.225), bandwidth-up(999992), bandwidth-dw(999976), bandwidth-bi(1999968) sla_map=0x0
Seq(2 v1237): state(alive), packet-loss(0.000%) latency(182.946), jitter(0.100), mos
(4.226), bandwidth-up(999998), bandwidth-dw(999993), bandwidth-bi(1999991) sla_map=0x0

```

2. Verify the collected reports:

```

# diagnose sys link-monitor-passive agent list
v1236( 23) | src=10.2.1.80 | latency=183.2    20:27:24 | jitter=0.1    20:27:24 |
pktloss=0.0 % 20:27:24
v1237( 24) | src=10.2.1.81 | latency=182.9    20:27:24 | jitter=0.1    20:27:24 |
pktloss=0.0 % 20:27:24

```

3. Verify the details of each application:

```

# diagnose sys link-monitor-passive agent list-app
app_id=0x00000000, app=fortinet.com, dev=v1236(23)
    latency=183.2, jitter=0.1, pktloss=0.0, ntt=99.2, srt=384.8, app_err=0.0, 20:28:25
app_id=0x00000000, app=fortinet.com, dev=v1237(24)
    latency=183.1, jitter=0.5, pktloss=0.0, ntt=104.4, srt=377.8, app_err=0.0, 20:28:25

```

4. Verify the agent and interface maps:

```

# diagnose sys link-monitor-passive agent agent-oif-map
oif=v1236(23), src=10.2.1.80
oif=v1237(24), src=10.2.1.81

```

5. Review the SD-WAN logs:**6. # execute log filter category event**
execute log filter field subtype sdwan
execute log display

```

1: date=2023-01-27 time=16:32:15 eventtime=1674865935918381398 tz="-0800"

Classifying SLA probes for traffic prioritization

Traffic classification on SLA probes helps to ensure that they are prioritized in times of congestion. This prevents SD-WAN link flapping and unexpected routing behaviors, and stabilizes SD-WAN from unnecessary failovers.

SLA probes can be classified into a specific class ID so that SLA probes assigned to a class ID with higher priority are prioritized over other traffic. SLA probes are assigned using the `class-id` command:

```

config system sdwan
  config health-check
    edit <health-check name>
      set class-id <class name>
    next

```

```
end
end
```

For more information on traffic shaping, see [Traffic shaping on page 1341](#).

Example

In this example, SLA probes are assigned into different class ID. The interfaces dmz and vd1-01 both have outbandwidth of 1000000 Kbps (1 Gbps) configured. Three traffic shaping classes are defined:

Class ID	Name	Definition
2	sla_probe	High priority with a guaranteed 10% of bandwidth (100 Mbps)
3	default	Low priority with a guaranteed 80% of bandwidth (800 Mbps)
4	sla_probe_2	Medium priority with a guaranteed 10% of bandwidth (100 Mbps)

Under this scheme, when congestion occurs, traffic in each class will have their guaranteed bandwidth honored. If there is remaining bandwidth, higher priority traffic will get the bandwidth. On the SD-WAN health check, probes to server 2.2.2.2 are assigned to class 2 (sla_probe). This means it has a guaranteed bandwidth and has the highest priority to use unused bandwidth. This allows SD-WAN health check to function properly even during times of congestion.

To classify SLA probes for traffic prioritization:

1. Configure the firewall traffic class:

```
config firewall traffic-class
    edit 2
        set class-name "sla_probe"
    next
    edit 3
        set class-name "default"
    next
    edit 4
        set class-name "sla_probe_2"
    next
end
```

2. Configure the class ID priority and guaranteed bandwidth:

```
config firewall shaping-profile
    edit "profile-1"
        set default-class-id 3
        config shaping-entries
            edit 2
                set class-id 2
                set priority high
            next
        next
    next
end
```

```

        set guaranteed-bandwidth-percentage 10
        set maximum-bandwidth-percentage 100
    next
    edit 3
        set class-id 3
        set priority low
        set guaranteed-bandwidth-percentage 80
        set maximum-bandwidth-percentage 100
    next
    edit 4
        set class-id 4
        set priority medium
        set guaranteed-bandwidth-percentage 10
        set maximum-bandwidth-percentage 100
    next
end
next
end

```

3. Configure the interfaces:

```

config system interface
    edit "dmz"
        set outbandwidth 1000000
        set egress-shaping-profile "profile-1"
        ...
    next
    edit "vd1-p1"
        set outbandwidth 1000000
        set egress-shaping-profile "profile-1"
        ...
    next
end

```

4. Configure the SD-WAN health check and assign the SLA probes into class 2:

```

config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 2
            set interface "vd1-p1"
        next
    end
    config health-check
        edit "1"
            set server "2.2.2.2"
            set members 1 2
            set class-id 2
            config sla

```

```

edit 1
next
end
next
end
end
end

```

To verify the SLA probe assignment:

1. Verify the health check diagnostics:

```

# diagnose sys sdwan health-check
Health Check(1):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.247), jitter(0.022), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
Seq(2 vd1-p1): state(alive), packet-loss(0.000%) latency(0.247), jitter(0.018), mos
(4.404), bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x1

```

2. Verify the SLA probes are assigned into class 2:

```

# diagnose netlink interface list dmz
if=dmz family=00 type=1 index=5 mtu=1500 link=0 master=0
ref=36 state=start present fw_flags=10018000 flags=up broadcast run multicast

                dropped_packets=0    dropped_bytes=0
stat: rxp=4097 txp=4586 rxb=540622 txb=221500 rx=0 txe=19 rxd=0 txd=0 mc=0
collision=0 @ time=1675121742
re: rxl=0 rxo=0 rxc=0 rxf=0 rxfi=0 rxm=0
te: txa=0 txc=0 txfi=0 txh=0 txw=0
misc rxc=0 txc=0
input_type=0 state=3 arp_entry=0 refcnt=20

```

When verifying the class assignment, the counter value should increase.

The example also demonstrates assigning SLA probes to class 4 (sla_probe_2), in which case the probes get medium priority.

To assign the SLA probe to medium priority:

1. Assign SLA probes into class 4:

```

config sys sdwan
    config health-check
        edit 1
            set class-id 4
        next
    end
    set status disable
end
config sys sdwan
    set status enable
end

```

2. Verify the SLA probes are assigned into class 4.

```

# diagnose netlink interface list dmz
if=dmz family=00 type=1 index=5 mtu=1500 link=0 master=0
ref=34 state=start present fw_flags=10018000 flags=up broadcast run multicast
Qdisc=mq hw_addr=e0:23:ff:9d:f9:9e broadcast_addr=ff:ff:ff:ff:ff:ff
egress traffic control:
    bandwidth=1000000 (kbps) lock_hit=0 default_class=3 n_active_class=3
    class-id=3    allocated-bandwidth=800000 (kbps)    guaranteed-
bandwidth=800000 (kbps)
                max-bandwidth=1000000 (kbps)    current-bandwidth=1 (kbps)
                priority=low    forwarded_bytes=24K

SD-WAN rules

SD-WAN rules, which are sometimes called *service rules*, identify traffic of interest, and then route the traffic based on a strategy and the condition of the route or *link* between two devices. You can use many strategies to select the outgoing interface and many performance service level agreements (SLAs) to evaluate the link conditions.

Use the following topics to learn about and create SD-WAN rules for your needs:

- [SD-WAN rules overview on page 767](#)
- [Implicit rule on page 775](#)
- [Automatic strategy on page 779](#)
- [Manual strategy on page 780](#)
- [Best quality strategy on page 783](#)
- [Lowest cost \(SLA\) strategy on page 787](#)
- [Load balancing strategy NEW on page 793](#)

SD-WAN rules overview

SD-WAN rules control how sessions are distributed to SD-WAN members. You can configure SD-WAN rules from the GUI and CLI.

From the GUI, go to *Network > SD-WAN > SD-WAN Rules*. When creating a new SD-WAN rule, or editing an existing SD-WAN rule, use the *Source* and *Destination* sections to identify traffic, and use the *Outgoing interfaces* section to configure WAN intelligence for routing traffic.

Priority Rule

Name:

From the CLI, use the following command to configure SD-WAN rules:

```
config system sdwan
  config service
    edit <ID>
      next
    end
  end
end
```

The following topics describe the fields used to configure SD-WAN rules:

- [Fields for identifying traffic on page 768](#)
- [Fields for configuring WAN intelligence on page 771](#)
- [Additional fields for configuring WAN intelligence on page 774](#)

Fields for identifying traffic

This topic describes the fields in an SD-WAN rule used for defining the traffic to which the rule applies. Some fields are available only in the CLI.

SD-WAN rules can identify traffic by a variety of means:

Address type	Source	Destination
IPv4/6	✓	✓
MAC	✓	✓
Group	✓	✓
FABRIC_DEVICE dynamic address	✓	✓
Users	✓	✓
User groups	✓	✓
Application control (application aware routing)		✓
Internet service database (ISDB)		✓
BGP route tags		✓
Differentiated Services Code Point (DSCP) tags		✓

In the GUI, go to *Network > SD-WAN > SD-WAN Rules*. Click *Create New*, or double-click an existing rule to open it for editing. The *Source* and *Destination* sections are used to identify traffic for the rule:

Priority Rule

In the CLI, edit the service definition ID number to identify traffic for the rule:

```
config system sdwan
  config service
    edit <ID>
      <CLI commands from the following tables>
      ...
    end
  end
end
```

The following table describes the fields used for the name, ID, and IP version of the SD-WAN rule:

ID, Name, and IP version		
Field	CLI	Description
ID	<pre>config system sdwan config service edit <ID> next end end</pre>	ID is generated when the rule is created. You can only specify the ID from the CLI.
Name	<pre>set name <string></pre>	The name does not need to relate to the traffic being matched, but it is good practice to have intuitive rule names.
IP version	<pre>set addr-mode <ipv4 ipv6></pre>	<p>The addressing mode can be IPv4 or IPv6.</p> <p>To configure in the GUI, IPv6 must be enabled from <i>System > Feature Visibility</i> page.</p>

The following table describes the fields used for source section of the SD-WAN rule:

Source		
Field	CLI	Description
Source address	<pre>set src <object></pre>	One or more address objects.

Source		
Field	CLI	Description
	Can be negated from the CLI with <code>set src-negate</code> .	
User group	<code>set users <user object></code> <code>set groups <group object></code>	Individual users or user groups
Source interface (input-device)	<code>set input-device <interface name></code> Can be negated with <code>set input-device-negate enable</code> .	CLI only. Select one or more source interfaces.

The following table describes the fields used for the destination section of the SD-WAN rule:

Destination		
Field	CLI	Description
Address	<code>set dst <object></code> <code>set protocol <integer></code> <code>set start-port <integer></code> <code>set end-port <integer></code> Use <code>set dst-negate enable</code> to negate the address object.	One or more address objects. One protocol and one port range can be combined with the address object. If it is necessary for an SD-WAN rule to match multiple protocols or multiple port ranges, you can create a custom Internet Service.
Internet Service	<code>set internet-service enable</code> <code>set internet-service-custom <name_1> <name_2> ... <name_n></code> <code>set internet-service-custom-group <name_1> <name_2> ... <name_n></code> <code>set internet-service-name <name_1> <name_2> ... <name_n></code> <code>set internet-service-group <name_1> <name_2> ... <name_n></code>	One or more internet services or service groups.
Application	<code>set internet-service-app-ctrl <id_1> <id_2> ... <id_n></code> <code>set internet-service-app-ctrl-group <name_1> <name_2> ... <name_n></code> <code>set internet-service-app-ctrl-category <id_1> <id_2> ... <id_n></code>	One or more applications or application groups. Can be used with internet services or service group.
Route tag (route-tag)	<code>set route-tag <integer></code>	CLI only.

Destination		
Field	CLI	Description
		This replaces the <code>dst</code> field (if previously configured) and matches a BGP route tag configured in a route map. See Using BGP tags with SD-WAN rules on page 864 .
TOS mask (<code>tos-mask</code>)	<code>set tos-mask <8-bit hex value></code>	CLI only. In order to leverage type of service (TOS) matching or DSCP matching on the IP header, the SD-WAN rule must specify the bit mask of the byte holding the TOS value. For example, a TOS mask of 0xe0 (11100000) matches the upper 3 bits.
TOS (<code>tos</code>)	<code>set tos <8 bit hex value></code>	CLI only. The value specified here is matched after the <code>tos-mask</code> is applied. For example, the FortiGate receives DSCP values 110000 and 111011. (DSCP is the upper 6 bits of the TOS field – 11000000 and 11101100 respectively). Using the TOS value 0xe0 (11100000), only the second DSCP value is matched.

By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System > Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
    set gui-app-detection-sdwan enable
end
```

Fields for configuring WAN intelligence

This topic describes the fields in an SD-WAN rule used for configuring WAN intelligence, which processes and routes traffic that matches the SD-WAN rule.

In the GUI, go to *Network > SD-WAN > SD-WAN Rules*. Click *Create New*, or double-click an existing rule to open it for editing. The *Outgoing Interfaces* section is used to configure WAN intelligence for the rule:

Priority Rule

SettingsInfo

WAN intelligence is comprised of the following parts:

- [Interface or zone preference on page 772](#)
- [Strategy on page 773](#)
- [Performance SLA on page 773](#)

Interface or zone preference

By default, the configured order of interfaces and/or zones in a rule are used. Interfaces and zones that are selected first have precedence over interfaces selected second and so on.

You can specify both interfaces and zones. When a zone is specified in the *Zone preference* field, it is equivalent to selecting each of the contained interface members in the *Interface preference* section. Interface members in a zone have lower priority than interfaces configured in the *Interface preference* section.

For example:

- There are 3 interfaces: port1, port2 and port3.
 - Port2 is in Zone1
 - Port1 and port3 belong to the default *virtual-wan-link* zone.
- An SD-WAN rule is created with *Interface preference* set to *port3* and *port1*, and *Zone preference* set to *Zone1*.

Interface preference	 port3  port1 <div style="text-align: center;">+</div>	<div style="text-align: right;">✕</div> <div style="text-align: right;">✕</div>
Zone preference	 Zone1 <div style="text-align: center;">+</div>	<div style="text-align: right;">✕</div>

The SD-WAN rule prefers the interfaces in the following order:

1. port3
2. port1
3. port2

You can configure the interface and zone preference in the CLI:

```
config system sdwan
  config service
    edit <ID>
      set priority-members <integer>
      set priority-zone <interface>
    next
  end
end
```

Strategy

Strategy dictates how the interface and/or zone order changes as link conditions change. You can use the following strategies:

- Automatic (`auto`): interfaces are assigned a priority based on quality. See [Automatic strategy on page 779](#).
- Manual (`manual`): interfaces are manually assigned a priority. See [Manual strategy on page 780](#).
- Best Quality (`priority`): interfaces are assigned a priority based on the `link-cost-factor` of the interface. See [Best quality strategy on page 783](#).
- Lowest cost (SLA) (`sla`): interfaces are assigned a priority based on selected SLA settings. See [Lowest cost \(SLA\) strategy on page 787](#).

Performance SLA

The best quality, lowest cost, and maximize bandwidth strategies are the most intelligent modes, and they leverage SLA health checks to provide meaningful metrics for a given link. FortiGate uses the metrics to make intelligent decisions to route traffic.

Automatic and manual strategies have pre-configured logic that do not leverage SLA health checks.

The goal of the performance SLA is to measure the quality of each SD-WAN member link. The following methods can be used to measure the quality of a link:

- Active measurement
 - Health-check traffic is sent to a server with a variety of protocols options.
 - The following SLA metrics are measured on this probe traffic:
 - Latency
 - Jitter
 - Packet loss
- Passive measurement
 - SLA metrics are measured on real or live traffic, reducing the amount of probe traffic that is sent and received.
 - There is the option (`prefer passive`) to initiate probe traffic when no live traffic is present.

Performance SLA is utilized by `auto`, *Lowest Cost (SLA)*, *Maximize Bandwidth (SLA)*, and *Best Quality* strategies. *Lowest Cost (SLA)* and *Maximize Bandwidth SLA* use SLA targets in a pass or fail style to evaluate whether a link is considered for traffic. *Best Quality* compares a specific metric of the SLA to pick the best result.

Therefore it is integral to select or create an SLA target(s) that relates to the traffic targeted by the rule. It does not make sense to evaluate a public resource, such as YouTube, when the rule matches Azure traffic.

See [Performance SLA on page 725](#) for more details.

Additional fields for configuring WAN intelligence

This topic describes the fields in an SD-WAN rule used for configuring WAN intelligence for egress traffic:

- [Forward and/or reverse differentiated services code point \(DSCP\) on page 774](#)
- [Default and gateway options on page 774](#)

For information about accessing fields for configuring WAN intelligence, see [Fields for configuring WAN intelligence on page 771](#).

Forward and/or reverse differentiated services code point (DSCP)

The FortiGate differentiated services feature can be used to change the DSCP value for all packets accepted by a policy.

The packet's `DSCP` field for traffic initiating a session (forward) or for reply traffic (reverse) can be changed and enabled in each direction separately by configuring it in the firewall policy using the *Forward DSCP* and *Reverse DSCP* fields.

From the CLI:

```
config system sdwan
  config service
    edit <ID>
      ...
      set dscp-forward enable
      ...
    next
  end
end
```

<code>set dscp-forward enable</code>	Enable use of forward DSCP tag.
<code>set dscp-forward-tag 000000</code>	Forward traffic DSCP tag.
<code>set dscp-reverse enable</code>	Enable use of reverse DSCP tag.
<code>set dscp-reverse-tag 000000</code>	Reverse traffic DSCP tag.

Default and gateway options

Following are additional gateway options that can be set only in the CLI:

```
config system sdwan
  config service
    edit <ID>
      ...
      set default enable
      ...
    next
  end
end
```

<code>set default [enable disable]</code>	Enable or disable use of SD-WAN as default service.
<code>set gateway [enable disable]</code>	Enable or disable SD-WAN service gateway.

By default, these settings are set to `disable`.

These two commands help adjust FortiGate route selection by affecting how the FortiGate consults the Forward Information Base (FIB).

In order to decide whether an SD-WAN policy-route can be matched, FortiGate performs the following FIB lookups:

- FIB best match for the destination must return an SD-WAN member.
- FIB route to the destination must exist over the desired SD-WAN member.

When `set default enable` is used with `set gateway enable`, FortiGate bypasses the FIB checks, and instead routes any matching traffic of the SD-WAN rule to the chosen SD-WAN member using the member's configured gateway. SD-WAN members must have a gateway configured.

When `set default disable` is used with `set gateway enable`, FortiGate keeps the first rule in effect but causes the second rule to change to:

- FIB route to the gateway IP address must exist over any interface.

See also [Fields for configuring WAN intelligence on page 771](#).

Implicit rule

SD-WAN rules define specific policy routing options to route traffic to an SD-WAN member. When no explicit SD-WAN rules are defined, or if none of the rules are matched, then the default implicit rule is used.

In an SD-WAN configuration, the default route usually points to the SD-WAN interface, so each active member's gateway is added to the routing table's default route. FortiOS uses equal-cost multipath (ECMP) to balance traffic between the interfaces. One of five load balancing algorithms can be selected:

Source IP (<code>source-ip-based</code>)	Traffic is divided equally between the interfaces, including the SD-WAN interface. Sessions that start at the same source IP address use the same path. This is the default selection.
Sessions (<code>weight-based</code>)	<p>The workload is distributing based on the number of sessions that are connected through the interface.</p> <p>The weight that you assign to each interface is used to calculate the percentage of the total sessions that are allowed to connect through an interface, and the sessions are distributed to the interfaces accordingly.</p> <p>The sessions with the same source and destination IP are forwarded to the same path if the device model and kernel version supports route cache. However, it is not guaranteed and the route cache could be refreshed in case network events take place. In most cases where route cache is not supported, the sessions with the same source and destination IP will be load balanced between SD-WAN member interfaces.</p> <p>An interface's weight value cannot be zero.</p>
Spillover (<code>usage-based</code>)	The interface is used until the traffic bandwidth exceeds the ingress and egress thresholds that you set for that interface. Additional traffic is then sent through the next SD-WAN interface member.
Source-Destination IP (<code>source-dest-ip-based</code>)	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address and go to the same destination IP address use the same path.

Volume (measured-volume-based)

The workload is distributing based on the number of packets that are going through the interface.

The volume weight that you assign to each interface is used to calculate the percentage of the total bandwidth that is allowed to go through an interface, and the bandwidth is distributed to the interfaces accordingly.

An interface's volume value cannot be zero.

You cannot exclude an interface from participating in load balancing using the implicit rule. If the weight or volume were set to zero in a previous FortiOS version, the value is treated as a one.

Interfaces with static routes can be excluded from ECMP if they are configured with a lower priority than other static routes.

Examples

The following four examples demonstrate how to use the implicit rules (load-balance mode).

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

Example 1

Outgoing traffic is equally balanced between wan1 and wan2, using *source-ip-based* or *source-dest-ip-based* mode.

Using the GUI:

1. On the FortiGate, enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 704](#) for details.
2. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab.
3. Edit the *sd-wan* rule (the last default rule).
4. For the *Load Balancing Algorithm*, select either *Source IP* or *Source-Destination IP*.
5. Click *OK*.

Using the CLI:

1. Enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 704](#) for details.
2. Set the load balancing algorithm:
Source IP based:

```
config system sdwan
    set load-balance-mode source-ip-based
end
```

Source-Destination IP based:

```
config system sdwan
    set load-balance-mode source-dest-ip-based
end
```

Example 2

Outgoing traffic is balanced between wan1 and wan2 with a customized ratio, using *weight-based* mode: wan1 runs 80% of the sessions, and wan2 runs 20% of the sessions.

Sessions with the same source and destination IP addresses (`src-ip` and `dst-ip`) will be forwarded to the same path, but will still be considered in later session ratio calculations.

Using the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab.
2. Edit the *sd-wan* rule (the last default rule).
3. For the *Load Balancing Algorithm*, select *Sessions*.
4. Enter 80 in the *wan1* field, and 20 in the *wan2* field.

Interface	Weight
to_ISP1 (wan1)	80
to_ISP2 (wan2)	20

80% wan1
20% wan2

5. Click **OK**.

Using the CLI:

```
config system sdwan
    set load-balance-mode weight-based
    config members
        edit 1
            set interface "wan1"
            set weight 80
        next
        edit 2
            set interface "wan2"
            set weight 20
        next
    end
end
```

Example 3

Outgoing traffic is balanced between wan1 and wan2 with a customized ratio, using *measured-volume-based* mode: wan1 runs 80% of the volume, and wan2 runs 20% of the volume.

Using the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab.
2. Edit the *sd-wan* rule (the last default rule).
3. For the *Load Balancing Algorithm*, select *Volume*.
4. Enter 80 in the *wan1* field, and 20 in the *wan2* field.
5. Click *OK*.

Using the CLI:

```
config system sdwan
    set load-balance-mode measured-volume-based
    config members
        edit 1
            set interface "wan1"
            set volume-ratio 80
        next
        edit 2
            set interface "wan2"
            set volume-ratio 20
        next
    end
end
```

Example 4

Load balancing can be used to reduce costs when internet connections are charged at different rates. For example, if wan2 charges based on volume usage and wan1 charges a fixed monthly fee, we can use wan1 at its maximum bandwidth, and use wan2 for overflow.

In this example, wan1's bandwidth is 10Mbps down and 2Mbps up. Traffic will use wan1 until it reaches its spillover limit, then it will start to use wan2. Note that *auto-asic-offload* must be disabled in the firewall policy.

Using the GUI:

1. On the FortiGate, enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 704](#) for details.
2. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab.
3. Edit the *sd-wan* rule (the last default rule).
4. For the *Load Balancing Algorithm*, select *Spillover*.

5. Enter 10000 in the *wan1 Ingress Spillover Threshold* field, and 2000 in the *wan1 Egress Spillover Threshold* field.

Interface	Ingress Spillover Threshold	Egress Spillover Threshold
to_ISP1 (wan1)	10000 kbps	2000 kbps
to_ISP2 (wan2)	0 kbps	0 kbps

 - Video Tutorials

OK Cancel

6. Click OK.

Using the CLI:

```
config system sdwan
    set load-balance-mode usage-based
    config members
        edit 1
            set interface "wan1"
            set spillover-threshold 2000
            set ingress-spillover-threshold 10000
        next
    end
end
```

Automatic strategy

The automatic strategy is a legacy rule that lets you select an outgoing interface based on its performance ranking compared to the other SD-WAN interfaces. This is achieved by applying a performance SLA to rank the interfaces, and then selecting the desired rank.

In this example, you have three SD-WAN interfaces to three different ISPs that all go to the public internet. WAN1 is your highest quality link and should be reserved for business critical traffic. WAN2 and WAN3 are redundant backup links. You noticed one non-critical application is taking up a lot of bandwidth and want to prioritize it to the lowest quality link at any given time.

To configure automatic SD-WAN rules from the CLI:

```
config system sdwan
    config members
        edit 1
            set interface "wan1"
        next
        edit 2
            set interface "wan2"
        next
        edit 3
            set interface "wan3"
        next
    end
end
```

```

end
config health-check
    edit "non-critical application"
        set server "noncritical.application.com"
        set members 1 2 3
        config sla
            edit 1
                set latency-threshold 250
                set jitter-threshold 50
                set packetloss-threshold 3
            next
        end
    next
end
config service
    edit 1
        set name "non-critical application"
        set mode auto
        set quality-link 3
        set dst "non-critical-app-address-object"
        set health-check "non-critical application"
    next
end
end

```

The `auto` option is only available in the CLI. If you use the GUI to edit the rule, the `auto` option will be overwritten because you cannot select `auto` in the GUI.

Manual strategy

In manual mode, no health checks are used. As a result, the decision making closer resembles logic than intelligence. SD-WAN manual rules are similar to regular policy-based routes, but have the added features of application-aware routing and BGP-tag routing. A manual strategy rule is comprised of the following parts:

- Defining the interfaces to be used
- Ordering the interfaces based on preference, or load balancing traffic out of the specified interfaces using a load balancing algorithm

The maximize bandwidth (`load-balance`) strategy used prior to FortiOS 7.4.1 is now known as the load balancing strategy. This strategy can be configured under the manual mode and the lowest cost (SLA) strategies.

- When the load balancing strategy is configured under the manual mode strategy, SLA targets are not used.
- When the load balancing strategy is configured under the lowest cost (SLA) strategy, SLA targets are used.

To configure manual SD-WAN rules from the GUI:

1. Go to *Network > SD-WAN*.
2. Select the *SD-WAN Rules* tab, and click *Create New*.

3. Set the following options to create a manual rule:

Name	Type a name for the rule.
Source	(Optional) Specify a <i>Source address</i> and/or <i>User group</i> .
Destination	Specify the destination using an <i>Address</i> object or an <i>Internet Service</i> or an <i>Application</i> .
Zone preference	Specify one or more SD-WAN interfaces or zones. The order in which the interfaces or zones are specified determines their priority when the rule is matched.

4. Set the remaining options as desired, and click *OK* to create the rule.

To configure manual SD-WAN rules from the CLI:

```
config system sdwan
  config members
    edit 1
      set interface "wan1"
    next
    edit 2
      set interface "wan2"
    next
  end
  config service
    edit 1
      set name "manual"
      set mode manual
      set priority-members 2 1
      set dst "DC_net"
      set hold-down-time 60
    next
  end
end
```

- The command `set mode manual` will not appear in the configuration because it is the default mode.
- The command `set hold-down-time <integer>` is an optional command that controls how long to wait before switching back to the primary interface in the event of a failover.

Load balancing strategy without SLA targets - NEW

The load balancing strategy known as maximize bandwidth (`load-balance`) prior FortiOS 7.4.1 is now configured within manual mode SD-WAN rules to achieve load balancing but without the need to configure SLA targets.

By enabling load balancing mode (`set load-balance enable`) inside the manual SD-WAN rule, SD-WAN will start to load balance traffic out of all the specified interfaces based on the configured load balancing algorithm. There is no explicit need to configure SLA targets to achieve load balancing. The load balancing algorithm, or hash method, can be one of the following:

round-robin	All traffic is distributed to selected interfaces in equal portions and circular order. This is the default method, and the only option available when using the GUI.
source-ip-based	All traffic from a source IP is sent to the same interface.
source-dest-ip-based	All traffic from a source IP to a destination IP is sent to the same interface.
inbandwidth	All traffic is distributed to a selected interface with most available bandwidth for incoming traffic.
outbandwidth	All traffic is distributed to a selected interface with most available bandwidth for outgoing traffic.
bibandwidth	All traffic is distributed to a selected interface with most available bandwidth for both incoming and outgoing traffic.

When the `inbandwidth`, `outbandwidth`, or `bibandwidth` load balancing algorithm is used, the FortiGate will compare the bandwidth based on the configured upstream and downstream bandwidth values.

The interface speedtest can be used to populate the bandwidth values based on the speedtest results. See [Manual interface speedtest on page 794](#) for details.

To manually configure the upstream and downstream bandwidth values:

```
config system interface
    edit <interface>
        set estimated-upstream-bandwidth <speed in kbps>
        set estimated-downstream-bandwidth <speed in kbps>
    next
end
```

To enable the load balancing strategy for manual mode in the GUI:

1. Go to *Network > SD-WAN*.
2. Select the *SD-WAN Rules* tab, and click *Create New*.
3. Set the *Interface selection strategy* to *Manual*.
4. Enable *Load balancing*.

5. Set the remaining options as desired, and click **OK** to create the rule.

To enable the load balancing strategy for manual mode in the CLI:

```
config system sdwan
...
config service
edit 1
set name "manual"
set mode manual
set load-balance enable
set hash-mode round-robin
set priority-members 2 1
set dst "DC_net"
set hold-down-time 60
next
end
end
```

Best quality strategy

When using **Best Quality** mode, SD-WAN will choose the best link to forward traffic by comparing the *link-cost-factor*. A link-cost factor is a specific metric of participating link(s) (such as, latency, packet loss, and so on) evaluated against a target that you define (such as a health-check server), for example, the latency of WAN1 and WAN2 to your datacenter. Below is a list of link-cost factors available to you:

GUI	CLI	Description
Latency	latency	Select a link based on latency.
Jitter	jitter	Select a link based on jitter.
Packet Loss	packet-loss	Select a link based on packet loss.
Downstream	inbandwidth	Select a link based on available bandwidth of incoming traffic.
Upstream	outbandwidth	Select a link based on available bandwidth of outgoing traffic.
Bandwidth	bibandwidth	Select a link based on available bandwidth of bidirectional traffic.
Customized profile	custom-profile-1	Select link based on customized profile. If selected, set the following weights: <ul style="list-style-type: none"> packet-loss-weight: Coefficient of packet-loss. latency-weight: Coefficient of latency. jitter-weight: Coefficient of jitter. bandwidth-weight: Coefficient of reciprocal of available bidirectional bandwidth.

Although SD-WAN intelligence selects the best quality link according to the selected metric, by default a preference or advantage is given to the first configured SD-WAN member. This default is 10% and may be configured with the CLI command `set link-cost-threshold 10`.

Example of how `link-cost-threshold` works:

```
config system sdwan
  config members
    edit 1
      set interface "wan1"
    next
    edit 2
      set interface "wan2"
    next
  end
  config service
    edit 1
      set name "Best_Quality"
      set mode priority
      set priority-members 2 1
      set dst "DC_net"
      set health-check "DC_HealthCheck"
      set link-cost-factor latency
      set link-cost-threshold 10
    next
  end
end
```

In this example both WAN1 and WAN2 are assumed to have 200ms latency to the health-check server named `DC_HealthCheck`. Because WAN2 is specified before WAN1 in `priority-members`, SD-WAN parses the two interfaces metric as follows:

- WAN1: 200ms
- WAN2: $200\text{ms} / (1+10\%) = \sim 182\text{ms}$

As a result, WAN2 is selected because the latency is lower.

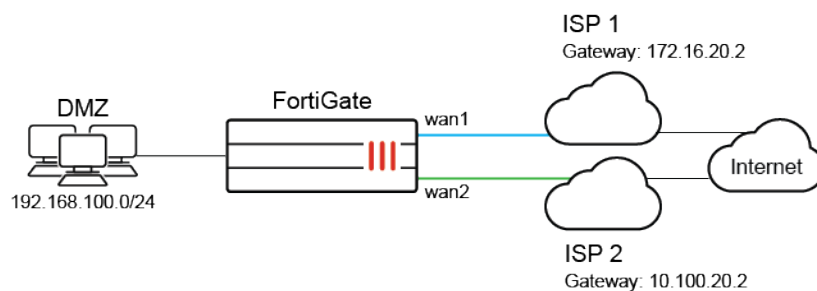

If the *Downstream* (inbandwidth), *Upstream* (outbandwidth), or *Bandwidth* (bibandwidth) quality criteria is used, the FortiGate uses the upstream and downstream bandwidth values configured on the member interfaces to calculate bandwidth.

The interface bandwidth configuration can be done manually, or the interface speedtest can be used to populate the bandwidth values based on the speedtest results. See [Manual interface speedtest on page 794](#) for details.

To manually configure the upstream and downstream interface bandwidth values:

```
config system interface
  edit <interface>
    set estimated-upstream-bandwidth <speed in kbps>
    set estimated-downstream-bandwidth <speed in kbps>
  next
end
```

Example

In this example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet, and you want Gmail services to use the link with the least latency.

To configure an SD-WAN rule to use Best Quality:

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 704](#) for more details.
2. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*. See [Health checks](#) for more details.
4. Click *OK*.
5. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
6. Enter a name for the rule, such as *gmail*.
7. Configure the following settings:

Internet Service	Google-Gmail
-------------------------	--------------

Strategy	Best Quality
-----------------	--------------

Interface preference	wan1 and wan2
-----------------------------	---------------

Measured SLA	google
---------------------	--------

Quality criteria	Latency
-------------------------	---------

8. Click OK.

To configure an SD-WAN rule to use priority:

```
config system sdwan
config health-check
    edit "google"
        set server "google.com"
        set members 1 2
    next
end
config service
    edit 1
        set name "gmail"
        set mode priority
        set internet-service enable
        set internet-service-id 65646
        set health-check "google"
```

```

        set link-cost-factor latency
        set priority-members 1 2
    next
end
end

```

To diagnose the Performance SLA status:

```
FGT # diagnose sys sdwan health-check google
```

```
Health Check(google):
```

```
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
```

```
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0
```

```
FGT # diagnose sys sdwan service 1
```

```
Service(1):
```

```

TOS(0x0/0x0), protocol(0: 1->65535), Mode(priority), link-cost-facotr(latency), link-
cost-threshold(10), health-check(google) Members:

```

```
1: Seq_num(2), alive, latency: 12.633, selected
```

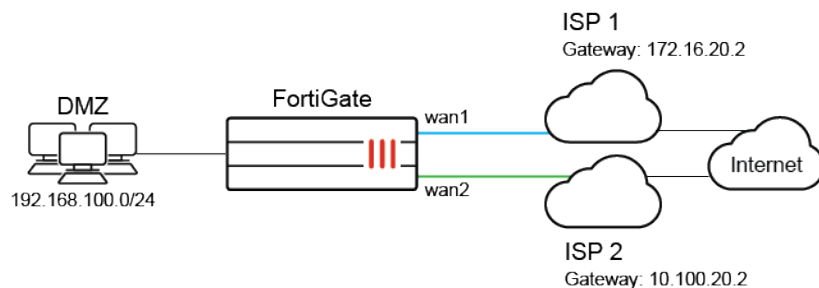

```
2: Seq_num(1), alive, latency: 14.563, selected
```

```
Internet Service: Google-Gmail(65646)
```

As wan2 has a smaller latency, SD-WAN will put Seq_num(2) on top of Seq_num(1) and wan2 will be used to forward Gmail traffic.

Lowest cost (SLA) strategy

When using *Lowest Cost (SLA)* mode (`sla` in the CLI), SD-WAN will choose the lowest cost link that satisfies SLA to forward traffic. The lowest possible cost is 0. If multiple eligible links have the same cost, the *Interface preference* order will be used to select a link.

In this example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet. The cost of wan2 is less than that of wan1. You want to configure Gmail services to use the lowest cost interface, but the link quality must meet a standard of latency: 10ms, and jitter: 5ms.

To configure an SD-WAN rule to use Lowest Cost (SLA):

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 704](#) for details.
2. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*.

4. Enable *SLA Target*. Set the *Latency threshold* to *10 ms*, and the *Jitter threshold* to *5 ms*. See [Health checks](#) for more details.
5. Click **OK**.
6. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
7. Enter a name for the rule, such as *gmail*.
8. Configure the following settings:

Internet Service	Google-Gmail
Strategy	Lowest Cost (SLA)
Interface preference	wan1 and wan2
Required SLA target	google

9. Click **OK**.

To configure an SD-WAN rule to use SLA:

```
config system sdwan
  config members
    edit 1
      set interface "wan1"
```

```

        set cost 10
    next
    edit 2
        set interface "wan2"
        set cost 5
    next
end
config health-check
    edit "google"
        set server "google.com"
        set members 1 2
        config sla
            edit 1
                set latency-threshold 10
                set jitter-threshold 5
            next
        end
    next
end
config service
    edit 1
        set name "gmail"
        set mode sla
        set internet-service enable
        set internet-service-id 65646
        config sla
            edit "google"
                set id 1
            next
        end
        set priority-members 1 2
    next
end
end

```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

The CLI command `set minimum-sla-meet-members` allows you to specify the number of links that must meet SLA for the rule to take effect. If the number of members is less than the minimum set with this command, the rule will not take effect.

To diagnose the performance SLA status:

```
FGT # diagnose sys sdwan health-check status
```

```
Health Check(google):
```

```
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
```

```
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0
```

```
FGT # diagnose sys sdwan service 1
```

```
Service(1): Address Mode(IPV4) flags=0x0
```

```
TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla)
Members:<<BR>>

1: Seq_num(2), alive, sla(0x1), cfg_order(1), selected
2: Seq_num(1), alive, sla(0x1), cfg_order(0), selected

Internet Service: Google.Gmail(65646)
```

When both wan1 and wan2 meet the SLA requirements, Gmail traffic will only use wan2. If only wan1 meets the SLA requirements, Gmail traffic will only use wan1, even though it has a higher cost. If neither interface meets the requirements, wan2 will be used.

If both interface had the same cost and both met the SLA requirements, the first link configured in `set priority-members` would be used.

Load balancing strategy with SLA targets - NEW

SD-WAN rules can be configured to load balance traffic out of all the interfaces that satisfy the SLA target.

The load balancing strategy known as maximize bandwidth (`load-balance`) prior FortiOS 7.4.1 is now configured within *Lowest Cost (SLA)* mode (`sla`) SD-WAN rules.

By enabling load balancing mode (`set load-balance enable`) inside the lowest cost SD-WAN rule, SD-WAN will choose all of the links that satisfy the SLA target to forward traffic based on a load balancing algorithm. The load balancing algorithm, or hash method, can be one of the following:

<code>round-robin</code>	All traffic is distributed to selected interfaces in equal portions and circular order. This is the default method, and the only option available when using the GUI.
<code>source-ip-based</code>	All traffic from a source IP is sent to the same interface.
<code>source-dest-ip-based</code>	All traffic from a source IP to a destination IP is sent to the same interface.
<code>inbandwidth</code>	All traffic is distributed to a selected interface with most available bandwidth for incoming traffic.
<code>outbandwidth</code>	All traffic is distributed to a selected interface with most available bandwidth for outgoing traffic.
<code>bibandwidth</code>	All traffic is distributed to a selected interface with most available bandwidth for both incoming and outgoing traffic.

When the `inbandwidth`, `outbandwidth`, or `bibandwidth` load balancing algorithm is used, the FortiGate will compare the bandwidth based on the configured upstream and downstream bandwidth values.

The interface speedtest can be used to populate the bandwidth values based on the speedtest results. See [Manual interface speedtest on page 794](#) for details.

To manually configure the upstream and downstream bandwidth values:

```
config system interface
edit <interface>
set estimated-upstream-bandwidth <speed in kbps>
set estimated-downstream-bandwidth <speed in kbps>
```

```

next
end

```

Example

Based on the same topology as the preceding example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet. You want to configure Gmail services to use both of the interface, but the link quality must meet a standard of latency: 10ms, and jitter: 5ms. This can maximize the bandwidth usage by using load balancing.

To configure an SD-WAN rule to use load balancing with SLA targets in the GUI:

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 704](#) for details.
2. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*.
4. Enable *SLA Target*. Set the *Latency threshold* to *10 ms*, and the *Jitter threshold* to *5 ms*. See [Health checks](#) for more details.
5. Click *OK*.
6. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
7. Enter a name for the rule, such as *gmail*.
8. Configure the following settings:

Priority Rule

Settings Info

Source

Address +

User group +

Destination

Address +

Internet service Google-Gmail +

Outgoing Interfaces

Interface selection strategy

☐ Manual
Manually assign outgoing interfaces.

☐ Best quality
The interface with the best measured performance is selected.

☒ Lowest cost (SLA)
The interface that meets SLA targets is selected. When there is a tie, the interface with the lowest assigned cost is selected.

Interface preference

to_ISP1 (wan1) X

to_ISP2 (wan2) X

+

Zone preference +

Measured SLA

Forward DSCP ☐

Reverse DSCP ☐

OK Cancel

Internet Service	Google-Gmail
Strategy	Lowest Cost (SLA)
Interface preference	wan1 and wan2
Required SLA target	google
Load balancing	Enable this setting

9. Click OK.

To configure an SD-WAN rule to use load balancing with SLA targets in the CLI:

```
config system sdwan
  config members
    edit 1
      set interface "wan1"
      set cost 10
    next
    edit 2
      set interface "wan2"
      set cost 5
    next
  end
  config health-check
    edit "google"
      set server "google.com"
      set members 1 2
      config sla
        edit 1
          set latency-threshold 10
          set jitter-threshold 5
        next
      end
    next
  end
  config service
    edit 1
      set name "gmail"
      set load-balance enable
      set mode sla
      set internet-service enable
      set internet-service-name "Google-Gmail"
      config sla
        edit "google"
          set id 1
        next
      end
      set priority-members 1 2
    next
  end
end
```

To diagnose the performance SLA status:

```

FGT # diagnose sys sdwan health-check status
Health Check(google):
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0

FGT # diagnose sys sdwan service 1
Service(1): Address Mode(IPV4) flags=0x0

TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance)
Members:<<BR>>

1: Seq_num(1), alive, sla(0x1), num of pass(1), selected
2: Seq_num(2), alive, sla(0x1), num of pass(1), selected

Internet Service: Google.Gmail(65646)

```

When both wan1 and wan2 meet the SLA requirements, Gmail traffic will use both wan1 and wan2. If only one of the interfaces meets the SLA requirements, Gmail traffic will only use that interface.

If neither interface meets the requirements but the `health-check` is still alive, then wan1 and wan2 tie. The traffic will try to balance between wan1 and wan2, using both interfaces to forward traffic.

The maximize bandwidth (`load-balance`) strategy used prior to FortiOS 7.4.1 is now known as the load balancing strategy. This strategy can be configured under the manual mode and the lowest cost (SLA) strategies.

- When the load balancing strategy is configured under the manual mode strategy, SLA targets are not used.
- When the load balancing strategy is configured under the lowest cost (SLA) strategy, SLA targets are used.

The load balancing strategy functionality remains the same as the maximum bandwidth (SLA) strategy when it is configured inside the lowest cost (SLA) strategy: load balance traffic out of all the interfaces that satisfy the SLA targets. Interface cost is not considered when selecting the best path when the load balancing strategy is used.

Load balancing strategy - NEW

The maximize bandwidth (`load-balance`) strategy used prior to FortiOS 7.4.1 is now known as the load balancing strategy. This strategy can be configured under the manual mode and the lowest cost (SLA) strategies.

- When the load balancing strategy is configured under the manual mode strategy, SLA targets are not used (see [Load balancing strategy without SLA targets](#) for an example configuration).
- When the load balancing strategy is configured under the lowest cost (SLA) strategy, SLA targets are used (see [Load balancing strategy with SLA targets](#) for an example configuration).

The load balancing strategy functionality remains the same as the maximum bandwidth (SLA) strategy when it is configured inside the lowest cost (SLA) strategy: load balance traffic out of all the interfaces that satisfy the SLA targets. Interface cost is not considered when selecting the best path when the load balancing strategy is used.

Manual interface speedtest

An interface speedtest can be manually performed on WAN interfaces in the GUI. The results of the test can be added to the interface's *Estimated bandwidth*. The estimated upstream and downstream bandwidths can be used in SD-WAN service rules to determine the best link to use when either Maximize Bandwidth or Best Quality strategies are selected.

An SD-WAN Network Monitor license is required to use the speedtest. The *System > FortiGuard* page show the license status.

FortiGuard Distribution Network			Service	Traffic Volume (Last 24 hours)
Intrusion Prevention	✓ Licensed (Expiration Date: 2023/10/21)		FortiCare	0 B
AntiVirus	✓ Licensed (Expiration Date: 2023/10/21)		FortiGate Cloud Log	0 B
Web Filtering	✓ Licensed (Expiration Date: 2023/10/21)		FortiGuard.com	633.97 kB
Outbreak Prevention	✓ Licensed (Expiration Date: 2023/10/21)		FortiGuard Download	96.92 MB
SD-WAN Network Monitor	✓ Licensed (Expiration Date: 2023/10/21)		FortiGuard Query	47.89 kB
Industrial DB	✓ Licensed (Expiration Date: 2023/10/21)		FortiGate Cloud Sandbox	0 B
IoT Detection Service	✓ Licensed (Expiration Date: 2023/10/21)			

To run an interface speedtest in the GUI:

1. Go to *Network > Interfaces*.
2. Edit a WAN interface. The interfaces can be grouped by role using the grouping dropdown on the right side of the toolbar.
3. Click *Execute speed test* in the right pane.

4. When the test completes, click *OK* in the *Confirm* pane to apply the results to the estimated bandwidth. The results can also be applied later by clicking *Apply results to estimated bandwidth*. The speedtest results are used to populate the *Estimated bandwidth* fields.
5. Click *OK*.

The FortiGate must be connected to FortiGuard, and able to reach either the AWS or Google speedtest servers.

Scheduled interface speedtest

The SD-WAN Network Monitor service supports running a speed test based on a schedule. The test results are automatically updated in the `measured-upstream-bandwidth` and `measured-downstream-bandwidth` fields. These fields do not impact the interface inbound bandwidth, outbound bandwidth, estimated upstream bandwidth, or estimated downstream bandwidth settings.

An SD-WAN Network Monitor license is required to use the speedtest. The *Licenses* widget and the *System > FortiGuard* page show the license status.

When the scheduled speed tests run, it is possible to temporarily bypass the bandwidth limits set on the interface and configure custom maximum or minimum bandwidth limits. These configurations are optional.

```
config system speed-test-schedule
  edit <interface>
    set schedules <schedule> ...
    set update-inbandwidth enable {enable | disable}
    set update-outbandwidth enable {enable | disable}
    set update-inbandwidth-maximum <integer>
    set update-inbandwidth-minimum <integer>
    set update-outbandwidth-maximum <integer>
    set update-outbandwidth-minimum <integer>
  next
end
```

update-inbandwidth enable {enable disable}	Enable/disable bypassing the interface's inbound bandwidth setting.
update-outbandwidth enable {enable disable}	Enable/disable bypassing the interface's outbound bandwidth setting.
update-inbandwidth- maximum <integer>	Maximum downloading bandwidth to be used in a speed test, in Kbps (0 - 16776000).
update-inbandwidth- minimum <integer>	Minimum downloading bandwidth to be considered effective, in Kbps (0 - 16776000).
update-outbandwidth- maximum <integer>	Maximum uploading bandwidth to be used in a speed test, in Kbps (0 - 16776000).
update-outbandwidth- minimum <integer>	Minimum uploading bandwidth to be considered effective, in Kbps (0 - 16776000).

In the following example, a speed test is scheduled on port1 at 10:00 AM, and another one at 14:00 PM.

To run a speed test based on a schedule:

1. Configure the recurring schedules:

```
config firewall schedule recurring
  edit "10"
    set start 10:00
    set end 12:00
    set day monday tuesday wednesday thursday friday
  next
  edit "14"
```

```

        set start 14:00
        set end 16:00
        set day monday tuesday wednesday thursday friday
    next
end

```

2. Configure the speed test schedule:

```

config system speed-test-schedule
    edit "port1"
        set schedules "10" "14"
        set update-inbandwidth enable
        set update-outbandwidth enable
        set update-inbandwidth-maximum 60000
        set update-inbandwidth-minimum 10000
        set update-outbandwidth-maximum 50000
        set update-outbandwidth-minimum 10000
    next
end

```

3. View the speed test results:

```

config system interface
    edit port1
        get | grep measure
        measured-upstream-bandwidth: 23691
        measured-downstream-bandwidth: 48862
        bandwidth-measure-time: Wed Jan 27 14:00:39 2021
    next
end

```

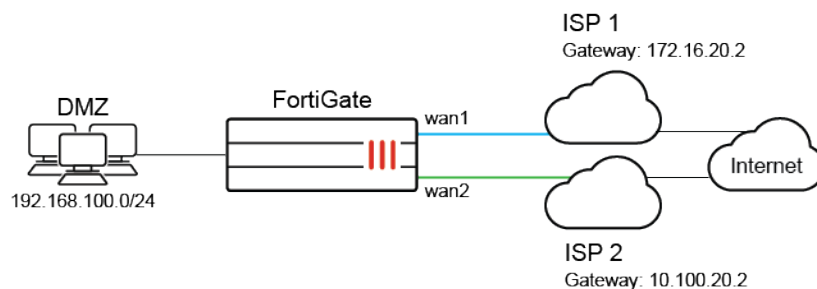

SD-WAN traffic shaping and QoS

Use a traffic shaper in a firewall shaping policy to control traffic flow. You can use it to control maximum and guaranteed bandwidth, or put certain traffic to one of the three different traffic priorities: high, medium, or low.

An advanced shaping policy can classify traffic into 30 groups. Use a shaping profile to define the percentage of the interface bandwidth that is allocated to each group. Each group of traffic is shaped to the assigned speed limit based on the outgoing bandwidth limit configured on the interface.

For more information, see [Traffic shaping on page 1341](#).

Sample topology

Sample configuration

This example shows a typical customer usage where the customer's SD-WAN uses the default zone, and has two member: wan1 and wan2, each set to 10Mb/s.

An overview of the procedures to configure SD-WAN traffic shaping and QoS with SD-WAN includes:

1. Give HTTP/HTTPS traffic high priority and give FTP low priority so that if there are conflicts, FortiGate will forward HTTP/HTTPS traffic first.
2. Even though FTP has low priority, configure FortiGate to give it a 1Mb/s guaranteed bandwidth on each SD-WAN member so that if there is no FTP traffic, other traffic can use all the bandwidth. If there is heavy FTP traffic, it can still be guaranteed a 1Mb/s bandwidth.
3. Traffic going to specific destinations such as a VOIP server uses wan1 to forward, and SD-WAN forwards with an Expedited Forwarding (EF) DSCP tag 101110.

To configure SD-WAN traffic shaping and QoS with SD-WAN in the GUI:

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route.
See [SD-WAN quick start on page 704](#).
2. Add a firewall policy with *Application Control* enabled. See [Configuring firewall policies for SD-WAN on page 707](#).
3. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shapers* tab, and edit *low-priority*.
 - a. Enable *Guaranteed Bandwidth* and set it to 1000 kbps.
4. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shaping Policies* tab, and click *Create New*.
 - a. Name the traffic shaping policy, for example, *HTTP-HTTPS*.
 - b. Set the following:

Source	<i>all</i>
Destination	<i>all</i>
Service	<i>HTTP and HTTPS</i>
Outgoing interface	<i>virtual-wan-link</i>
Shared Shaper	Enable and set to <i>high-priority</i>
Reverse Shaper	Enable and set to <i>high-priority</i>

- c. Click *OK*.
5. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shaping Policies* tab, and click *Create New*.
 - a. Name the traffic shaping policy, for example, *FTP*.
 - b. Set the following:

Source	<i>all</i>
Destination	<i>all</i>
Service	<i>FTP, FTP_GET, and FTP_PUT</i>
Outgoing interface	<i>virtual-wan-link</i>
Shared Shaper	Enable and set to <i>low-priority</i>
Reverse Shaper	Enable and set to <i>low-priority</i>

- c. Click *OK*

6. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
 - a. Enter a name for the rule, such as *Internet*.
 - b. In the *Destination* section, click *Address* and select the VoIP server that you created in the firewall address.
 - c. Under *Outgoing Interfaces* select *Manual*.
 - d. For *Interface preference* select *wan1*.
 - e. Click *OK*.
7. Use CLI commands to modify DSCP settings. See the DSCP CLI commands below.

To configure the firewall policy using the CLI:

```
config firewall policy
  edit 1
    set name "1"
    set srcintf "dmz"
    set dstintf "virtual-wan-link"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set ssl-ssh-profile "certificate-inspection"
    set application-list "default"
    set nat enable
  next
end
```

To configure the firewall traffic shaper priority using the CLI:

```
config firewall shaper traffic-shaper
  edit "high-priority"
    set maximum-bandwidth 1048576
    set per-policy enable
  next
  edit "low-priority"
    set guaranteed-bandwidth 1000
    set maximum-bandwidth 1048576
    set priority low
    set per-policy enable
  next
end
```

To configure the firewall traffic shaping policy using the CLI:

```
config firewall shaping-policy
  edit 1
    set name "http-https"
    set service "HTTP" "HTTPS"
    set dstintf "virtual-wan-link"
    set traffic-shaper "high-priority"
    set traffic-shaper-reverse "high-priority"
    set srcaddr "all"
    set dstaddr "all"
  next
```

```

edit 2
    set name "FTP"
    set service "FTP" "FTP_GET" "FTP_PUT"
    set dstintf "virtual-wan-link"
    set traffic-shaper "low-priority"
    set traffic-shaper-reverse "low-priority"
    set srcaddr "all"
    set dstaddr "all"
next
end

```

To configure SD-WAN traffic shaping and QoS with SD-WAN in the CLI:

```

config system sdwan
    set status enable
    config members
        edit 1
            set interface "wan1"
            set gateway 172.16.20.2
        next
        edit 2
            set interface "wan2"
            set gateway 10.100.20.2
        next
    end
    config service
        edit 1
            set name "SIP"
            set priority-members 1
            set dst "voip-server"
            set dscp-forward enable
            set dscp-forward-tag 101110
        next
    end
end

```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To use the diagnose command to check if specific traffic is attached to the correct traffic shaper:

```

# diagnose firewall iprope list 100015

policy index=1 uuid_idx=0 action=accept
flag (0):
shapers: orig=high-priority(2/0/134217728) reply=high-priority(2/0/134217728)

```

SDN dynamic connector addresses in SD-WAN rules

SDN dynamic connector addresses can be used in SD-WAN rules. FortiGate supports both public (AWS, Azure, GCP, OCI, AliCloud) and private (Kubernetes, VMware ESXi and NSX, OpenStack, ACI, Nuage) SDN connectors.

The configuration procedure for all of the supported SDN connector types is the same. This example uses an Azure public SDN connector.

There are four steps to create and use an SDN connector address in an SD-WAN rule:

1. Configure the FortiGate IP address and network gateway so that it can reach the Internet.
2. [Create an Azure SDN connector.](#)
3. [Create a firewall address to associate with the configured SDN connector.](#)
4. [Use the firewall address in an SD-WAN service rule.](#)

To create an Azure SDN connector:

1. Go to *Security Fabric > External Connectors*.
2. Click *Create New*.
3. In the *Public SDN* section, click *Microsoft Azure*.
4. Enter the following:

Name	azure1
Status	Enabled
Update Interval	Use Default
Server region	Global
Directory ID	942b80cd-1b14-42a1-8dcf-4b21dece61ba
Application ID	14dbd5c5-307e-4ea4-8133-68738141feb1
Client secret	xxxxxx
Resource path	disabled

5. Click *OK*.

To create a firewall address to associate with the configured SDN connector:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Enter the following:

Category	Address
Name	azure-address
Type	Dynamic
Sub Type	Fabric Connector Address
SDN Connector	azure1
SDN address type	Private
Filter	SecurityGroup=edsouza-centos
Interface	Any

4. Click **OK**.

To use the firewall address in an SD-WAN service rule:

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Set the *Name* to *Azure1*.
3. For the *Destination Address* select *azure-address*.
4. Configure the remaining settings as needed. See [SD-WAN rules on page 766](#) for details.
5. Click **OK**.

Diagnostics

Use the following CLI commands to check the status of and troubleshoot the connector.

To see the status of the SDN connector:

```
# diagnose sys sdn status
```

SDN Connector	Type	Status	Updating	Last update
-----	-----	-----	-----	-----
azure1	azure	connected	no	n/a

To debug the SDN connector to resolve the firewall address:

```
# diagnose debug application azd -1
Debug messages will be on for 30 minutes.

...
azd sdn connector azure1 start updating IP addresses
azd checking firewall address object azure-address-1, vd 0
IP address change, new list:
10.18.0.4
10.18.0.12
...
...

# diagnose sys sdwan service

Service(2): Address Mode(IPV4) flags=0x0
TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Service role: standalone
```

```
Member sub interface:
Members:
  1: Seq_num(1), alive, selected
Dst address:
  10.18.0.4 - 10.18.0.4
  10.18.0.12 - 10.18.0.12
  ... ..
  ... ..
  ... ..
```

Application steering using SD-WAN rules

This topic covers how to use application steering in a topology with multiple WAN links. The following examples illustrate how to use different strategies to perform application steering to accommodate different business needs:

- [Application matching on page 804](#)
- [Static application steering with a manual strategy on page 805](#)
- [Dynamic application steering with lowest cost and best quality strategies on page 808](#)

By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System > Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
  set gui-app-detection-sdwan enable
end
```

For application based steering to work, application control must be enabled in a policy. See [Application control on page 1558](#).

Application matching

To apply application steering, SD-WAN service rules match traffic based on the applications that are in the application signature database. To view the signatures, go to *Security Profiles > Application Signatures* and select *Signature*.

On the first session that passes through, the IPS engine processes the traffic in the application layer to match it to a signature in the application signature database. The first session does not match any SD-WAN rules because the signature has not been recognized yet. When the IPS engine recognizes the application, it records the 3-tuple IP address, protocol, and port in the application control Internet Service ID list. To view the application and corresponding 3-tuple:

```
# diagnose sys sdwan internet-service-app-ctrl-list [app ID]
52.114.142.254
Microsoft.Teams (43541 4294837333): 52.114.142.254 6 443 Fri Jun 18 13:52:18 2021
```

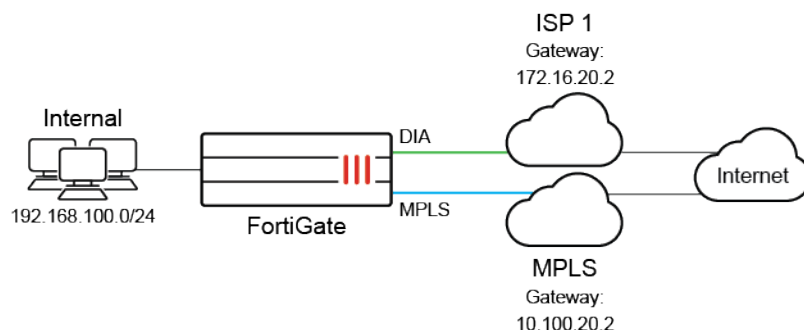

The recognized application and 3-tuple stay in the application control list for future matches to occur. If there are no hits on the entry for eight hours, the entry is deleted.

For services with multiple IP addresses, traffic might not match the expected SD-WAN rule because the traffic is destined for an IP address that has not previously been recognized by the FortiGate. The `diagnose sys sdwan internet-service-app-ctrl-list` command can be used to help troubleshoot such situations.

Static application steering with a manual strategy

This example covers a typical usage scenario where the SD-WAN has two members: MPLS and DIA. DIA is primarily used for direct internet access to internet applications, such as Office365, Google applications, Amazon, and Dropbox. MPLS is primarily used for SIP, and works as a backup when DIA is not working.

This example configures all SIP traffic to use MPLS while all other traffic uses DIA. If DIA is not working, the traffic will use MPLS.

By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System > Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
    set gui-app-detection-sdwan enable
end
```

To configure an SD-WAN rule to use SIP and DIA in the GUI:

1. Add port1 (DIA) and port2 (MPLS) as SD-WAN members, and configure a static route. See [Configuring the SD-WAN interface on page 704](#) for details.
2. Create a firewall policy with an *Application Control* profile configured. See [Configuring firewall policies for SD-WAN on page 707](#) for details.
3. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
4. Enter a name for the rule, such as *SIP*.
5. Click the *Application* field and select the applicable SIP applications from the *Select Entries* panel.
6. Under *Outgoing Interfaces*, select *Manual*.
7. For *Interface preference*, select *MPLS*.
8. Click *OK*.
9. Click *Create New* to create another rule.
10. Enter a name for the rule, such as *Internet*.
11. Click the *Address* field and select *all* from the panel.
12. Under *Outgoing Interfaces*, select *Manual*.
13. For *Interface preference*, select *DIA*.
14. Click *OK*.

To configure the firewall policy using the CLI:

```
config firewall policy
    edit 1
        set name "1"
        set srcintf "dmz"
        set dstintf "virtual-wan-link"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set fsso disable
        set application-list "default"
        set ssl-ssh-profile "certificate-inspection"
        set nat enable
    next
end
```

To configure an SD-WAN rule to use SIP and DIA using the CLI:

```

config system sdwan
    set status enable
    config members
        edit 1
            set interface "MPLS"
        next
        edit 2
            set interface "DIA"
        next
    end
    config service
        edit 1
            set name "SIP"
            set internet-service enable
            set internet-service-app-ctrl 34640 152305677 38938 26180 26179 30251
            set priority-members 2
        next
        edit 2
            set name "Internet"
            set dst "all"
            set priority-members 1
        next
    end
end

```

All SIP traffic uses MPLS. All other traffic goes to DIA. If DIA is broken, the traffic uses MPLS. If you use VPN instead of MPLS to run SIP traffic, you must configure a VPN interface, for example vpn1, and then replace member 1 from MPLS to vpn1 for SD-WAN member.

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To use the diagnose command to check performance SLA status using the CLI:

```

# diagnose sys sdwan service 1

Service(1): Address Mode(IPV4) flags=0x0

TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members:<<BR>>

1: Seq_num(1), alive, selected

Internet Service: SIP(4294836224 34640) SIP.Method(4294836225 152305677) SIP.Via.NAT
(4294836226 38938) SIP_Media.Type.Application(4294836227 26180) SIP_Message(4294836228
26179) SIP_Voice(4294836229 30251)

# diagnose sys sdwan service 2

Service(2): Address Mode(IPV4) flags=0x0

TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)

```

Members:<
>

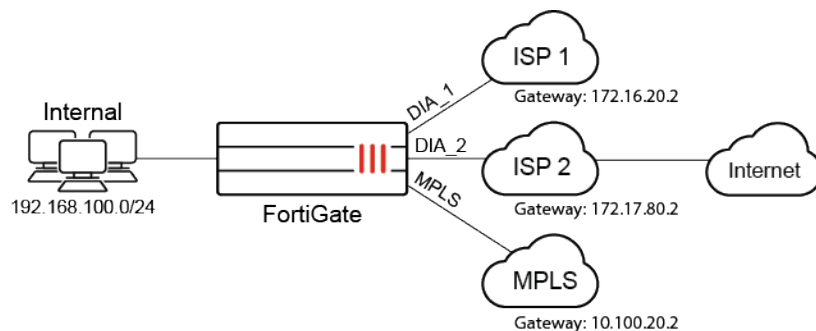

1: Seq_num(2), alive, selected

Dst address: 0.0.0.0-255.255.255.255

```
# diagnose sys sdwan internet-service-app-ctrl-list
Ctrl application(SIP 34640):Internet Service ID(4294836224)
Ctrl application(SIP.Method 152305677):Internet Service ID(4294836225)
Ctrl application(SIP.Via.NAT 38938):Internet Service ID(4294836226)
Ctrl application(SIP_Media.Type.Application 26180):Internet Service ID(4294836227)
Ctrl application(SIP_Message 26179):Internet Service ID(4294836228)
Ctrl application(SIP_Voice 30251):Internet Service ID(4294836229)
```

Dynamic application steering with lowest cost and best quality strategies

In this example, the SD-WAN has three members: two ISPs (DIA_1 and DIA_2) that are used for access to internet applications, and an MPLS link that is used exclusively as a backup for business critical applications.

Business applications, such as Office365, Google, Dropbox, and SIP, use the *Lowest Cost (SLA)* strategy to provide application steering, and traffic falls back to MPLS only if both ISP1 and ISP2 are down. Non-business applications, such as Facebook and Youtube, use the *Best Quality* strategy to choose between the ISPs.

By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to **System > Feature Visibility** and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
    set gui-app-detection-sdwan enable
end
```

To configure the SD-WAN members, static route, and firewall policy in the GUI:

1. Add port1 (DIA_1), port2 (DIA_2), and port3 (MPLS) as SD-WAN members. Set the cost of DIA_1 and DIA_2 to 0, and MPLS to 20. See [Configuring the SD-WAN interface on page 704](#) for details.
2. Configure a static route. See [Adding a static route on page 706](#) for details.
3. Create a firewall policy to allow traffic out on SD-WAN, with an *Application Control* profile configured. See [Configuring firewall policies for SD-WAN on page 707](#) for details.

To configure the SD-WAN rule and performance SLA checks for business critical application in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.

2. Set the name to *BusinessCriticalApps*.

This rule will steer your business critical traffic to the appropriate link based on the *Lowest Cost (SLA)*.

3. Set *Source address* to *all*.

4. Under *Destination*, set *Application* to your required applications. In this example: *Microsoft.Office.365*, *Microsoft.Office.Online*, *Google.Docs*, *Dropbox*, and *SIP*.

5. Under *Outgoing Interfaces*, select *Lowest Cost (SLA)*.

The lowest cost is defined in the SD-WAN member interface settings (see [Configuring the SD-WAN interface on page 704](#)). The lowest possible cost is 0, which represents the most preferred link. In this example, DIA_1 and DIA_2 both have a cost of 0, while MPLS has a cost of 20 because it is used for backup.

6. In *Interface preference*, add the interfaces in order of preference when the cost of the links is tied. In this example, DIA_1, DIA_2, then MPLS.

MPLS will always be chosen last, because it has the highest cost. DIA_1 and DIA_2 have the same cost, so an interface is selected based on their order in the *Interface preference* list.

7. Set *Required SLA target* to ensure that only links that pass your SLA target are chosen in this SD-WAN rule:

- a. Click in the *Required SLA target* field.
- b. In the *Select Entries* pane, click *Create*. The *New Performance SLA* pane opens.
- c. Set *Name* to *BusinessCriticalApps_HC*.

This health check is used for business critical applications in your SD-WAN rule.

- d. Leave *Protocol* set to *Ping*, and add up to two servers, such as *office.com* and *google.com*.
- e. Set *Participants* to *Specify*, and add all three interfaces: DIA_1, DIA_2, and MPLS.
- f. Enable *SLA Target*.

The attributes in your target determine the quality of your link. The SLA target of each link is compared when determining which link to use based on the lowest cost. Links that meet the SLA target are preferred over links that fail, and move to the next step of selection based on cost. If no links meet the SLA target, then they all move to the next step.

In this example, disable *Latency threshold* and *Jitter threshold*, and set *Packet loss threshold* to 1.

- g. Click *OK*.
- h. Select the new performance SLA to set it as the *Required SLA target*.

When multiple SLA targets are added, you can choose which target to use in the SD-WAN rule.

OK Cancel

8. Click OK to create the SD-WAN rule.

To configure the SD-WAN rule and performance SLA checks for non-business critical application in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Set the name to *NonBusinessCriticalApps*.

This rule will steer your non-business critical traffic to the appropriate link based on the *Best Quality*. No SLA target must be met, as the best link is selected based on the configured quality criteria and interface preference order.

3. Set *Source address* to *all*.
4. Under *Destination*, set *Application* to your required applications. In this example: *Facebook*, and *Youtube*.
5. Under *Outgoing Interfaces*, select *Best Quality*.
6. In *Interface preference*, add the interfaces in order of preference.

By default, a more preferred link has an advantage of 10% over a less preferred link. For example, when latency is used, the preferred link's calculated latency = real latency / (1+10%).

The preferred link advantage can be customized in the CLI when the mode is `priority` (*Best Quality*) or `auto`:

```
config system sdwan
  config service
    edit <id>
      set link-cost-threshold <integer>
    next
  end
end
```

7. Create and apply a new performance SLA profile:

- a. Click in the *Measured SLA* field.
- b. In the drop-down list, click *Create*. The *New Performace SLA* pane opens.
- c. Set *Name* to *NonBusinessCritical_HC*.
This health check is used for non-business critical applications in your SD-WAN rule.
- d. Leave *Protocol* set to *Ping*, and add up to two servers, such as *youtube.com* and *facebook.com*.
- e. Set *Participants* to *Specify*, and add the *DIA_1* and *DIA_2* interfaces. In this example, MPLS is not used for non-business critical applications.
- f. Leave *SLA Target* disabled.
- g. Click *OK*.
- h. Select the new performance SLA from the list to set it as the *Measured SLA*.

8. Set *Quality criteria* as required. In this example, *Latency* is selected.

For bandwidth related criteria, such as *Downstream*, *Upstream*, and *Bandwidth* (bi-directional), the selection is based on available bandwidth. An estimated bandwidth should be configured on the interface to provide a baseline, maximum available bandwidth.

SD-WAN Rules Setup Guides

-
-
-
-

Documentation

-
-

9. Click OK to create the SD-WAN rule.

To configure the SD-WAN members, static route, and firewall policy in the CLI:

1. Configure the interfaces:

```
config system interface
    edit "port1"
        set ip <class_ip&net_netmask>
        set alias "DIA_1"
        set role wan
    next
    edit "port2"
        set ip <class_ip&net_netmask>
        set alias "DIA_2"
        set role wan
    next
    edit "port3"
        set ip <class_ip&net_netmask>
        set alias "MPLS"
        set role wan
    next
end
```

2. Configure the SD-WAN members:

```
config system sdwan
    set status enable
```

```

config members
    edit 1
        set interface "port1"
        set gateway 172.16.20.2
    next
    edit 2
        set interface "port2"
        set gateway 172.17.80.2
    next
    edit 3
        set interface "port3"
        set gateway 10.100.20.2
        set cost 20
    next
end
end

```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

3. Configure a static route. See [Adding a static route on page 706](#) for details.
4. Create a firewall policy to allow traffic out on SD-WAN, with an *Application Control* profile configured. See [Configuring firewall policies for SD-WAN on page 707](#) for details.

To configure the SD-WAN rule and performance SLA checks for business critical application in the CLI:

1. Configure the *BusinessCriticalApps_HC* health-check:

```

config system sdwan
    config health-check
        edit "BusinessCriticalApps_HC"
            set server "office.com" "google.com"
            set members 1 2 3
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 1
                next
            end
        next
    end
end
end

```

2. Configure the *BusinessCriticalApps* service to use *Lowest Cost (SLA)*:

```

config system sdwan
    config service
        edit 1
            set name "BusinessCriticalApps"
            set mode sla
            set src "all"
            set internet-service enable
            set internet-service-app-ctrl 17459 16541 33182 16177 34640
            config sla

```

```
        edit "BusinessCriticalApps_HC"
            set id 1
        next
    end
    set priority-members 1 2 3
next
end
end
```

To configure the SD-WAN rule and performance SLA checks for non-business critical application in the CLI:

1. Configure the *nonBusinessCriticalApps_HC* health-check:

```
config system sdwan
    config health-check
        edit "NonBusinessCriticalApps_HC"
            set server "youtube.com" "facebook.com"
            set members 1 2
        next
    end
end
```

2. Configure the *NonBusinessCriticalApps* service to use *Lowest Cost (SLA)*:

```
config system sdwan
    config service
        edit 4
            set name "NonBusinessCriticalApps"
            set mode priority
            set src "all"
            set internet-service enable
            set internet-service-app-ctrl 15832 31077
            set health-check "NonBusinessCriticalApps_HC"
            set priority-members 1 2
        next
    end
end
```

Verification

Check the following GUI pages, and run the following CLI commands to confirm that your traffic is being steered by the SD-WAN rules.

Health checks

To verify the status of each of the health checks in the GUI:

1. Go to **Network > SD-WAN**, select the **Performance SLAs** tab, and select each of the health checks from the list.

To verify the status of each of the health checks in the CLI:

```
# diagnose sys sdwan health-check
Health Check(BusinessCritical_HC):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(12.884), jitter(0.919) sla_map=0x1
Seq(2 port2): state(alive), packet-loss(0.000%) latency(13.018), jitter(0.723) sla_map=0x1
Seq(3 port3): state(alive), packet-loss(0.000%) latency(13.018), jitter(0.923) sla_map=0x1
Health Check(NonBusinessCritical_HC):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(6.888), jitter(0.953) sla_map=0x0
Seq(2 port2): state(alive), packet-loss(0.000%) latency(6.805), jitter(0.830) sla_map=0x0
```

Rule members and hit count

To verify the active members and hit count of the SD-WAN rule in the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab.

SD-WAN Zones SD-WAN Rules Performance SLAs						
<div> <div>+ Create New</div> <div>Edit</div> <div>Clone</div> <div>Delete</div> <div>Search</div> <div>Q</div> </div>						
ID	Name	Source	Destination	Criteria	Members	Hit Count
IPv4						
1	BusinessCriticalApps	all	Dropbox Google.Docs Microsoft.Office.365 Microsoft.Office.Online SIP	SLA	<div> <div>DIA_1 (port1)</div> <div>DIA_2 (port2)</div> <div>MPLS (port3)</div> </div>	45
4	NonBusinessCriticalApps	all	Facebook YouTube	Latency	<div> <div>DIA_1 (port1)</div> <div>DIA_2 (port2)</div> </div>	32
Implicit						
sd-wan	all	all	Source IP	any		
Updated: 04:05:32						

The interface that is currently selected by the rule has a checkmark next to its name in the *Members* column. Hover the cursor over the checkmark to open a tooltip that gives the reason why that member is selected. If multiple members are selected, only the highest ranked member is highlighted (unless the mode is *Maximize Bandwidth (SLA)*).

To verify the active members and hit count of the SD-WAN rule in the CLI:

```
# diagnose sys sdwan service
```

```

Applications and sessions

To verify sessions in FortiView:

1. Go to a dashboard and add the *FortiView Cloud Applications* widget sorted by bytes. See [Cloud application view on page 151](#) for details.

2. Drill down on an application, such as *YouTube*, then select the *Sessions* tab.

To verify applications identified by Application Control in SD-WAN:

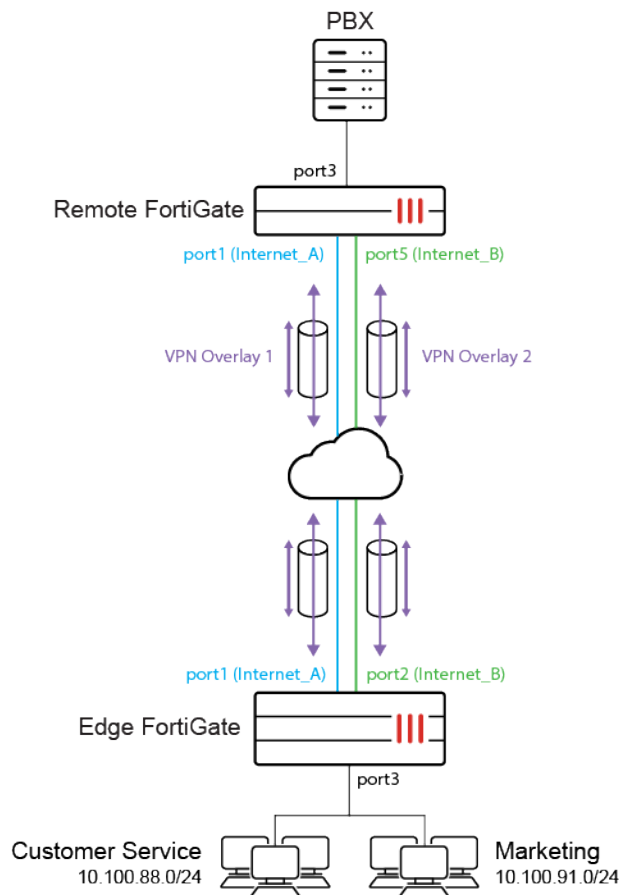

```
# diagnose sys sdwan internet-service-app-ctrl-list
```

```

DSCP tag-based traffic steering in SD-WAN

Differentiated Services Code Point (DSCP) tags can be used to categorize traffic for quality of service (QoS). SD-WAN traffic steering on an edge device can be provided based on the DSCP tags.

This section provides an example of using DSCP tag-based traffic steering using secure SD-WAN. Traffic from the customer service and marketing departments at a headquarters are marked with separate DSCP tags by the core switch and passed to the edge FortiGate. The edge FortiGate reads the tags, then steers traffic to the preferred interfaces based on the defined SD-WAN rules.

VoIP and social media traffic are steered. VoIP traffic from the customer service department is more important than social media traffic. The edge FortiGate identifies the tagged traffic based on SD-WAN rules then steers the traffic:

- VoIP traffic is marked with DSCP tag 011100 and steered to the VPN overlay with the lowest jitter, to provide the best quality voice communication with the remote PBX server.
- Social media traffic is marked with the DSCP tag 001100 and steered to the internet connection with the lowest cost.

The following is assumed to be already configured:

- Two IPsec tunnels ([IPsec VPNs on page 1765](#)):
 - Branch-HQ-A on Internet_A (port 1)
 - Branch-HQ-B on Internet_B (port 5)
- Four SD-WAN members in two zones ([Configuring the SD-WAN interface on page 704](#)):
 - Overlay zone includes members Branch-HQ-A and Branch-HQ-B
 - virtual-wan-link zone includes members Internet_A and Internet_B

Internet_A has a cost of 0 and Internet_B has a cost of 10. When using the lowest cost strategy, Internet_A will be preferred. Both members are participants in the Default_DNS performance SLA.
- A static route that points to the SD-WAN interface ([Adding a static route on page 706](#)).
- Two firewall policies:

Name	SD-WAN-OUT	Overlay-OUT
------	------------	-------------

From	port3	port3
To	virtual-wan-link	Overlay
Source	all	all
Destination	all	all
Schedule	always	always
Service	all	all
Action	Accept	Accept
NAT	enabled	enabled

After the topology is configured, you can proceed with the configuration of the edge FortiGate:

- [Configuring SD-WAN rules on page 819](#)
- [Results on page 821](#)

Configuring SD-WAN rules

Configure SD-WAN rules to govern the steering of DSCP tag-based traffic to the appropriate interfaces. Traffic is steered based on the criteria that are configured in the SD-WAN rules.

In this example, three SD-WAN rules are configured to govern DSCP tagged traffic:

- *VoIP-Steer* for [VoIP traffic](#).
- *Facebook-DSCP-steer* for [Social media traffic](#).
- *All-traffic* for all of the [Other web traffic](#).

After configuring the rules, go to *Network > SD-WAN* and select the *SD-WAN Rules* tab to check the rules.

VoIP traffic

VoIP traffic is steered to the *Overlay* zone.

DSCP values are usually 6-bit binary numbers that are padded with zeros at the end. VoIP traffic with DSCP tag 011100 will become 01110000. This 8-bit binary number is represented in its hexadecimal form, 0x70, as the type of service bit pattern (*tos*) value. The type of service evaluated bits (*tos-mask*) hexadecimal value of 0xf0 (11110000 in binary) is used to check the four most significant bits in the *tos* value. The four most significant bits of the *tos* (0111) are used to match the first four bits of the DSCP tag. Only the non-zero bit positions in the *tos-mask* are used for comparison; the zero bit positions are ignored.

The *Best quality* (*priority* mode) strategy is used to select the preferred interface, with the *Quality criteria* (*link-cost-members*) set to *Jitter*. The interface with the lowest amount of jitter is selected. For more information about configuring SD-WAN rules with the *Best Quality* strategy, see [Best quality strategy on page 783](#).

To configure the rule for DSCP tagged VoIP traffic using the CLI:

```
config sys sdwan
  config service
    edit 5
      set name "VoIP-Steer"
      set mode priority
```

```

        set tos 0x70
        set tos-mask 0xf0
        set dst "all"
        set health-check "Default_DNS"
        set link-cost-factor jitter
        set priority-members 4 3
    next
end
end

```

Social media traffic

Social media traffic is steered to the *virtual-wan-link* zone.

DSCP values are usually 6-bit binary numbers that are padded with zeros at the end. Social media traffic with DSCP tag 001100 will become 00110000. This 8-bit binary number is represented in its hexadecimal form, 0x30, as the `tos` value. The `tos-mask` hexadecimal value of 0xf0 (11110000 in binary) is used to check the four most significant bits in the `tos` value. The four most significant bits of the `tos` (0011) are used to match the first four bits of the DSCP tag. Only the non-zero bit positions in the `tos-mask` are used for comparison; the zero bit positions are ignored.

The *Manual* (manual mode) strategy is used to select the preferred interface. Internet_B (port5, priority member 2) is set as the preferred interface to steer all social media traffic to. For more information about configuring SD-WAN rules with the manual strategy, see [Manual strategy on page 780](#).

To configure SD-WAN rule for DSCP tagged social media traffic using the CLI:

```

config system sdwan
    config service
        edit 3
            set name "Facebook-DSCP-steer"
            set mode manual
            set tos 0x30
            set tos-mask 0xf0
            set dst "all"
            set priority-members 2 1
        next
    end
end

```

Other web traffic

Other web traffic is steered to the *virtual-wan-link* zone.

The *Lowest Cost (SLA)* strategy (`sla` mode) is used to select the preferred interface. The interface that meets the defined SLA targets (*Default_DNS* in this case) is selected. If there is a tie, the interface with the lowest cost is selected, Internet_A (port1) in this case.

For more information about configuring SD-WAN rules with the *Lowest Cost (SLA)* strategy, see [Lowest cost \(SLA\) strategy on page 787](#).

To configure SD-WAN rule for all other web traffic using the CLI:

```

config system sdwan
    config service
        edit 2

```

```

set name "All-traffic"
set mode sla
set dst "all"
config sla
    edit "Default_DNS"
        set id 1
    next
end
set priority-members 1 2
next
end
end

```

Results

These sections show the function of SD-WAN with respect to DSCP tagged traffic steering, and can help confirm that it is running as expected:

- [Verifying the DSCP tagged traffic on FortiGate on page 821](#)
- [Verifying the service rules on page 822](#)
- [Verifying traffic steering on the SD-WAN rules on page 823](#)
- [Verifying that steered traffic is leaving from the expected interface on page 823](#)

Verifying the DSCP tagged traffic on FortiGate

Packet sniffing is used to verify the incoming DSCP tagged traffic. See [Using the FortiOS built-in packet sniffer](#) for more information.

Wireshark is used to verify that VoIP traffic is tagged with the expected DSCP tag, 0x70 or 0x30.

VoIP traffic marked with DSCP tag 0x70:

```
# diagnose sniffer packet any '(ip and ip[1] & 0xfc == 0x70)' 601
```

The image shows a Wireshark packet capture interface. The top pane displays a list of captured packets. Packet 1 is selected, showing details of an Ethernet II frame, Internet Protocol Version 4, and User Datagram Protocol (UDP). The DSCP field in the IP header is highlighted with a red box, showing a value of 0x70 (DSCP: AF32, ECN: Not-ECT). The bottom pane shows the raw packet data in hexadecimal and ASCII.

Differentiated Services Field (p.d.sfield), 1 byte

Packets: 111 · Displayed: 111 (100.0%)

Profile: Default

Web traffic marked with DSCP tag 0x30:

```
# diagnose sniffer packet any '(ip and ip[1] & 0xfc == 0x30)' 6 0 1
```

Wireshark packet capture showing a TCP segment with DSCP tag 0x30. The packet list shows a SYN-ACK from 10.100.91.100 to 157.240.2.174. The packet details pane highlights the Differentiated Services Field (DSCP: AF12, ECN: Not-ECT) with a total length of 52 bytes. The packet bytes pane shows the hex representation of the packet header.

Verifying the service rules

To check that the expected DSCP tags and corresponding interfaces are used by the SD-WAN rules to steer traffic:

```
# diagnose sys sdwan service
```

```
Service(5): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x70/0xf0), Protocol(0: 1->65535), Mode(manual)
  Members:
    1: Seq_num(4 Branch-HQ-B), alive, selected
  Dst address:
    0.0.0.0-255.255.255.255
```

```
Service(3): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x30/0xf0), Protocol(0: 1->65535), Mode(manual)
  Members:
    1: Seq_num(2 port5), alive, selected
  Dst address:
    0.0.0.0-255.255.255.255
```

```
Service(2): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members:
    1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
    2: Seq_num(2 port5), alive, sla(0x1), cfg_order(1), cost(10), selected
  Dst address:
    0.0.0.0-255.255.255.255
```

Verifying traffic steering on the SD-WAN rules

Go to **Network > SD-WAN** and select the **SD-WAN Rules** tab to check the **Hit Count** on the SD-WAN interfaces.

Verifying that steered traffic is leaving from the expected interface

To confirm that web traffic (port 443) flows through the correct underlay interface members, and VoIP traffic flows through the correct overlay interface members, go to **Dashboard > FortiView Policies** and double click on the policy name.

Web traffic is expected to leave on **Interface_A (port1)** or **Interface_B (port5)**:

ECMP support for the longest match in SD-WAN rule matching

The longest match SD-WAN rule can match ECMP best routes. The rule will select the egress ports on ECMP specific routes, and not the less specific routes, to transport traffic.

The service mode determines which egress port on the ECMP specific routes is selected to forward traffic:

- Manual (`manual`): The first configured alive port is selected.
- Best Quality (`priority`): The best quality port is selected.
- Lowest Cost (`sla`): The first configured or lower cost port in SLA is selected.

Example

By default, SD-WAN selects the outgoing interface from all of the links that have valid routes to the destination. In some cases, it is required that only the links that have the best (or longest match) routes (single or ECMP) to the destination are considered.

In this example, four SD-WAN members in two zones are configured. The remote PC (PC_2 - 10.1.100.22) is accessible on port15 and port16, even though there are valid routes for all of the SD-WAN members. A single SD-WAN service rule is configured that allows traffic to be balanced between all four of the members, but only chooses between port15 and port16 for the specific 10.1.100.22 address.

A performance SLA health check is configured to monitor 10.1.100.2. An SD-WAN service rule in Lowest Cost (SLA) mode is configured to select the best interface to steer the traffic. In the rule, the method of selecting a member if more than one meets the SLA (`tie-break`) is configured to select members that meet the SLA and match the longest prefix in the routing table (`fib-best-match`). If there are multiple ECMP routes with the same destination, the FortiGate will take the longest (or best) match in the routing table, and choose from those interface members.

To configure the SD-WAN:

```
config system sdwan
  config zone
    edit "virtual-wan-link"
    next
    edit "z1"
    next
  end
  config members
    edit 1
      set interface "port1"
      set gateway 172.16.200.2
    next
    edit 2
      set interface "dmz"
      set gateway 172.16.208.2
    next
  end
end
```

```

edit 3
    set interface "port15"
    set zone "z1"
    set gateway 172.16.209.2
next
edit 4
    set interface "port16"
    set zone "z1"
    set gateway 172.16.210.2
next
end
config health-check
    edit "1"
        set server "10.1.100.2"
        set members 0
        config sla
            edit 1
            next
        end
    next
end
config service
    edit 1
        set name "1"
        set mode sla
        set dst "all"
        set src "172.16.205.0"
        config sla
            edit "1"
                set id 1
            next
        end
        set priority-members 1 2 3 4
        set tie-break fib-best-match
    next
end
end

```

To check the results:

1. The debug shows the SD-WAN service rule. All of the members meet SLA, and because no specific costs are attached to the members, the egress interface is selected based on the interface priority order that is configured in the rule:

```
FGT_A (root) # diagnose sys sdwan service
```

```

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(4), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Members(4):
  1: Seq_num(1 port1), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
  2: Seq_num(2 dmz), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
  3: Seq_num(3 port15), alive, sla(0x1), gid(0), cfg_order(2), cost(0), selected
  4: Seq_num(4 port16), alive, sla(0x1), gid(0), cfg_order(3), cost(0), selected
Src address(1):
  172.16.205.0-172.16.205.255

```

```
Dst address(1):
0.0.0.0-255.255.255.255
```

2. The routing table shows that there are ECMP default routes on all of the members, and ECMP specific (or best) routes only on port15 and port16:

```
FGT_A (root) # get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 172.16.200.2, port1
          [1/0] via 172.16.208.2, dmz
          [1/0] via 172.16.209.2, port15
          [1/0] via 172.16.210.2, port16
S       10.1.100.22/32 [10/0] via 172.16.209.2, port15
          [10/0] via 172.16.210.2, port16
```

Because tie-break is set to fib-best-match, the first configured member from port15 and port16 is selected to forward traffic to PC_2. For all other traffic, the first configured member from all four of the interfaces is selected to forward traffic.

3. On PC-1, generate traffic to PC-2:

```
ping 10.1.100.22
```

4. On FGT_A, sniff for traffic sent to PC_2:

```
# diagnose sniffer packet any 'host 10.1.100.22' 4
interfaces=[any]
filters=[host 10.1.100.22]
2.831299 port5 in 172.16.205.11 -> 10.1.100.22: icmp: echo request
2.831400 port15 out 172.16.205.11 -> 10.1.100.22: icmp: echo request
```

Traffic is leaving on port15, the first configured member from port15 and port16.

Override quality comparisons in SD-WAN longest match rule matching

In SD-WAN rules, the longest match routes will override the quality comparisons when all of the specific routes are out of SLA.

With this feature in an SD-WAN rule:

- **Lowest Cost (sla):** Even though all of the egress ports on specific routes (longest matched routes) are out of SLA, the SD-WAN rule still selects the first configured or lower-cost port from the egress ports to forward traffic.
- **Best Quality (priority):** Even though the egress ports on specific routes (longest matched routes) have worse quality than all other ports on less specific routes, the SD-WAN rule still selects the best quality port from the ports on specific routes to forward traffic.

This feature avoids a situation where, if the members on specific routes (longest matched routes) are out of SLA or have worse quality, the traffic might be forwarded to the wrong members in SLA (higher quality) on the default or aggregate routes.

Example

In this example, four SD-WAN members in two zones are configured. The remote PC (PC_2 - 10.1.100.22) is accessible on port15 and port16, even though there are valid routes for all of the SD-WAN members. A single SD-WAN service rule is configured that allows traffic to be balanced between all four of the members, but only chooses between port15 and port16 for the specific 10.1.100.22 address. If neither port15 nor port16 meet the SLAs, traffic will be forwarded on one of these interfaces, instead of on port1 or dmz.

A performance SLA health check is configured to monitor 10.1.100.2. An SD-WAN service rule in Lowest Cost (SLA) mode is configured to select the best interface to steer the traffic. In the rule, the method of selecting a member if more than one meets the SLA (*tie-break*) is configured to select members that meet the SLA and match the longest prefix in the routing table (*fib-best-match*). If there are multiple ECMP routes with the same destination, the FortiGate will take the longest (or best) match in the routing table, and choose from those interface members.

To configure the SD-WAN:

```
config system sdwan
  config zone
    edit "virtual-wan-link"
    next
    edit "z1"
    next
  end
  config members
    edit 1
      set interface "port1"
      set gateway 172.16.200.2
    next
    edit 2
      set interface "dmz"
      set gateway 172.16.208.2
    next
    edit 3
      set interface "port15"
      set zone "z1"
      set gateway 172.16.209.2
    next
    edit 4
      set interface "port16"
      set zone "z1"
      set gateway 172.16.210.2
    next
  end
  config health-check
    edit "1"
      set server "10.1.100.2"
      set members 0
      config sla
```

```

        edit 1
        next
    end
next
end
config service
    edit 1
        set name "1"
        set mode sla
        set dst "all"
        set src "172.16.205.0"
        config sla
            edit "1"
                set id 1
            next
        end
        set priority-members 1 2 3 4
        set tie-break fib-best-match
    next
end
end

```

To check the results:

1. The debug shows the SD-WAN service rule. Both port15 and port16 are up, but out of SLA:

```

FGT_A (root) # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Members(4):
  1: Seq_num(1 port1), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
  2: Seq_num(2 dmz), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
  3: Seq_num(3 port15), alive, sla(0x0), gid(0), cfg_order(2), cost(0), selected
  4: Seq_num(4 port16), alive, sla(0x0), gid(0), cfg_order(3), cost(0), selected
Src address(1):
  172.16.205.0-172.16.205.255

Dst address(1):
  0.0.0.0-255.255.255.255

```

2. The routing table shows that there are ECMP default routes on all of the members, and ECMP specific (or best) routes only on port15 and port16:

```

FGT_A (root) # get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 172.16.200.2, port1
          [1/0] via 172.16.208.2, dmz
          [1/0] via 172.16.209.2, port15
          [1/0] via 172.16.210.2, port16
S       10.1.100.22/32 [10/0] via 172.16.209.2, port15
          [10/0] via 172.16.210.2, port16

```

Because **tie-break** is set to **fib-best-match**, even though both port15 and port16 are out of SLA, the first configured member of the two (port15) is selected to forward traffic to PC_2. For all other traffic, the first configured member from all of the interfaces that are in SLA is selected to forward traffic (port1).

3. On PC-1, generate traffic to PC-2:

```
ping 10.1.100.22
```

4. On FGT_A, sniff for traffic sent to PC_2:

```
# diagnose sniffer packet any 'host 10.1.100.22' 4
interfaces=[any]
filters=[host 10.1.100.22]
2.831299 port5 in 172.16.205.11 -> 10.1.100.22: icmp: echo request
2.831400 port15 out 172.16.205.11 -> 10.1.100.22: icmp: echo request
```

Traffic is leaving on port15, the first configured member from port15 and port16, even though both are out of SLA.

Internet service and application control steering

An application, application group, or application category can be selected as an SD-WAN service rule destination criterion for IPv4 and IPv6 address modes.

To configure from the CLI:

```
config system sdwan
  config service
    edit <id>
      set internet-service enable
      set internet-service-app-ctrl <app id> [app id] // basically can be one or more app
IDs
      set internet-service-app-ctrl-group <app group> [app group]
      set internet-service-app-ctrl-category <category id> [category id]
    next
  end
end
```

To configure for IPv6 addressing mode from the CLI, enable `addr-mode ipv6`:

```
config system sdwan
  config service
    edit <id>
      set addr-mode ipv6
    next
  end
end
```

To view the detected application category details based on category ID, use `diagnose sys sdwan internet-service-app-ctrl-category-list <id>`.

This topic includes a GUI and CLI [Example for application category on page 829](#) and a CLI [Example for IPv6 on page 834](#).

Example for application category

In this example, traffic steering is applied to traffic detected as video/audio (category ID 5) or email (category ID 21) and applies the lowest cost (SLA) strategy to this traffic. When costs are tied, the priority goes to member 1, dmz.

To configure application categories as an SD-WAN rule destination in the GUI:

1. Enable the feature visibility:
 - a. Go to *System > Feature Visibility*.
 - b. In the *Additional Features* section, enable *Application Detection Based SD-WAN*.
 - c. Click *Apply*.

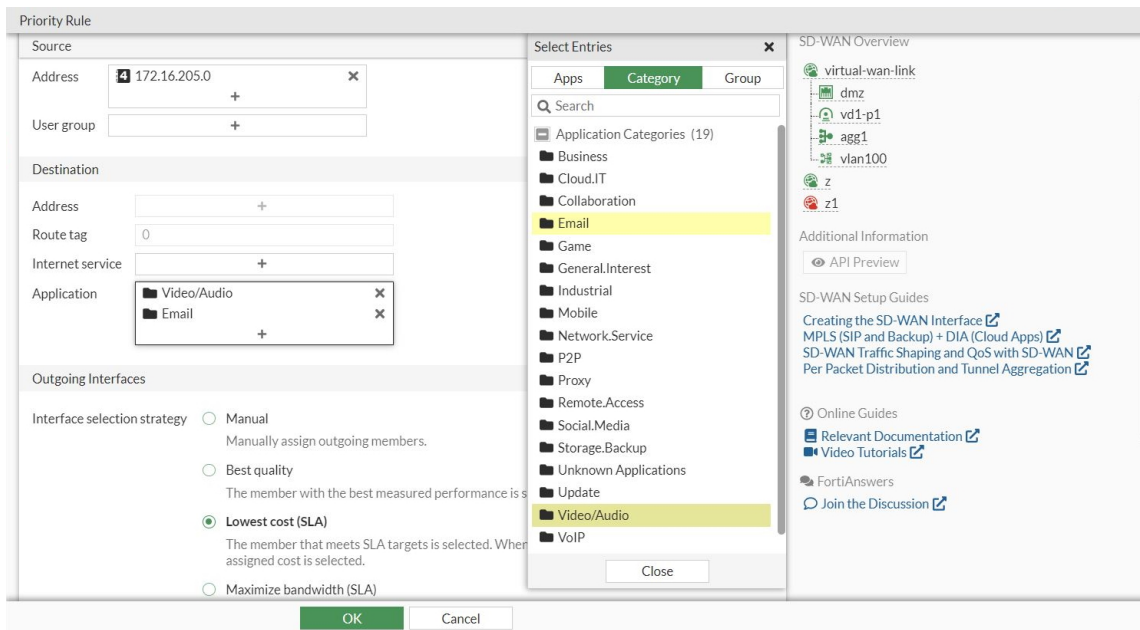

To enable GUI visibility of application detection based SD-WAN in the CLI:

```
config system global
    set gui-app-detection-sdwan enable
end
```

2. Configure the SD-WAN members:
 - a. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
 - b. Set the *Interface* to *dmz*, and set the *Gateway* to *172.16.208.2*.
 - c. Click *OK*.
 - d. Repeat these steps to create another member for the *vlan100* interface with gateway *172.16.206.2*.
3. Configure the performance SLA (health check):
 - a. Go to *Network > SD-WAN*, and select the *Performance SLAs* tab, and click *Create New*.
 - b. Configure the following settings:

Name	1
Protocol	DNS
Server	8.8.8.8
SLA Target	Enable

- c. Click *OK*.
4. Configure the SD-WAN rule to use the video/audio and email application categories:
 - a. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
 - b. In the *Destination* section, click the + in the *Application* field.
 - c. Click *Category*, and select *Video/Audio* and *Email*.

- d. Configure the other settings as needed.
- e. Click OK.
5. Configure the firewall policy:
 - a. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
 - b. Configure the following settings:

Incoming Interface	<i>port5</i>
Outgoing Interface	<i>virtual-wan-link</i>
Source	<i>172.16.205.0</i>
Destination	<i>all</i>
Schedule	<i>always</i>
Service	<i>ALL</i>
Action	<i>ACCEPT</i>
Application Control	<i>g-default</i>
SSL Inspection	<i>certificate-inspection</i>

- c. Click OK.

To configure application categories as an SD-WAN rule destination in the CLI:

1. Configure the SD-WAN settings:

```
config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
```

```

end
config members
    edit 1
        set interface "dmz"
        set gateway 172.16.208.2
    next
    edit 2
        set interface "vlan100"
        set gateway 172.16.206.2
    next
end
config health-check
    edit "1"
        set server "8.8.8.8"
        set protocol dns
        set members 0
        config sla
            edit 1
                next
            end
        next
    end
end
end

```

2. Configure the SD-WAN rule to use application categories 5 and 21:

```

config system sdwan
    config service
        edit 1
            set name "1"
            set mode sla
            set src "172.16.205.0"
            set internet-service enable
            set internet-service-app-ctrl-category 5 21
            config sla
                edit "1"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
end

```

3. Configure the firewall policy:

```

config firewall policy
    edit 1
        set srcintf "port5"
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr 172.16.205.0
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
    end
end

```

```

        set application-list "g-default"
    next
end

```

To test the configuration:

1. Verify that the traffic is sent over dmz:

```

# diagnose firewall proute list
list route policy info(vf=root):
id=2133590017(0x7f2c0001) vwl_service=1(1) vwl_mbr_seq=1 2 dscp_tag=0xff 0xff flags=0x0
tos=0x00 tos_mask=0x00 protocol=0 sport=0-65535 iif=0 dport=1-65535 path(2) oif=5(dmz)
oif=95(vlan100)
source(1): 172.16.205.0-172.16.205.255
destination wildcard(1): 0.0.0.0/0.0.0.0
internet service(2): (null)(0,5,0,0,0) (null)(0,21,0,0,0)
hit_count=469 last_used=2021-12-15 15:06:05

```

2. View some videos and emails on the PC, then verify the detected application details for each category:

```

# diagnose sys sdwan internet-service-app-ctrl-category-list 5
YouTube(31077 4294838537): 142.250.217.110 6 443 Wed Dec 15 15:39:50 2021
YouTube(31077 4294838537): 173.194.152.89 6 443 Wed Dec 15 15:37:20 2021
YouTube(31077 4294838537): 173.194.152.170 6 443 Wed Dec 15 15:37:37 2021
YouTube(31077 4294838537): 209.52.146.205 6 443 Wed Dec 15 15:37:19 2021

# diagnose sys sdwan internet-service-app-ctrl-category-list 21
Gmail(15817 4294836957): 172.217.14.197 6 443 Wed Dec 15 15:39:47 2021

```

3. Verify that the captured email traffic is sent over dmz:

```

# diagnose sniffer packet any 'host 172.217.14.197' 4
interfaces=[any]
filters=[host 172.217.14.197]
5.079814 dmz out 172.16.205.100.60592 -> 172.217.14.197.443: psh 2961561240 ack
2277134591

```

4. Edit the SD-WAN rule so that dmz has a higher cost and vlan100 is preferred.

5. Verify that the traffic is now sent over vlan100:

```

# diagnose firewall proute list
list route policy info(vf=root):
id=2134048769(0x7f330001) vwl_service=1(1) vwl_mbr_seq=2 1 dscp_tag=0xff 0xff flags=0x0
tos=0x00 tos_mask=0x00 protocol=0 sport=0-65535 iif=0 dport=1-65535 path(2) oif=95
(vlan100) oif=5(dmz)
source(1): 172.16.205.0-172.16.205.255
destination wildcard(1): 0.0.0.0/0.0.0.0
internet service(2): (null)(0,5,0,0,0) (null)(0,21,0,0,0)
hit_count=635 last_used=2021-12-15 15:55:43

# diagnose sniffer packet any 'host 172.217.14.197' 4
interfaces=[any]
filters=[host 172.217.14.197]
304.625168 vlan100 in 172.16.205.100.60592 -> 172.217.14.197.443: psh 2961572711 ack
2277139565

```

Example for IPv6

In this example, SD-WAN is configured to use an IPv6 service rule to steer traffic from FGT_A to FGT_B based on the following application control options:

- Application Telnet
- An application group for ping
- An application category that includes SSH

When the rule is matched, traffic is steered based on the lowest cost SLA strategy. In this example, vlan100 is the preferred interface, and traffic is routed to vlan100 on FGT_B.

To view the configuration:

1. View the SD-WAN configuration on FGT_A:

SD-WAN has four members in the default virtual-wan-link zone, each with an IPv4 and IPv6 gateway. The SD-WAN service rule includes `internet-service-app-ctrl 16091` for the Telnet, `internet-service-app-ctrl-group "network-Ping"` for ping, and `internet-service-app-ctrl-category 15` for SSH applications.

```
(sdwan) # show
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
            next
        end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
            set gateway6 2000:172:16:208::2
        next
        edit 2
            set interface "IPSec-1"
        next
        edit 3
            set interface "aggl"
            set gateway 172.16.203.2
            set gateway6 2000:172:16:203::2
        next
        edit 4
            set interface "vlan100"
            set gateway 172.16.206.2
            set gateway6 2000:172:16:206::2
        next
    end
    config health-check
        edit "1"
            set addr-mode ipv6
            set server "2000::2:2:2:2"
            set members 0
            config sla
                edit 1
                    next
            end
        end
    end
```

```

        next
    end
    config service
        edit 1
            set name "1"
            set addr-mode ipv6
            set mode sla
            set internet-service enable
            set internet-service-app-ctrl 16091
            set internet-service-app-ctrl-group "network-Ping"
            set internet-service-app-ctrl-category 15
            config sla
                edit "1"
                    set id 1
                next
            end
            set priority-members 4 1 2 3
        next
    end
end

```

2. View the default route for FGT_A:

```

config router static
    edit 5
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
end

```

3. View the firewall policy for FGT_A:

The `utm-status` option is enabled to learn application 3T (3 tuple) information, and the default application profile of `g-default` is selected.

```

config firewall policy
    edit 1
        set uuid f09bddc4-def3-51ed-8517-0d8b6bc18f35
        set srcintf "any"
        set dstintf "any"
        set action accept
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "g-default"
    next
end

```

To verify the configuration:

1. On FGT_A, check the routing table:

The routing table has ECMP applied to default gateways for each SD-WAN member.

```

# get router info routing-table static
Routing table for VRF=0

```

```
S*      0.0.0.0/0 [1/0] via 172.16.203.2, agg1, [1/0]
        [1/0] via 172.16.206.2, vlan100, [1/0]
        [1/0] via 172.16.208.2, dmz, [1/0]
        [1/0] via IPSec-1 tunnel 172.16.209.2, [1/0]
```

2. Check the SD-WAN service:

Based on the service rule, member 4 named vlan100 is preferred. Traffic must also match the highlighted internet services.

```
# diagnose system sdwan service
```

```
Service(1): Address Mode(IPV6) flags=0x4200 use-shortcut-sla use-shortcut
Tie break: cfg

3. Initiate traffic for ping, Telnet, and SSH to FGT_B, then FGT_A will learn 3T information for these applications, and use the SD-WAN rule to route traffic for the applications to the preferred interface of vlan100.

- Following is the sniffer traffic for ping application. The ping traffic flows out of DMZ before 3T information is recognized, then out from vlan100 after T3 traffic is recognized:

```
# diagnose sniffer packet any 'host 2000::2:0:0:4' 4
interfaces=[any]
filters=[host 2000::2:0:0:4]

4. View the IPv6 application control internet service ID list:

```
# diagnose system sdwan internet-service-app-ctrl6-list
```

```
Telnet(16091 4294837974): 2000::2:0:0:4 6 23 Thu Apr 20 17:43:00 2023
IPv6.ICMP(16321 4294837087): 2000::2:0:0:4 58 0 Thu Apr 20 17:43:00 2023
```

5. View the IPv6 application control internet service ID list by category:

```
# diagnose system sdwan internet-service-app-ctrl6-category-list
```

```
SSH(16060 4294837772): 2000::2:0:0:4 6 22 Thu Apr 20 17:43:00 2023
```

Use maximize bandwidth to load balance traffic between ADVPN shortcuts

When ADVPN is configured on a FortiGate spoke along with an SD-WAN rule set to *Maximize Bandwidth SLA* (GUI) or load balance mode (CLI) as well as `tie-break` set to `fib-best-match`, then spoke-to-spoke traffic is load balanced between multiple ADVPN shortcuts when the shortcuts are within the configured SLA conditions.

Following is an example configuration with `set mode load-balance` and `set tie-break fib-best-match` enabled:

```
config system sdwan
  config service
    edit 3
      set mode load-balance
      set dst "all"
      config sla
        edit "ping"
          set id 1
        next
      end
      set priority-members 1 2
      set tie-break fib-best-match
    next
  end
end
```

Example

In this example SD-WAN is configured between one hub and multiple spokes, and the SD-WAN configuration shows SD-WAN rule 3 with the following required settings to enable spoke-to-spoke traffic between multiple ADVPN shortcuts:

- **set mode load-balance**
- **set tie-break fib-best-match**

```
show system sdwan
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "zon2"
        next
    end
    config members
        edit 1
            set interface "vd2-1"
            set cost 10
        next
        edit 2
            set interface "vd2-2"
            set cost 20
        next
    end
    config health-check
        edit "ping"
            set server "11.11.11.11"
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 200
                    set jitter-threshold 50
                next
                edit 2
                next
            end
        next
        edit "1"
        next
    end
    config service
        edit 1
            set dst "033"
            set priority-members 1
        next
        edit 2
            set dst "133"
            set priority-members 2
        next
        edit 3
            set mode load-balance
            set dst "all"
            config sla
                edit "ping"
                    set id 1
                next
```

```

        end
        set priority-members 1 2
        set tie-break fib-best-match
    next
end
end

```

To trigger spoke-to-spoke communication, run an ICMP ping on PC A with IP address 22.1.1.22 behind spoke 1 that is destined for PC B with IP address 33.1.1.33 behind spoke 2. The spoke-to-spoke traffic will be used to demonstrate load balancing between shortcuts in the CLI output of this topic.

To verify the configuration:

1. Confirm the ADVPN shortcuts are within the SLA conditions:

```

# diagnose system sdwan health-check
Health Check(ping):
Seq(1 vd2-1): state(alive), packet-loss(0.000%) latency(0.029), jitter(0.002), mos
(4.404), bandwidth-up(1999), bandwidth-dw(0), bandwidth-bi(1999) sla_map=0x3
Seq(1 vd2-1_0): state(alive), packet-loss(0.000%) latency(0.026), jitter(0.001), mos
(4.404), bandwidth-up(2000), bandwidth-dw(0), bandwidth-bi(2000) sla_map=0x3
Seq(2 vd2-2): state(alive), packet-loss(0.000%) latency(0.055), jitter(0.064), mos
(4.404), bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x3
Seq(2 vd2-2_0): state(alive), packet-loss(0.000%) latency(0.060), jitter(0.058), mos
(4.404), bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x3

```

2. Confirm the settings for SD-WAN rule 3:

```

# diagnose system sdwan service 3

Service(3): Address Mode(IPV4) flags=0x4200 use-shortcut-sla use-shortcut
Tie break: fib
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance hash-mode=round-robin)
Member sub interface(4):
    1: seq_num(1), interface(vd2-1):
        1: vd2-1_0(125)
    3: seq_num(2), interface(vd2-2):
        1: vd2-2_0(127)
Members(4):
    1: Seq_num(1 vd2-1), alive, sla(0x1), gid(2), num of pass(1), selected
    2: Seq_num(1 vd2-1_0), alive, sla(0x1), gid(2), num of pass(1), selected
    3: Seq_num(2 vd2-2), alive, sla(0x1), gid(2), num of pass(1), selected
    4: Seq_num(2 vd2-2_0), alive, sla(0x1), gid(2), num of pass(1), selected
Dst address(1):
    0.0.0.0-255.255.255.255

```

3. Confirm firewall policing routing list:

```

# diagnose firewall proute list 2131230723
list route policy info(vf=vd2):

id=2131230723(0x7f080003) vwl_service=3 vwl_mbr_seq=1 1 2 2 dscp_tag=0xfc 0xfc
flags=0x90 load-balance hash-mode=round-robin fib-best-match tos=0x00 tos_mask=0x00
protocol=0 sport=0-65535 iif=0(any) dport=1-65535 path(4) oif=116(vd2-1) num_pass=1
oif=125(vd2-1_0) num_pass=1 oif=117(vd2-2) num_pass=1 oif=127(vd2-2_0) num_pass=1
destination(1): 0.0.0.0-255.255.255.255
source wildcard(1): 0.0.0.0/0.0.0.0
hit_count=117 last_used=2023-04-21 15:49:59

```

4. Confirm the routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B*      0.0.0.0/0 [200/0] via 10.10.100.254 (recursive via vd2-1 tunnel 11.1.1.11),
01:26:14, [1/0]
                [200/0] via 10.10.200.254 (recursive via vd2-2 tunnel 11.1.2.11),
01:26:14, [1/0]
B      1.1.1.1/32 [200/0] via 11.1.1.1 [2] (recursive via 12.1.1.1, vd2-vlan12),
01:26:14, [1/0]
B      11.11.11.11/32 [200/0] via 10.10.100.254 (recursive via vd2-1 tunnel 11.1.1.11),
01:26:14, [1/0]
                [200/0] via 10.10.200.254 (recursive via vd2-2 tunnel 11.1.2.11),
01:26:14, [1/0]
B      33.1.1.0/24 [200/0] via 10.10.100.3 [2] (recursive is directly connected, vd2-1_
0), 01:19:41, [1/0]
                [200/0] via 10.10.200.3 [2] (recursive is directly connected, vd2-2_
0), 01:19:41, [1/0]
B      100.1.1.0/24 [200/0] via 10.10.100.254 (recursive via vd2-1 tunnel 11.1.1.11),
01:26:14, [1/0]
                [200/0] via 10.10.200.254 (recursive via vd2-2 tunnel 11.1.2.11),
01:26:14, [1/0]
```

5. Check the packet sniffer output for the default setting.

This step demonstrates routing for the default setting of `set tie-break zone`. The following packet sniffer output of ICMP pings demonstrates how spoke-to-spoke traffic (ping from 22.1.1.22 to 33.1.1.13) is load balanced between all parent tunnels and shortcuts, and is not limited to shortcuts within SLA.

```
# diagnose sniffer packet any "host 33.1.1.13" 4
interfaces=[any]
filters=[host 33.1.1.13]
14.665232 vd22-vlan22 out 22.1.1.22 -> 33.1.1.13: icmp: echo request
14.665234 npu0_vlink1 out 22.1.1.22 -> 33.1.1.13: icmp: echo request
14.665240 vd2-vlan22 in 22.1.1.22 -> 33.1.1.13: icmp: echo request

7. Check SD-WAN health.

When an ADVPN shortcut is out of SLA, traffic does not run on it. Shortcut vd2-1_0 is out of SLA.

```

# diagnose system sdwan health-check
Health Check(ping):
Seq(1 vd2-1): state(alive), packet-loss(6.000%) latency(0.026), jitter(0.001), mos
(4.401), bandwidth-up(1999), bandwidth-dw(0), bandwidth-bi(1999) sla_map=0x0
Seq(1 vd2-1_0): state(alive), packet-loss(18.182%) latency(0.033), jitter(0.003), mos
(4.395), bandwidth-up(2000), bandwidth-dw(0), bandwidth-bi(2000) sla_map=0x0
Seq(2 vd2-2): state(alive), packet-loss(0.000%) latency(0.024), jitter(0.001), mos
(4.404), bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x3
Seq(2 vd2-2_0): state(alive), packet-loss(0.000%) latency(0.033), jitter(0.005), mos
(4.404), bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x3

```

8. Check the sniffer packet:

No traffic runs on Shortcut vd2-1_0 because it is out of SLA.

```

# diagnose sniffer packet any "host 33.1.1.13" 4
interfaces=[any]
filters=[host 33.1.1.13]

```

Use SD-WAN rules to steer multicast traffic

SD-WAN rules can now steer multicast traffic. When an SD-WAN member is out of SLA, multicast traffic can fail over to another SD-WAN member, and switch back when SLA recovers.

The new `pim-use-sdwan` option enables or disables the use of SD-WAN for PIM (Protocol Independent Multicast) when checking RP (Rendezvous Point) neighbors and sending packets.

```

config router multicast
    config pim-sm-global
        set pim-use-sdwan {enable | disable}
    end
end

```

When SD-WAN steers multicast traffic, ADVPN is not supported. Use the `set shortcut` option to disable shortcuts for the service:

```

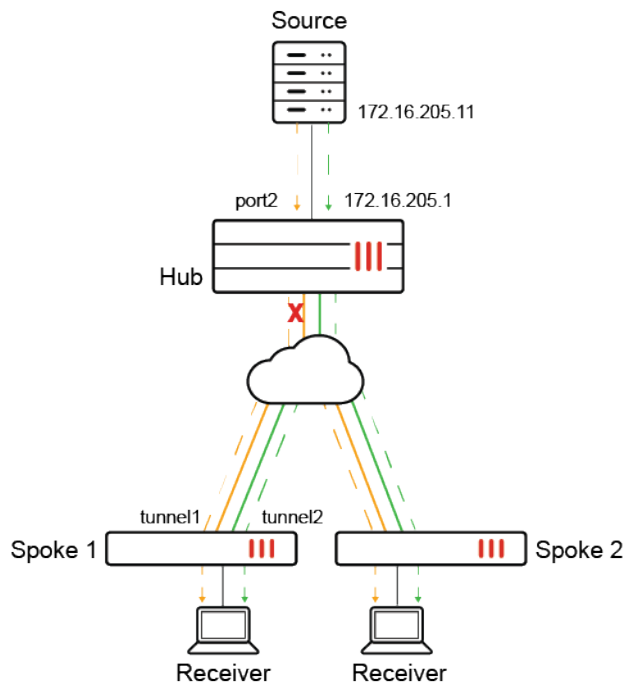

config system sdwan
    config service
        edit <id>
            set shortcut {enable | disable}
        next
    end
end

```

Example 1

In this hub and spoke example, the PIM source is behind the hub FortiGate, and the RP is set to internal port (port2) of the hub firewall. Each spoke connects to the two WAN interfaces on the hub by using an overlay tunnel. The overlay tunnels are members of SD-WAN.

Receivers behind the spoke FortiGates request a stream from the source to receive traffic on tunnel1 by default. When the overlay tunnel goes out of SLA, the multicast traffic fails over to tunnel2 and continues to flow.

Following is an overview of how to configure the topology:

1. Configure the hub FortiGate in front of the PIM source. The RP is configured on internal port (port2) of the hub FortiGate.
2. Configure the spoke FortiGates.
3. Verify traffic failover.

To configure the hub:

1. On the hub, enable multicast routing, configure the multicast RP, and enable PIM sparse mode on each interface:

```
config router multicast
    set multicast-routing enable
    config pim-sm-global
        config rp-address
            edit 1
                set ip-address 172.16.205.1
            next
        end
    end
    config interface
        edit "tport1"
            set pim-mode sparse-mode
        next
        edit "tagg1"
            set pim-mode sparse-mode
        next
        edit "port2"
            set pim-mode sparse-mode
        next
    end
end
```

To configure each spoke:

1. Enable SD-WAN with the following settings:
 - Configure the overlay tunnels as member of the SD-WAN zone.
 - Configure a performance SLA health-check using ping.
 - Configure a service rule for the PIM protocol with the following settings:
 - Use the lowest cost (SLA) strategy.
 - Monitor with the ping health-check.
 - Disable ADVPN shortcut.

```

config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
  end
  config members
    edit 1
      set interface "tunnel1"
    next
    edit 2
      set interface "tunnel2"
    next
  end
  config health-check
    edit "ping"
      set server "172.16.205.1"
      set update-static-route disable
      set members 0
      config sla
        edit 1
        next
      end
    next
  end
  config service
    edit 1
      set mode sla
      set protocol 103
      set dst "all"
      config sla
        edit "ping"
          set id 1
        next
      end
      set priority-members 1 2
      set use-shortcut-sla disable
      set shortcut disable
    next
    edit 2
      set mode sla
      set dst "all"
      config sla
        edit "ping"
          set id 1

```

```

        next
    end
    set priority-members 1 2
next
end
end

```

2. Enable multicast routing and configure the multicast RP. Enable PIM sparse-mode on each interface:

```

config router multicast
    set multicast-routing enable
    config pim-sm-global
        set spt-threshold disable
        set pim-use-sdwan enable
    config rp-address
        edit 1
            set ip-address 172.16.205.1
        next
    end
end
config interface
    edit "tunnel1"
        set pim-mode sparse-mode
    next
    edit "tunnel2"
        set pim-mode sparse-mode
    next
    edit "port4"
        set pim-mode sparse-mode
    next
end
end

```

To verify traffic failover:

With this configuration, multicast traffic starts on tunnel1. When tunnel1 becomes out of SLA, traffic switches to tunnel2. When tunnel1 is in SLA again, the traffic switches back to tunnel1.

The following health-check capture on the spokes shows tunnel1 in SLA with packet-loss (1.000%):

```

# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel1): state(alive), packet-loss(0.000%) latency(0.056), jitter(0.002), mos(4.404),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x1
Seq(2 tunnel2): state(alive), packet-loss(0.000%) latency(0.100), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1

# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel1): state(alive), packet-loss(1.000%) latency(0.056), jitter(0.002), mos(4.404),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x1
Seq(2 tunnel2): state(alive), packet-loss(0.000%) latency(0.100), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1

```

The following example shows tunnel1 out of SLA with packet-loss (3.000%):

```

# diagnose sys sdwan health-check
Health Check(ping):

```

```
Seq(1 tunnel1): state(alive), packet-loss(3.000%) latency(0.057), jitter(0.003), mos(4.403),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x0
Seq(2 tunnel2): state(alive), packet-loss(0.000%) latency(0.101), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1
```

The following example shows tunnel1 back in SLA again:

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel1): state(alive), packet-loss(1.000%) latency(0.061), jitter(0.004), mos(4.404),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x0
Seq(2 tunnel2): state(alive), packet-loss(0.000%) latency(0.102), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1

# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel1): state(alive), packet-loss(0.000%) latency(0.061), jitter(0.004), mos(4.404),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x0
Seq(2 tunnel2): state(alive), packet-loss(0.000%) latency(0.102), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1
```

The following example how traffic switches to tunnel2 while tunnel1 health-check is out of SLA. Source (172.16.205.11) sends traffic to the multicast group. Later the traffic switches back to tunnel1 once SLA returns to normal:

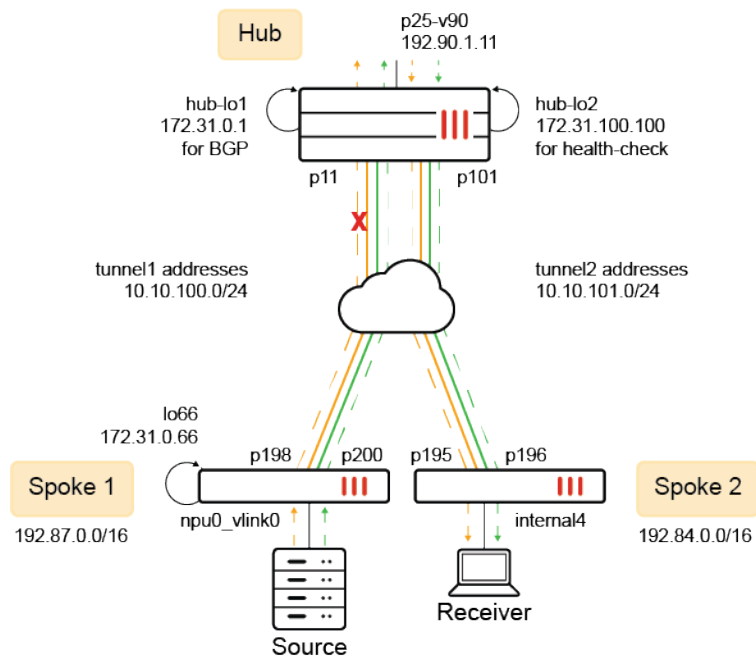

```
195.060797 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
195.060805 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
196.060744 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
196.060752 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
197.060728 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
197.060740 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
198.060720 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
198.060736 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
199.060647 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
199.060655 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
200.060598 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
200.060604 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
... ..
... ..
264.060974 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
265.060950 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
265.060958 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
266.060867 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
266.060877 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
267.060828 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
267.060835 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
268.060836 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
268.060854 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
269.060757 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
269.060767 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
270.060645 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
270.060653 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
```

Example 2

In this hub and spoke example, the PIM source is behind spoke 1, and the RP is configured on the hub FortiGate. BGP is used for routing. The hub uses embedded SLA in ICMP probes to determine the health of each tunnel, allowing it to prioritize healthy IKE routes.

The receiver is on another spoke. Upon requesting a stream, source passes the traffic to the RP on the hub FortiGate, and routes the traffic to the receiver over tunnel1. If a tunnel falls out of SLA, the multicast traffic fails over to the other tunnel.

In this configuration, SD-WAN steers multicast traffic by using embedded SLA information in ICMP probes. See also [Embedded SD-WAN SLA information in ICMP probes](#). With this feature, the hub FortiGate can use the SLA information of the spoke's health-check to control BGP and IKE routes over tunnels.

Following is an overview of how to configure the topology:

1. Configure the hub FortiGate. The RP is configured on the hub FortiGate.
2. Configure the spoke FortiGate in front of the traffic receiver.
3. Configure the spoke FortiGate in front of the PIM source.

To configure the hub:

1. Configure loopbacks hub-lo1 172.31.0.1 for BGP and hub-lo100 172.31.100.100 for health-check:

```
config system interface
  edit "hub-lo1"
    set vdom "hub"
    set ip 172.31.0.1 255.255.255.255
    set allowaccess ping
    set type loopback
    set snmp-index 82
  next
  edit "hub-lo100"
```

```

        set vdom "hub"
        set ip 172.31.100.100 255.255.255.255
        set allowaccess ping
        set type loopback
        set snmp-index 81
    next
end

```

2. Enable multicast routing with the following settings:

- Configure internal interface p25-v90 as RP.
- Enable interfaces for PIM sparse-mode.

```

config router multicast
    set multicast-routing enable
    config pim-sm-global
        config rp-address
            edit 1
                set ip-address 192.90.1.11
            next
        end
    end
end
config interface
    edit "p11"
        set pim-mode sparse-mode
    next
    edit "p101"
        set pim-mode sparse-mode
    next
    edit "p25-v90"
        set pim-mode sparse-mode
    next
end
end

```

3. Enable SD-WAN with the following settings:

- Add interfaces p11 and p101 as members.
- Configure embedded SLA health-checks to detect ICMP probes from each overlay tunnel. Prioritize based on the health of each tunnel.

```

config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "p11"
        next
        edit 2
            set interface "p101"
        next
    end
    config health-check
        edit "1"
            set detect-mode remote

```

```

        set probe-timeout 60000
        set recoverytime 1
        set sla-id-redistribute 1
        set members 1
        config sla
            edit 1
                set link-cost-factor latency
                set latency-threshold 100
                set priority-in-sla 10
                set priority-out-sla 20
            next
        end
    next
    edit "2"
        set detect-mode remote
        set probe-timeout 60000
        set recoverytime 1
        set sla-id-redistribute 1
        set members 2
        config sla
            edit 1
                set link-cost-factor latency
                set latency-threshold 100
                set priority-in-sla 15
                set priority-out-sla 25
            next
        end
    next
end
end
end

```

4. Configure BGP to peer with neighbors. Neighbor group is configured for tunnel interface IP addresses:

```

config router bgp
    set as 65505
    set router-id 172.31.0.1
    set ibgp-multipath enable
    set additional-path enable
    set recursive-inherit-priority enable
    config neighbor-group
        edit "gr1"
            set remote-as 65505
            set update-source "hub-lol"
            set additional-path both
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 10.10.0.0 255.255.0.0
            set neighbor-group "gr1"
        next
    edit 66

```

```

        set prefix 172.31.0.66 255.255.255.255
        set neighbor-group "gr1"
    next
end
config network
    ....
    edit 90
        set prefix 192.90.0.0 255.255.0.0
    next
end
end

```

To configure the spoke (in front of the receiver):

1. Enable multicast routing to use SD-WAN. Configure the RP address. Enable interfaces for PIM sparse-mode.

```

config router multicast
    set multicast-routing enable
    config pim-sm-global
        set spt-threshold disable
        set pim-use-sdwan enable
    config rp-address
        edit 1
            set ip-address 192.90.1.11
        next
    end
end
config interface
    edit "p195"
        set pim-mode sparse-mode
    next
    edit "p196"
        set pim-mode sparse-mode
    next
    edit "internal4"
        set pim-mode sparse-mode
        set static-group "225-1-1-122"
    next
end
end

```

2. Configure SD-WAN with the following settings:

- Add overlay tunnel interfaces as members.
- Configure a performance SLA health-check to send ping probes to the hub.
- Configure a service rule for the PIM protocol. Use the lowest cost (SLA) strategy, and monitor with the ping health-check.
- Disable ADVPN shortcuts.

```

config system sdwan
    set status enable

```

```
config zone
    edit "virtual-wan-link"
    next
end
config members
    edit 6
        set interface "p196"
    next
    edit 5
        set interface "p195"
    next
end
config health-check
    edit "ping"
        set server "172.31.100.100"
        set update-static-route disable
        set members 0
        config sla
            edit 1
                set link-cost-factor latency
                set latency-threshold 100
            next
        end
    next
end
config service
    edit 1
        set mode sla
        set protocol 103
        set dst "all"
        config sla
            edit "ping"
                set id 1
            next
        end
        set priority-members 5 6
        set use-shortcut-sla disable
        set shortcut disable
    next
    edit 2
        set mode sla
        set dst "all"
        config sla
            edit "ping"
                set id 1
            next
        end
        set priority-members 5 6
```

```
        next
    end
end
```

3. Configure BGP and set neighbors to the overlay gateway IP address on the hub:

```
config router bgp
    set as 65505
    set router-id 122.1.1.122
    set ibgp-multipath enable
    set additional-path enable
    config neighbor
        edit "10.10.100.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set connect-timer 10
            set additional-path both
        next
        edit "10.10.101.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set connect-timer 10
            set additional-path both
        next
    end
    config network
        edit 3
            set prefix 192.84.0.0 255.255.0.0
        next
    end
end
```

4. Configure the default gateway to use the SD-WAN zone. Other routes are for the underlay to route traffic to the hub's WAN interfaces:

```
config router static
    edit 10
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
    ....
    next
end
```

To configure the spoke (in front of the source):

1. Enable multicast routing to use SD-WAN. Configure the RP address. Enable interfaces for PIM sparse-mode:

```
config router multicast
    set multicast-routing enable
    config pim-sm-global
        set pim-use-sdwan enable
    config rp-address
```

```

        edit 1
            set ip-address 192.90.1.11
        next
    end
end
config interface
    edit "p198"
        set pim-mode sparse-mode
    next
    edit "p200"
        set pim-mode sparse-mode
    next
    edit "np0_vlink0"
        set pim-mode sparse-mode
    next
end
end

```

2. Configure loopback interface lo66 for BGP and sourcing SD-WAN traffic:

```

config system interface
    edit "lo66"
        set vdom "root"
        set ip 172.31.0.66 255.255.255.255
        set allowaccess ping
        set type loopback
        set snmp-index 21
    next
end

```

3. Configure SD-WAN:

- Add overlay tunnel interfaces as members.
- Configure a performance SLA health-check to send ping probes to the hub.
- Configure a service rule for the PIM protocol. Use the lowest cost (SLA) strategy, and monitor with the ping health-check.
- Disable the use of an ADVPN shortcut.

In the following example, 11.11.11.11 is the underlay address for one of the WAN links on the hub, and 172.31.100.100 is the loopback address on the server.

```

config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "overlay"
        next
    end
    config members
        edit 1
            set interface "p198"
            set zone "overlay"
            set source 172.31.0.66
        next
        edit 2
            set interface "p200"
            set zone "overlay"
        next
    end
end

```

```

        set source 172.31.0.66
    next
end
config health-check
    edit "ping"
        set server "11.11.11.11"
        set members 0
        config sla
            edit 1
                set link-cost-factor latency
                set latency-threshold 100
            next
        end
    next
    edit "HUB"
        set server "172.31.100.100"
        set embed-measured-health enable
        set members 0
        config sla
            edit 1
                set link-cost-factor latency
                set latency-threshold 100
            next
        end
    next
end
config service
    edit 1
        set mode sla
        set protocol 103
        set dst "all"
        config sla
            edit "ping"
                set id 1
            next
        end
        set priority-members 1 2
        set use-shortcut-sla disable
        set shortcut disable
    next
    edit 2
        set mode sla
        set dst "all"
        config sla
            edit "ping"
                set id 1
            next
        end
        set priority-members 1 2
    next
end
end

```

4. Configure BGP:

```

config router bgp
    set as 65505

```

```

set router-id 123.1.1.123
set ibgp-multipath enable
set additional-path enable
config neighbor
    edit "172.31.0.1"
        set next-hop-self enable
        set soft-reconfiguration enable
        set remote-as 65505
        set update-source "lo66"
    next
end
config network
    edit 3
        set prefix 192.87.0.0 255.255.0.0
    next
end
end

```

5. Configure the default gateway to use the SD-WAN zone. Other routes are for the underlay to route to the hub's WAN interfaces:

```

config router static
    edit 10
        set distance 1
        set sdwan-zone "virtual-wan-link" "overlay"
    next
    ...
    next
end

```

Advanced routing

The following topics provide instructions on SD-WAN advanced routing:

- [Local out traffic on page 858](#)
- [Using BGP tags with SD-WAN rules on page 864](#)
- [BGP multiple path support on page 868](#)
- [Controlling traffic with BGP route mapping and service rules on page 870](#)
- [Applying BGP route-map to multiple BGP neighbors on page 877](#)
- [Using multiple members per SD-WAN neighbor configuration on page 883](#)

Local out traffic

Local out, or self-originating, traffic is traffic that originates from the FortiGate going to external servers and services. The traffic can be from Syslog, FortiAnalyzer logging, FortiGuard services, remote authentication, and others.

By default, local out traffic relies on routing table lookups to determine the egress interface that is used to initiate the connection. However, many types of local out traffic support selecting the egress interface based on SD-WAN or manually specified interfaces. When manually specifying the egress interface, the source IP address can also be manually configured.

Go to *Network > Local Out Routing* to configure the available types of local out traffic. Some types of traffic can only be configured in the CLI.

By default *Local Out Routing* is not visible in the GUI. Go to *System > Feature Visibility* to enable it. See [Feature visibility on page 2702](#) for more information.

When VDOMs are enabled, the following entries are available on the local out routing page:

Global view	VDOM view
External Resources	LDAP Servers
AWS_IP_Blacklist	ldap
AWS_Malware_Hash	
Log	Log
Log FortiAnalyzer Setting	Log FortiAnalyzer Override Settings
Log FortiAnalyzer Cloud Setting	Log Syslogd Override Settings
FortiGate Cloud Log Settings	
Log Syslogd Setting	RADIUS Servers
	fac_radius_server
System	TACACS+
System DNS	TACACS
System FortiGuard	
System FortiSandbox	

If a service is disabled, it is grayed out. To enable it, select the service and click *Enable Service*. If a service is enabled, there is a *Local Out Setting* button in the gutter of that service's edit page to directly configure the local-out settings.

Examples

To configure DNS local-out routing:

1. Go to *Network > Local Out Routing* and double-click *System DNS*.
2. For *Outgoing interface*, select one of the following:

Auto	Select the outgoing interface automatically based on the routing table.
SD-WAN	Select the outgoing interface using the configured SD-WAN interfaces and rules.
Specify	Select the outgoing interface from the dropdown.
3. Use Interface IP	Use the primary IP, which cannot be configured by the user.

Manually

Selected an IP from the list, if the selected interface has multiple IPs configured.

If *Specify* is selected, select a setting for *Source IP*:

4. Click **OK**.

To edit local-out settings from a **RADIUS** server entry:

1. Go to *User & Authentication > RADIUS Servers* and double-click an entry to edit it.
2. Click *Local Out Setting*.

The *Edit Local Out Setting* pane opens.

3. Configure the settings for *Outgoing interface* and *Source IP*.

4. Click **OK**.

To edit multiple entries concurrently:

1. Go to *Network > Local Out Routing*.
2. If applicable, select *IPv4* or *IPv6*. *IPv4+IPv6* does not support multi-select.
3. Click *Multi-Select Mode*. All of the local out settings that can be edited concurrently are shown.
4. Select the specific entries, or click *Select All* to select all of the entries.

Enable Service	Edit	Exit Multi-Select Mode	Select All	Search
	Name	Source IP	Outgoing Interface	IP Version
Log	FortiGate Cloud Log Settings	Dynamic	Auto	IPv4
System	System DNS	Dynamic	Auto	IPv4
	System FortiGuard	Dynamic	Auto	IPv4

5. Click **Edit** and configure the local out settings as required.

6. Click **OK**.
7. Click *Exit Multi-Select Mode* to return to the normal view.

Configuring local out routing in the CLI

Some local out routing settings can only be configured using the CLI.

PING

IPv4 and IPv6 pings can be configured to use SD-WAN rules:

```
execute ping-options use-sdwan {yes | no}
execute ping6-options use-sdwan {yes | no}
```

Traceroute

IPv4 traceroute can be configured to use SD-WAN rules:

```
execute traceroute-options use-sdwan {yes | no}
```

Central management

Central management traffic can use SD-WAN rules or a specific interface:

```
config system central-management
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

NTP server

NTP server traffic can use SD-WAN rules or a specific interface:

```
config system ntp
    config ntpserver
        edit <id>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        next
    end
end
```

DHCP proxy

DHCP proxy traffic can use SD-WAN rules or a specific interface:

```
config system settings
    set dhcp-proxy-interface-select-method {auto | sdwan | specify}
    set dhcp-proxy-interface <interface>
end
```

dhcp-proxy-interface-select-method {auto | sdwan | specify}

Select the interface selection method:

- **auto:** Set the outgoing interface automatically (default).
- **sdwan:** Set the interface by SD-WAN or policy routing rules.
- **specify:** Set the interface manually.

dhcp-proxy-interface <interface>

Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.

DHCP relay

DHCP relay traffic can use SD-WAN rules or a specific interface:

```
config system interface
    edit <interface>
        set dhcp-relay-interface-select-method {auto | sdwan | specify}
```

```

        set dhcp-relay-interface <interface>
    next
end

```

dhcp-relay-interface-select-method {auto | sdwan | specify}

Select the interface selection method:

- **auto:** Set the outgoing interface automatically (default).
- **sdwan:** Set the interface by SD-WAN or policy routing rules.
- **specify:** Set the interface manually.

dhcp-relay-interface <interface>

Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.

CA and local certificate renewal with SCEP

Certificate renewal with SCEP traffic can use SD-WAN rules or a specific interface:

```

config vpn certificate setting
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end

```

IPS TLS protocol active probing

TLS active probing can use SD-WAN rules or a specific interface:

```

config ips global
    config tls-active-probe
        set interface-selection-method {auto | sdwan | specify}
        set interface <interface>
        set vdom <VDOM>
        set source-ip <IPv4 address>
        set source-ip6 <IPv6 address>
    end
end

```

interface-select-method {auto | sdwan | specify}

Select the interface selection method:

- **auto:** Set the outgoing interface automatically (default).
- **sdwan:** Set the interface by SD-WAN or policy routing rules.
- **specify:** Set the interface manually.

interface <interface>

Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.

vdom <VDOM>

Specify the VDOM. This option is only available and must be configured when `interface-select-method` is `sdwan` or `specify`.

source-ip <IPv4 address>

Specify the source IPv4 address. This option is only available and must be configured when `interface-select-method` is `sdwan` or `specify`.

source-ip6 <IPv6 address>

Specify the source IPv6 address. This option is only available and must be configured when `interface-select-method` is `sdwan` or `specify`.

Netflow and sflow

Netflow and sflow can use SD-WAN rules or a specific interface:

```
config system {netflow | sflow | vdom-netflow | vdom-sflow}
  set interface-select-method {auto | sdwan | specify}
  set interface <interface>
end
```

interface-select-method {auto sdwan specify}	Select the interface selection method: <ul style="list-style-type: none"> • auto: Set the outgoing interface automatically (default). • sdwan: Set the interface by SD-WAN or policy routing rules. • specify: Set the interface manually.
interface <interface>	Specify the outgoing interface. This option is only available and must be configured when <code>interface-select-method</code> is <code>specify</code> .

FortiClient EMS

FortiClient EMS endpoint control traffic can use SD-WAN rules or a specific interface:

```
config endpoint-control fctems
  edit fctems1
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
  end
end
```

TACACS+

System log entries can be sent to external TACACS+ accounting servers. TACACS+ traffic can use SD-WAN rules or a specific IP address:

```
config log tacacs+accounting setting
  set interface-select-method {auto | sdwan | specify}
  set source-ip <IP address>
end
```

Using BGP tags with SD-WAN rules

SD-WAN rules can use Border Gateway Protocol (BGP) learned routes as dynamic destinations.

In this example, a customer has two ISP connections, wan1 and wan2. wan1 is used primarily for direct access to internet applications, and wan2 is used primarily for traffic to the customer's data center.

The customer could create an SD-WAN rule using the data center's IP address range as the destination to force that traffic to use wan2, but the data center's IP range is not static. Instead, a BGP tag can be used.

For this example, wan2's BGP neighbor advertises the data center's network range with a community number of 30:5.

This example assumes that SD-WAN is enabled on the FortiGate, wan1 and wan2 are added as SD-WAN members in the *virtual-wan-link* SD-WAN zone, and a policy and static route have been created. See [SD-WAN quick start on page 704](#) for details.

FortiOS supports IPv4 and IPv6 route tags.

To configure BGP tags with SD-WAN rules:

1. Configure the community list:

```
config router community-list
  edit "30:5"
    config rule
      edit 1
        set action permit
        set match "30:5"
      next
    end
  next
end
```

2. Configure the route map:

```
config router route-map
  edit "comm1"
    config rule
      edit 1
        set match-community "30:5"
        set set-route-tag 15
      next
    end
  next
end
```

3. Configure BGP:

```
config router bgp
  set as xxxxx
  set router-id xxxx
  config neighbor
    edit "10.100.20.2"
      set soft-reconfiguration enable
      set remote-as xxxxx
      set route-map-in "comm1"
    next
  end
end
```

4. Configure the route tag address object:

```
config firewall address
  edit "DataCenter_route_tag_15"
    set type route-tag
    set route-tag 15
```

```

    next
end

```

5. Configure a firewall policy:

```

config firewall policy
    edit 1
        set name "1"
        set srcintf "dmz"
        set dstintf "virtual-wan-link"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end

```

6. Edit the SD-WAN configuration:

```

config system sdwan
    set status enable
    config members
        edit 1
            set interface "wan1"
            set gateway 172.16.20.2
        next
        edit 2
            set interface "wan2"
        next
    end
    config service
        edit 1
            set name "DataCenter"
            set mode manual
            set priority-members 2
        next
    end
end

```

Troubleshooting BGP tags with SD-WAN rules

Check the network community

Use the `get router info bgp network` command to check the network community:

```

# get router info bgp network
BGP table version is 5, local router ID is 1.1.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network Next Hop Metric LocPrf Weight RouteTag Path
*> 0.0.0.0/0 10.100.1.5 32768 0 ?
*> 1.1.1.1/32 0.0.0.0 32768 0 ?
*> 10.1.100.0/24 172.16.203.2 32768 0 ?

```

```

*> 10.100.1.0/30 0.0.0.0 32768 0 ?

# get router info bgp network 10.100.11.0
BGP routing table entry for 10.100.10.0/24
Paths: (2 available, best 1, table Default-IP-Routing-Table)
  Advertised to non peer-group peers:
    172.10.22.2
  20
    10.100.20.2 from 10.100.20.2 (6.6.6.6)
      Origin EGP metric 200, localpref 100, weight 10000, valid, external, best
      Community: 30:5 <<<=====
      Last update: Wen Mar 20 18:45:17 2019

```

Check dynamic BGP addresses

Use the `get router info route-map-address` command to check dynamic BGP addresses:

```

# get router info route-map-address
Extend-tag: 15, interface(wan2:16)
  10.100.11.0/255.255.255.0

```

Check dynamic BGP addresses used in policy routes

Use the `diagnose firewall proute list` command to check dynamic BGP addresses used in policy routes:

```

# diagnose firewall proute list
list route policy info(vf=root):

```

```
id=4278779905 vwl_service=1(DataCenter) flags=0x0 tos=0x00 tos_mask=0x00 protocol=0
sport=0:65535 iif=0 dport=1-65535 oif=16
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 10.100.11.0/255.255.255.0
```

BGP multiple path support

BGP supports multiple paths, allowing an ADVPN to advertise multiple paths. This allows BGP to extend and keep additional network paths according to [RFC 7911](#).

In this example, Spoke1 and Spoke2 each have four VPN tunnels that are connected to the Hub with ADVPN. The Spoke-Hub has established four BGP neighbors on all four tunnels.

Spoke 1 and Spoke 2 can learn four different routes from each other.

To configure the hub:

```
config router bgp
  set as 65505
  set router-id 11.11.11.11
  set ibgp-multipath enable
  set additional-path enable
  set additional-path-select 4
  config neighbor-group
    edit "gr1"
      set capability-default-originate enable
      set remote-as 65505
      set additional-path both
      set adv-additional-path 4
      set route-reflector-client enable
    next
  end
  config neighbor-range
    edit 1
      set prefix 10.10.0.0 255.255.0.0
```

```
        set neighbor-group "gr1"
    next
end
config network
    edit 12
        set prefix 11.11.11.11 255.255.255.255
    next
end
end
```

To configure a spoke:

```
config router bgp
    set as 65505
    set router-id 2.2.2.2
    set ibgp-multipath enable
    set additional-path enable
    set additional-path-select 4
    config neighbor
        edit "10.10.100.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
        edit "10.10.200.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
        edit "10.10.203.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
        edit "10.10.204.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
    end
    config network
        edit 3
            set prefix 22.1.1.0 255.255.255.0
        next
    end
end
```

To view the BGP routing table on a spoke:

```
Spoke1 # get router info routing-table bgp
Routing table for VRF=0
B*      0.0.0.0/0 [200/0] via 10.10.200.254, vd2-2, 03:57:26
```

```

[200/0] via 10.10.203.254, vd2-3, 03:57:26
[200/0] via 10.10.204.254, vd2-4, 03:57:26
[200/0] via 10.10.100.254, vd2-1, 03:57:26
B      1.1.1.1/32 [200/0] via 11.1.1.1 (recursive via 12.1.1.1), 03:57:51
[200/0] via 11.1.1.1 (recursive via 12.1.1.1), 03:57:51
[200/0] via 11.1.1.1 (recursive via 12.1.1.1), 03:57:51
[200/0] via 11.1.1.1 (recursive via 12.1.1.1), 03:57:51
B      11.11.11.11/32 [200/0] via 10.10.200.254, vd2-2, 03:57:51

[200/0] via 10.10.100.3, vd2-1, 03:57:26

```

Controlling traffic with BGP route mapping and service rules

SD-WAN allows you to select different outbound WAN links based on performance SLAs. It is important that BGP neighbors are aware of these settings, and changes to them.

BGP can adapt to changes in SD-WAN link SLAs in the following ways:

- Applying different route-maps based on the SD-WAN's health checks. For example, different BGP community strings can be advertised to BGP neighbors when SLAs are not met.
- Traffic can be selectively forwarded based on the active BGP neighbor. If the SD-WAN service's role matches the active SD-WAN neighbor, the service is enabled. If there is no match, then the service is disabled.

Example

In this topology, a branch FortiGate has two SD-WAN gateways serving as the primary and secondary gateways. The gateways reside in different datacenters, but have a full mesh network between them.

This example shows how route-maps and service rules are selected based on performance SLAs and the member that is currently active. Traffic flows through the primary gateway unless the neighbor's health check is outside of its SLA. If that happens, traffic routes to the secondary gateway.

BGP NBR1 is the primary neighbor and BGP NBR2 is the secondary neighbor.

The branch FortiGate's wan1 and wan2 interfaces are members of the SD-WAN. When the SD-WAN neighbor status is primary, it will advertise community 20:1 to BGP NBR1 and 20:5 to BGP NBR2. When the SD-WAN neighbor status is secondary, it will advertise 20:5 to BGP NBR1 and 20:2 to BGP NBR2.

Only one of the primary or secondary neighbors can be active at one time. The SD-WAN neighbor status is used to decide which neighbor is selected:

- **Primary:** The primary neighbor takes precedence if its SLAs are met.
- **Secondary:** If the primary neighbor's SLAs are not met, the secondary neighbor becomes active if its SLAs are met.
- **Standalone:** If neither the primary or secondary neighbor's SLAs are met, the SD-WAN neighbor status becomes standalone.

Route map

SD-WAN is configured to let BGP advertise different communities when the SLA status changes. When the SLA is missed, it triggers BGP to advertise a different community to its BGP neighbor based on its route-map. The BGP neighbors can use the received community string to select the best path to reach the branch.

To configure BGP route-maps and neighbors:

1. Configure an access for the routes to be matched:

```
config router access-list
  edit "net192"
    config rule
      edit 1
        set prefix 192.168.20.0 255.255.255.0
      next
    end
```

```

    next
end

```

2. Configure the primary neighbor's preferred route-map:

```

config router route-map
    edit "comm1"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "20:1"
            next
        end
    next
end

```

3. Configure the secondary neighbor's preferred route-map:

```

config router route-map
    edit "comm2"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "20:2"
            next
        end
    next
end

```

4. Configure the failed route-map:

```

config router route-map
    edit "comm5"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "20:5"
            next
        end
    next
end

```

5. Configure BGP neighbors:

```

config router bgp
    set as 65412
    set router-id 1.1.1.1
    set ibgp-multipath enable
    config neighbor
        edit "10.100.1.1"
            set soft-reconfiguration enable
            set remote-as 20
            set route-map-out "comm5"
            set route-map-out-preferable "comm1"
        next
        edit "10.100.1.5"
            set soft-reconfiguration enable
            set remote-as 20
            set route-map-out "comm5"
        next
    end
end

```

```

        set route-map-out-preferable "comm2"
    next
end
end

```

When SLAs are met, `route-map-out-preferable` is used. When SLAs are missed, `route-map-out` is used.

To configure SD-WAN:

1. Configure the SD-WAN members:

```

config system sdwan
    set status enable
    config members
        edit 1
            set interface "port1"
        next
        edit 2
            set interface "port2"
        next
    end
end

```

2. Configure health checks for each member:

```

config system sdwan
    config health-check
        edit "ping"
            set server "10.100.2.22"
            set members 1
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 1
                next
            end
        next
        edit "ping2"
            set server "10.100.2.23"
            set members 2
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 1
                next
            end
        next
    end
end

```

3. Configure the SD-WAN neighbors and assign them a role and the health checks used to determine if the neighbor meets the SLA:

SD-WAN neighbors can only be configured in the CLI.

```

config system sdwan
    config neighbor
        edit "10.100.1.1"
            set member 1
        next
    end
end

```

```

        set role primary
        set health-check "ping"
        set sla-id 1
    next
    edit "10.100.1.5"
        set member 2
        set role secondary
        set health-check "ping2"
        set sla-id 1
    next
end
end

```

Service rules

Create SD-WAN service rules to direct traffic to the primary neighbor when its SLAs are met, and to the secondary neighbor when the primary neighbor's SLAs are missed.

To configure the SD-WAN service rules:

```

config system sdwan
config service
edit 1
    set name "Primary-Out"
    set role primary
    set dst "all"
    set src "all"
    set priority-members 1
next
edit 2
    set name "Secondary-Out"
    set role secondary
    set dst "all"
    set src "all"
    set priority-members 2
next
end
end

```

If neither the primary nor secondary neighbors are active, the SD-WAN neighbor status becomes standalone. Only service rules with `standalone-action` enabled will continue to pass traffic. This option is disabled by default.

Verification

To verify when the primary neighbor is passing traffic:

1. Verify the health check status:

```

FortiGate-Branch # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(0.569), jitter(0.061) sla_
map=0x1

```

```
Health Check(ping2):
Seq(2 port2): state(alive), packet-loss(0.000%) latency(3.916), jitter(2.373) sla_
map=0x1
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
    Selected role(primary) last_secondary_select_time/current_time in seconds 0/572
Neighbor(10.100.1.1): member(1) role(primary)
    Health-check(ping:1) sla-pass selected alive
Neighbor(10.100.1.5): member(2) role(secondary)
    Health-check(ping2:1) sla-pass alive
```

3. Verify service rules status:

```
FortiGate-Branch # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Service role: primary
Members:
    1: Seq_num(1 port1), alive, selected
Src address:
    0.0.0.0-255.255.255.255

Dst address:
    0.0.0.0-255.255.255.255

Service(2): Address Mode(IPV4) flags=0x0
Gen(6), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Service role: secondary, disabled by unselected.
Members:
    1: Seq_num(2 port2), alive, selected
Src address:
    0.0.0.0-255.255.255.255

Dst address:
    0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:

a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
    Not advertised to any peer
    64512
    10.100.1.2 from 10.100.1.2 (192.168.122.98)
        Origin IGP metric 0, localpref 100, valid, external, best
    Community: 20:1
    Last update: Thu Apr 30 13:41:40 2020
```

b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
    Not advertised to any peer
```

```
Original VRF 0
64512
10.100.1.6 from 10.100.1.6 (192.168.122.98)
Origin IGP metric 0, localpref 100, valid, external, best
Community: 20:5
Last update: Thu Apr 30 13:41:39 2020
```

To verify when the secondary neighbor is passing traffic:

1. Verify the health check status:

```
FortiGate-Branch # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 port1): state(dead), packet-loss(54.000%) sla_map=0x0
Health Check(ping2):
Seq(2 port2): state(alive), packet-loss(0.000%) latency(4.339), jitter(3.701) sla_map=0x1
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
Selected role(secondary) last_secondary_select_time/current_time in seconds
936/936
Neighbor(10.100.1.1): member(1) role(primary)
Health-check(ping:1) sla-fail dead
Neighbor(10.100.1.5): member(2) role(secondary)
Health-check(ping2:1) sla-pass selected alive
```

3. Verify service rules status:

```
FortiGate-Branch # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
Gen(4), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Service role: primary, disabled by unselected.
Members:
1: Seq_num(1 port1), alive, selected
Src address:
0.0.0.0-255.255.255.255

Dst address:
0.0.0.0-255.255.255.255

Service(2): Address Mode(IPV4) flags=0x0
Gen(7), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Service role: secondary
Members:
1: Seq_num(2 port2), alive, selected
Src address:
0.0.0.0-255.255.255.255

Dst address:
0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:

a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    10.100.1.2 from 10.100.1.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:5
      Last update: Thu Apr 30 15:41:58 2020
```

b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    10.100.1.6 from 10.100.1.6 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:2
      Last update: Thu Apr 30 15:42:07 2020
```

Applying BGP route-map to multiple BGP neighbors

[Controlling traffic with BGP route mapping and service rules](#) explained how BGP can apply different route-maps to the primary and secondary SD-WAN neighbors based on SLA health checks.

In this example, SD-WAN neighbors that are not bound to primary and secondary roles are configured.

The FortiGate has multiple SD-WAN links and has formed BGP neighbors with both ISPs.

ISP1 is used primarily for outbound traffic, and has an SD-WAN service rule using the lowest cost algorithm applied to it. When SLAs for ISP1 are not met, it will fail over to the MPLS line.

Inbound traffic is allowed by both WAN links, with each WAN advertising a community string when SLAs are met. When SLAs are not met, the WAN links advertise a different community string.

This example uses two SD-WAN links. The topology can be expanded to include more links as needed.

To configure BGP route-maps and neighbors:**1. Configure an access list for routes to be matched:**

```
config router access-list
  edit "net192"
    config rule
      edit 1
        set prefix 192.168.20.0 255.255.255.0
      next
    end
  next
end
```

2. Configure route-maps for neighbor ISP1:

```
config router route-map
  edit "comm1"
    config rule
      edit 1
        set match-ip-address "net192"
        set set-community "64511:1"
      next
    end
  next
  edit "comm-fail1"
    config rule
      edit 1
        set match-ip-address "net192"
        set set-community "64511:5"
      next
    end
  next
end
```

3. Configure route-maps for neighbor ISP2:

```
config router route-map
  edit "comm2"
    config rule
      edit 1
        set match-ip-address "net192"
        set set-community "64522:1"
      next
    end
  next
  edit "comm-fail2"
    config rule
      edit 1
        set match-ip-address "net192"
        set set-community "64522:5"
      next
    end
  next
end
```

4. Configure the BGP neighbors:

```

config router bgp
  set as 64512
  set keepalive-timer 1
  set holdtime-timer 3
  config neighbor
    edit "192.168.2.1"
      set soft-reconfiguration enable
      set remote-as 64511
      set route-map-out "comm-fail1"
      set route-map-out-preferable "comm1"
    next
    edit "172.31.0.1"
      set soft-reconfiguration enable
      set remote-as 64522
      set route-map-out "comm-fail2"
      set route-map-out-preferable "comm2"
    next
  end
  config network
    edit 1
      set prefix 192.168.20.0 255.255.255.0
    next
  end
end

```

When SLAs are met, `route-map-out-preferable` is used. When SLAs are missed, `route-map-out` is used.

To configure SD-WAN:**1. Configure the SD-WAN members:**

```

config system sdwan
  set status enable
  config members
    edit 1
      set interface "port1"
      set gateway 192.168.2.1
    next
    edit 2
      set interface "MPLS"
      set cost 20
    next
  end
end

```

2. Configure the health checks that must be met:

```

config system sdwan
  config health-check
    edit "pingserver"
      set server "8.8.8.8"
      set members 2 1
      config sla
        edit 1
          set link-cost-factor packet-loss
          set packetloss-threshold 2
        next
      next
    next
  end
end

```

```

        next
    end
    next
end
end

```

3. Configure the SD-WAN neighbors and assign them a role and the health checks used to determine if the neighbor meets the SLA:

When no role is defined, the default role, `standalone`, is used.

```

config system sdwan
    config neighbor
        edit "192.168.2.1"
            set member 1
            set health-check "pingserver"
            set sla-id 1
        next
        edit "172.31.0.1"
            set member 2
            set health-check "pingserver"
            set sla-id 1
        next
    end
end

```

Service rules

Create SD-WAN service rules to direct traffic to the SD-WAN links based on the lowest cost algorithm. The same SLA health check and criteria that are used for the SD-WAN neighbor are used for this SD-WAN service rule.

When no roles are defined in the service rule, the default role, `standalone`, is used.

To configure the SD-WAN service rule:

```

config system sdwan
    config service
        edit 1
            set name "OutboundAll"
            set mode sla
            set dst "all"
            set src "all"
            config sla
                edit "pingserver"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end

```

Verification

To verify that when both SLAs are met, port1 is selected due to its lower cost:

1. Verify the health check status:

```
FortiGate-Branch # diagnose sys sdwan health-check
Health Check(pingserver):
Seq(2 MPLS): state(alive), packet-loss(0.000%) latency(24.709), jitter(14.996) sla_
map=0x1
Seq(1 port1): state(alive), packet-loss(0.000%) latency(28.771), jitter(14.840) sla_
map=0x1
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
Neighbor(192.168.2.1): member(1) role(standalone)
Health-check(pingserver:1) sla-pass selected alive
Neighbor(172.31.0.1): member(2) role(standalone)
Health-check(pingserver:1) sla-pass selected alive
```

3. Verify service rules status:

Because the service role is standalone, it matches both neighbors. The mode (SLA) determines that port1 is lower cost.

```
FortiGate-Branch # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Service role: standalone
Members:
1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
2: Seq_num(2 MPLS), alive, sla(0x1), cfg_order(1), cost(20), selected
Src address:
0.0.0.0-255.255.255.255

Dst address:
0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:

a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
Not advertised to any peer
64512
192.168.2.5 from 192.168.2.5 (192.168.122.98)
Origin IGP metric 0, localpref 100, valid, external, best
Community: 64511:1
Last update: Thu Apr 30 23:59:05 2020
```

b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
Not advertised to any peer
Original VRF 0
```

```

64512
172.31.0.2 from 172.31.0.2 (192.168.122.98)
  Origin IGP metric 0, localpref 100, valid, external, best
  Community: 64522:1
  Last update: Fri May 1 00:11:28 2020

```

To verify that when neighbor ISP1 misses SLAs, MPLS is selected and BGP advertises a different community string for ISP1:

1. Verify the health check status:

```

FortiGate-Branch # diagnose sys sdwan health-check
Health Check(pingserver):
Seq(2 MPLS): state(alive), packet-loss(0.000%) latency(25.637), jitter(17.820) sla_
map=0x1
Seq(1 port1): state(dead), packet-loss(16.000%) sla_map=0x0

```

2. Verify SD-WAN neighbor status:

```

FortiGate-Branch # diagnose sys sdwan neighbor
Neighbor(192.168.2.1): member(1) role(standalone)
  Health-check(pingserver:1) sla-fail dead
Neighbor(172.31.0.1): member(2) role(standalone)
  Health-check(pingserver:1) sla-pass selected alive

```

3. Verify service rules status:

As SLA failed for neighbor ISP1, MPLS is preferred.

```

FortiGate-Branch # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
  Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Service role: standalone
  Members:
    1: Seq_num(2 MPLS), alive, sla(0x1), cfg_order(1), cost(20), selected
    2: Seq_num(1 port1), dead, sla(0x0), cfg_order(0), cost(0)
  Src address:
    0.0.0.0-255.255.255.255

  Dst address:
    0.0.0.0-255.255.255.255

```

4. Verify neighbor routers:

The community received on ISP1 is updated.

a. Primary neighbor router:

```

FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
64512
192.168.2.5 from 192.168.2.5 (192.168.122.98)
  Origin IGP metric 0, localpref 100, valid, external, best
  Community: 64511:5
  Last update: Fri May 1 00:33:26 2020

```

b. Secondary neighbor router:

```

FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
    Not advertised to any peer
    Original VRF 0
    64512
    172.31.0.2 from 172.31.0.2 (192.168.122.98)
    Origin IGP metric 0, localpref 100, valid, external, best
    Community: 64522:1

```

Using multiple members per SD-WAN neighbor configuration

SD-WAN BGP neighbor configurations are used to define the SLA health check in which an SD-WAN member must meet to qualify as being up. When the SD-WAN member meets the SLA threshold, the FortiGate will apply the route map defined in the BGP neighbor's `route-map-out-preferable` option. If the SD-WAN member fails to meet the SLA, the FortiGate will apply the route map defined in the BGP neighbor's `route-map-out` option instead. This allows the FortiGate to advertise the health of the SD-WAN member to its BGP neighbor by advertising different community strings based on its SLA status.

For more information, refer to the following BGP examples: [Controlling traffic with BGP route mapping and service rules on page 870](#) and [Applying BGP route-map to multiple BGP neighbors on page 877](#).

Selecting multiple SD-WAN members allows the SD-WAN neighbor feature to support topologies where there are multiple SD-WAN overlays and/or underlays to a neighbor. The `minimum-sla-meet-members` option is used to configure the minimum number of members that must be in an SLA per neighbor for the preferable route map to be used.

```

config system sdwan
    config neighbor
        edit <ip>
            set member {<seq-num_1>} [<seq-num_2>] ... [<seq-num_n>]
            set minimum-sla-meet-members <integer>
        next
    end
end

```

<pre>member {<seq-num_1>} [<seq-num_2>] ... [<seq-num_n>]</pre>	Enter the member sequence number list. Multiple members can be defined.
<pre>minimum-sla-meet-members <integer></pre>	<p>Set the minimum number of members that meet SLA when the neighbor is preferred (1 - 255, default = 1).</p> <ul style="list-style-type: none"> • If the number of in SLA members is less than the <code>minimum-sla-meet-members</code> value, the default route map will be used. • If the number of in SLA members is equal or larger than the <code>minimum-sla-meet-members</code> value, the preferable route map will be used.

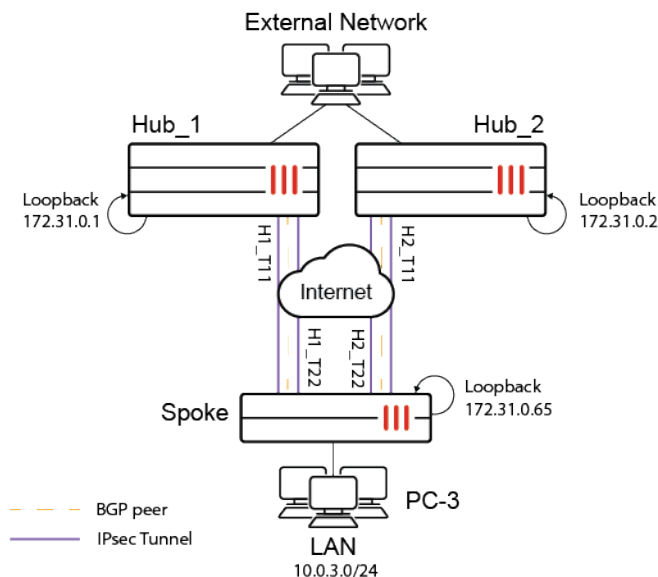

Example

In the following example, the spoke FortiGate has four tunnels: two tunnels to Hub_1 and two tunnels to Hub_2. The spoke has two BGP neighbors: one to Hub_1 and one to Hub_2. BGP neighbors are established on loopback IPs.

The SD-WAN neighbor plus `route-map-out-preferable` configuration is deployed on the spoke to achieve the following:

- If any tunnel to Hub_1 or Hub_2 is in SLA, the preferable route map will be applied on the BGP neighbor to Hub_1 or Hub_2.
- If both tunnels to Hub_1 or Hub_2 are out of SLA, the default route map will be applied on the BGP neighbor to Hub_1 or Hub_2.

The preferable route map and default route map are used to set different custom BGP communities as the spoke advertises its LAN routes to the hub. Each hub can translate communities into different BGP MED or AS prepends and signal them to the external peers to manipulate inbound traffic, thereby routing traffic to the spoke only when the SLAs are met on at least one of two VPN overlays. In this example, community string 10:1 signals to the neighbor that SLAs are met, and 10:2 signals that SLAs are not met.

To configure the BGP route maps and neighbors:

1. Configure an access list of prefixes to be matched:

```
config router access-list
  edit "net10"
    config rule
      edit 1
        set prefix 10.0.3.0 255.255.255.0
      next
    end
  next
end
```

2. Configure route maps for neighbors in SLA (preferable) and out of SLA (default):

```

config router route-map
  edit "in_sla"
    config rule
      edit 1
        set match-ip-address "net10"
        set set-community "10:1"
      next
    end
  next
  edit "out_sla"
    config rule
      edit 1
        set match-ip-address "net10"
        set set-community "10:2"
      next
    end
  next
end

```

3. Configure the BGP neighbors:

```

config router bgp
  set router-id 172.31.0.65
  config neighbor
    edit "172.31.0.1"
      set route-map-out "out_sla"
      set route-map-out-preferable "in_sla"
      set update-source "Loopback0"
    next
    edit "172.31.0.2"
      set route-map-out "out_sla"
      set route-map-out-preferable "in_sla"
      set update-source "Loopback0"
    next
  end
  config network
    edit 1
      set prefix 10.0.3.0 255.255.255.0
    next
  end
end

```

To configure SD-WAN:**1. Configure the SD-WAN members:**

```

config system sdwan
  set status enable
  config members
    edit 1
      set interface "H1_T11"
      set source 172.31.0.65
    next
    edit 4
      set interface "H1_T22"

```

```

        set source 172.31.0.65
    next
    edit 6
        set interface "H2_T11"
        set source 172.31.0.65
    next
    edit 9
        set interface "H2_T22"
        set source 172.31.0.65
    next
end
end

```

2. Configure the health check that must be met:

```

config system sdwan
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set members 0
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
            end
        next
    end
end

```

3. Configure the SD-WAN neighbors:

```

config system sdwan
    config neighbor
        edit "172.31.0.1"
            set member 1 4
            set health-check "HUB"
            set sla-id 1
            set minimum-sla-meet-members 1
        next
        edit "172.31.0.2"
            set member 6 9
            set health-check "HUB"
            set sla-id 1
            set minimum-sla-meet-members 1
        next
    end
end

```

To verify that when two members to Hub_1/Hub_2 are in SLA, the preferable route map is be applied on BGP neighbors to Hub_1/Hub_2:

```

Branch1_A_FGT (root) # diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(0.209), jitter(0.017), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.171), jitter(0.004), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1

```

```
Seq(6 H2_T11): state(alive), packet-loss(0.000%) latency(0.175), jitter(0.014), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(9 H2_T22): state(alive), packet-loss(0.000%) latency(0.176), jitter(0.019), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1

# diagnose sys sdwan neighbor
Neighbor(172.31.0.1): member(1 4 )role(standalone)
    Health-check(HUB:1) sla-pass selected alive
Neighbor(172.31.0.2): member(6 9 )role(standalone)
    Health-check(HUB:1) sla-pass selected alive
```

On Hub_1 and Hub_2, the expected communities have been attached into the spoke's LAN route:

```
Hub_1_FGT (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
    Not advertised to any peer
    Original VRF 0
    Local, (Received from a RR-client)
    172.31.0.65 from 172.31.0.65 (172.31.0.65)
    Origin IGP metric 0, localpref 100, valid, internal, best
    Community: 10:1
    Last update: Wed Dec 29 22:38:29 2021

Hub_2_FGT (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
    Not advertised to any peer
    Original VRF 0
    Local, (Received from a RR-client)
    172.31.0.65 from 172.31.0.65 (172.31.0.65)
    Origin IGP metric 0, localpref 100, valid, internal, best
    Community: 10:1

    Last update: Wed Dec 29 22:43:10 2021
```

If one member for each neighbor becomes out of SLA, the preferable route map is still applied:

```
Branch1_A_FGT (root) # diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(120.207), jitter(0.018), mos
(4.338), bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x0
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.182), jitter(0.008), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1
Seq(6 H2_T11): state(alive), packet-loss(0.000%) latency(120.102), jitter(0.009), mos
(4.404), bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x0
Seq(9 H2_T22): state(alive), packet-loss(0.000%) latency(0.176), jitter(0.009), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1

# diagnose sys sdwan neighbor
Neighbor(172.31.0.1): member(1 4 )role(standalone)
    Health-check(HUB:1) sla-pass selected alive
Neighbor(172.31.0.2): member(6 9 )role(standalone)
    Health-check(HUB:1) sla-pass selected alive

Hub_1_FGT (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
    Not advertised to any peer
```

```

ADVPN and shortcut paths

This topic provides an example of how to use SD-WAN and ADVPN together.

ADVPN (Auto Discovery VPN) is an IPsec technology that allows a traditional hub-and-spoke VPN's spokes to establish dynamic, on-demand, direct tunnels between each other to avoid routing through the topology's hub device. The primary advantage is that it provides full meshing capabilities to a standard hub-and-spoke topology. This greatly reduces the provisioning effort for full spoke-to-spoke low delay reachability, and addresses the scalability issues associated with very large fully meshed VPN networks.

If a customer's head office and branch offices all have two or more internet connections, they can build a dual-hub ADVPN network. Combined with SD-WAN technology, the customer can load-balance traffic to other offices on multiple dynamic tunnels, control specific traffic using specific connections, or choose better performance connections dynamically.

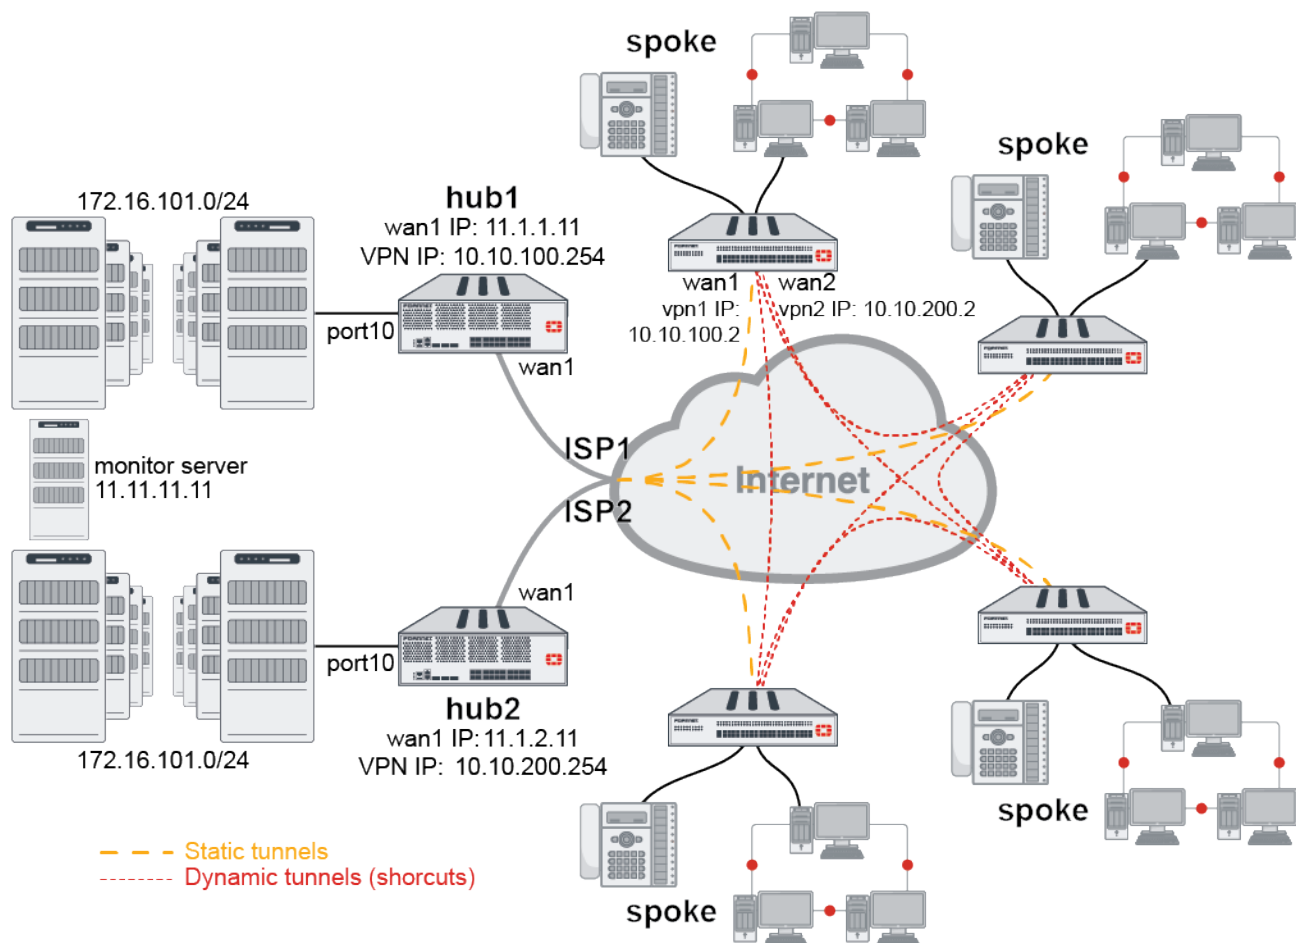

SD-WAN load-balance mode rules (or services) do not support ADVPN members. Other modes' rules, such as SLA and priority, support ADVPN members.

This topic covers three parts:

1. Configure dual-hub ADVPN with multiple branches.
2. Configure BGP to exchange routing information among hubs and spokes.
3. Configure SD-WAN on spoke to do load-balancing and control traffic.

Configuration example

A typical ADVPN configuration with SD-WAN usually has two hubs, and each spoke connects to two ISPs and establishes VPN tunnels with both hubs.

This example shows a hub-and-spoke configuration using two hubs and one spoke:

- Hub1 and Hub2 both use wan1 to connect to the ISPs and port10 to connect to internal network.
- Spoke1 uses wan1 to connect to ISP1 and wan2 to connect to ISP2.
- wan1 sets up VPN to hub1.
- wan2 sets up VPN to hub2.

The SD-WAN is configured on the spoke. It uses the two VPN interfaces as members and two rules to control traffic to headquarters or other spokes using ADVPN VPN interfaces. You can create more rules if required.

For this example:

- Use SD-WAN member 1 (via ISP1) and its dynamic shortcuts for financial department traffic if member 1 meets SLA requirements. If it doesn't meet SLA requirements, it will use SD-WAN member 2 (via ISP2).
- Use SD-WAN member 2 (via ISP2) and its dynamic shortcuts for engineering department traffic.
- Load balance other traffic going to hubs and other spokes between these two members.
- Set up all other traffic to go with their original ISP connection. All other traffic does not go through SD-WAN.
- Set up basic network configuration to let all hubs and spokes connect to their ISPs and the Internet.

Hub internal network	172.16.101.0/24
Spoke1 internal network	10.1.100.0/24
ADVPN 1 network	10.10.100.0/24
ADVPN 2 network	10.10.200.0/24
Hub1 wan1 IP	11.1.1.11
Hub2 wan1 IP	11.1.2.11
Hub1 VPN IP	10.10.100.254
Hub2 VPN IP	10.10.200.254
Spoke1 to hub1 VPN IP	10.10.100.2
Spoke1 to hub2 VPN IP	10.10.200.2
Ping server in Headquarters	11.11.11.11
Internal subnet of spoke1	22.1.1.0/24
Internal subnet of spoke2	33.1.1.0/24
Firewall addresses	Configure hub_subnets and spoke_subnets before using in policies. These can be customized.

The GUI does not support some ADVPN related options, such as auto-discovery-sender, auto-discovery-receiver, auto-discovery-forwarder, and IBGP neighbor-group setting, so this example only provides CLI configuration commands.

Hub1 sample configuration

To configure the IPsec phase1 and phase2 interface:

```
config vpn ipsec phase1-interface
    edit "hub-phase1"
        set type dynamic
        set interface "wan1"
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 3des-sha256 aes128-sha1 aes256-sha1 3des-
sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-sender enable
        set psksecret sample
        set dpd-retryinterval 5
    next
end
config vpn ipsec phase2-interface
    edit "hub-phase2"
        set phase1name "hub-phase1"
        set proposal aes128-sha1 aes256-sha1 3des-sha1 aes128-sha256 aes256-sha256 3des-
sha256
    next
end
```

When `net-device` is disabled, a tunnel ID is generated for each dynamic tunnel. This ID, in the form of an IP address, is used as the gateway in the route entry to that tunnel. The `tunnel-search` option is removed in FortiOS 7.0.0 and later.

To configure the VPN interface and BGP:

```
config system interface
  edit "hub-phase1"
    set ip 10.10.100.254 255.255.255.255
    set remote-ip 10.10.100.253 255.255.255.0
  next
end
config router bgp
  set as 65505
  config neighbor-group
    edit "advpn"
      set link-down-failover enable
      set remote-as 65505
      set route-reflector-client enable
    next
  end
  config neighbor-range
    edit 1
      set prefix 10.10.100.0 255.255.255.0
      set neighbor-group "advpn"
    next
  end
  config network
    edit 1
      set prefix 172.16.101.0 255.255.255.0
    next
    edit 2
      set prefix 11.11.11.0 255.255.255.0
    next
  end
end
```

To configure the firewall policy:

```
config firewall policy
  edit 1
    set name "spoke2hub"
    set srcintf "hub-phase1"
    set dstintf "port10"
    set srcaddr "spoke_subnets"
    set dstaddr "hub_subnets"
    set action accept
    set schedule "always"
    set service "ALL"
    set comments "allow traffic from spokes to headquarter"
  next
  edit 2
    set name "spoke2spoke"
    set srcintf "hub-phase1"
```

```

        set dstintf "hub-phase1"
        set srcaddr "spoke_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from spokes to spokes"
    next
    edit 3
        set name "internal2spoke"
        set srcintf "port10"
        set dstintf "hub-phase1"
        set srcaddr "hub_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from headquarter to spokes"
    next
end

```

Hub2 sample configuration

Hub2 configuration is the same as hub1 except the wan1 IP address, VPN interface IP address, and BGP neighbor-range prefix.

To configure the IPsec phase1 and phase2 interface:

```

config vpn ipsec phase1-interface
    edit "hub-phase1"
        set type dynamic
        set interface "wan1"
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 3des-sha256 aes128-sha1 aes256-sha1 3des-
sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-sender enable
        set psksecret sample
        set dpd-retryinterval 5
    next
end
config vpn ipsec phase2-interface
    edit "hub-phase2"
        set phase1name "hub-phase1"
        set proposal aes128-sha1 aes256-sha1 3des-sha1 aes128-sha256 aes256-sha256 3des-
sha256
    next
end

```

To configure the VPN interface and BGP:

```

config system interface
    edit "hub-phase1"

```

```
        set ip 10.10.200.254 255.255.255.255
        set remote-ip 10.10.200.253 255.255.255.0

        set comments "allow traffic from headquarter to spokes"
    next
end

```

Spoke1 sample configuration

To configure the IPsec phase1 and phase2 interface:

```

config vpn ipsec phase1-interface
    edit "spoke1-phase1"
        set interface "wan1"
        set peertype any
        set net-device enable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-receiver enable
        set remote-gw 11.1.1.11
        set psksecret sample
        set dpd-retryinterval 5
    next
    edit "spoke1-2-phase1"
        set interface "wan2"
        set peertype any
        set net-device enable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-receiver enable
        set remote-gw 11.1.2.11
        set psksecret sample
        set dpd-retryinterval 5
    next
end
config vpn ipsec phase2-interface
    edit "spoke1-phase2"
        set phase1name "spoke1-phase1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm aes256gcm
chacha20poly1305
        set auto-negotiate enable
    next
    edit "spoke1-2-phase2"
        set phase1name "spoke1-2-phase1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm aes256gcm
chacha20poly1305
        set auto-negotiate enable
    next
end

```

To configure the VPN interface and BGP:

```
config system interface
    edit "spoke1-phase1"
        set ip 10.10.100.2 255.255.255.255
        set remote-ip 10.10.100.254 255.255.255.0
    next
    edit "spoke1-2-phase1"
        set ip 10.10.200.2 255.255.255.255
        set remote-ip 10.10.200.254 255.255.255.0
    next
end
config router bgp
    set as 65505
    config neighbor
        edit "10.10.100.254"
            set advertisement-interval 1
            set link-down-failover enable
            set remote-as 65505
        next
        edit "10.10.200.254"
            set advertisement-interval 1
            set link-down-failover enable
            set remote-as 65505
        next
    end
    config network
        edit 1
            set prefix 10.1.100.0 255.255.255.0
        next
    end
end
```

To configure SD-WAN:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "spoke1-phase1"
        next
        edit 2
            set interface "spoke1-2-phase1"
        next
    end
    config health-check
        edit "ping"
            set server "11.11.11.11"
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 200
                    set jitter-threshold 50
                    set packetloss-threshold 5
                next
            end
        end
    end
```

```
        next
    end
    config service
        edit 1
            set mode sla
            set dst "financial-department"
            config sla
                edit "ping"
                    set id 1
                next
            end
            set priority-members 1 2
        next
        edit 2
            set priority-members 2
            set dst "engineering-department"
        next
    end
end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To configure the firewall policy:

```
config firewall policy
    edit 1
        set name "outbound_advpn"
        set srcintf "internal"
        set dstintf "virtual-wan-link"
        set srcaddr "spoke_subnets"
        set dstaddr "spoke_subnets" "hub_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow internal traffic going out to headquarter and other spokes"
    next
    edit 2
        set name "inbound_advpn"
        set srcintf "virtual-wan-link"
        set dstintf "internal"
        set srcaddr "spoke_subnets" "hub_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow headquarter and other spokes traffic coming in"
    next
end
```

Troubleshooting ADVPN and shortcut paths

Before spoke vs spoke shortcut VPN is established

Use the following CLI commands to check status before spoke vs spoke shortcut VPN is established.

get router info bgp summary

```
BGP router identifier 2.2.2.2, local AS number 65505
BGP table version is 13
3 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd

Active dynamic BGP neighbor triggered by ADVPN shortcut - NEW

When a customer using SD-WAN with ADVPN has numerous IPv4 and IPv6 routes per spoke and there are many spokes in the topology, using ADVPN with a route reflector-based design poses the following challenges:

- The hub FortiGate will experience high CPU usage due to the amount of processing required to reflect the routes to the spoke FortiGates.
- Spoke FortiGates will learn many unnecessary routes.

For such cases, it is more suitable to deploy an IPv4- and IPv6-supported solution without a route-reflector that involves an active dynamic BGP neighbor triggered by an ADVPN shortcut. This solution allows a spoke FortiGate to form a BGP neighbor with another spoke FortiGate only after the shortcut tunnel between them has been established. As a result, the spoke only learns routes from its BGP neighbors.

How this solution differs from typical SD-WAN with ADVPN

In a topology where the Spoke 1 and Spoke 2 FortiGates are connected directly to the Hub FortiGate, route reflection will not be enabled. The Hub FortiGate is only configured with each spoke's summary route. An ADVPN shortcut tunnel is established between the Spoke 1 and Spoke 2 FortiGates. The valid routing between the Spoke 1 and Spoke 2 FortiGate is still through the Hub FortiGate at this point.

When a host behind Spoke 1 tries to connect to a host behind Spoke 2, Spoke 1 first reaches the Hub based on the valid routing table. The Hub determines that the destination is reachable, and the ADVPN shortcut tunnel between the spokes is established. Then, Spoke 1 and Spoke 2 will actively initiate a BGP connection to each other over the shortcut. Once established, they will exchange their routing information using BGP. On both spokes, BGP will resolve those routes on the shortcut and update the routing table accordingly.

For this solution, the following IPv4/IPv6 BGP configuration settings are required:

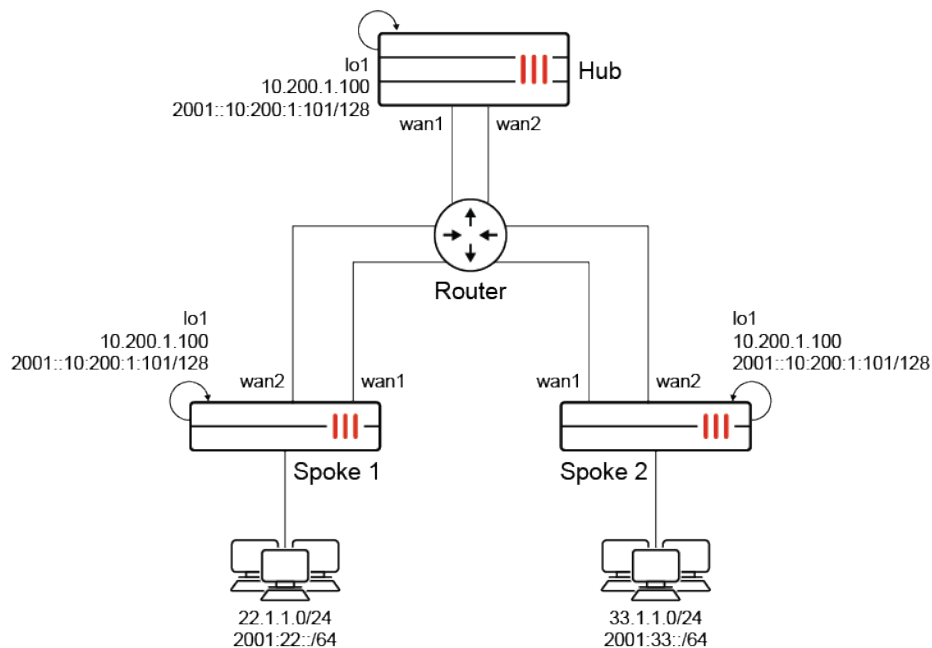

- The hub FortiGate should be configured with `neighbor-group` and `neighbor-range/neighbor-range6`.
- Each spoke FortiGate should be configured with `neighbor-group` and `neighbor-range/neighbor-range6` like the hub. More importantly, each spoke should be configured with `set passive disable` to ensure spokes are able to initiate dynamic BGP connections between each other.
- The hub FortiGate should have route reflection disabled (by default) where each `neighbor-group` setting should have `set route-reflector-client disable`.

In the configuration, each of the spokes will form a BGP neighbor relationship with the hub. This is unchanged from the typical SD-WAN with ADVPN configuration.

Example

This example configuration contains the following structure:

- Use SD-WAN member 1 (via ISP1) and its dynamic shortcuts for Financial Department traffic.
- Use SD-WAN member 2 (via ISP2) and its dynamic shortcuts for Engineering Department traffic.
- Internal subnets of Spoke 1:
 - IPv4: 22.1.1.0/24
 - IPv6: 2001:22::/64
- Internal subnets of Spoke 2:
 - IPv4: 33.1.1.0/24
 - Financial Department: 33.1.1.1 to 33.1.1.100
 - Engineering Department: 33.1.1.101 to 33.1.1.200
 - IPv6: 2001:33::/64
 - Financial Department: 2001:33::1 to 2001:33::100
 - Engineering Department: 2001:33::101 to 2001:33::200

To configure the Hub FortiGate:**1. Configure the BGP settings (neighbor group and ranges):**

```

config router bgp
    set as 65100
    set router-id 10.200.1.1
    set ibgp-multipath enable
    config neighbor-group
        edit "EDGE"
            set activate6 disable
            set remote-as 65100
            set update-source "lo1"
            set route-reflector-client disable
        next
        edit "EDGEv6"
            set activate disable
            set remote-as 65100
            set update-source "lo1"
            set route-reflector-client disable
        next
    end
    config neighbor-range
        edit 2
            set prefix 10.200.1.0 255.255.255.0
            set neighbor-group "EDGE"
        next
    end
    config neighbor-range6
        edit 2
            set prefix6 2001::10:200:1:0/112
            set neighbor-group "EDGEv6"
        next
    end
    config network
        edit 2
            set prefix 10.200.1.0 255.255.255.0
        next
        edit 4
            set prefix 33.0.0.0 255.0.0.0
        next
        edit 5
            set prefix 22.0.0.0 255.0.0.0
        next
    end
    config network6
        edit 4
            set prefix6 2001:33::/32
        next
        edit 2
            set prefix6 2001:22::/32
        next
    end
end

```

2. Configure the static routes.

a. For IPv4:

```
config router static
  edit 33
    set dst 33.0.0.0 255.0.0.0
    set blackhole enable
    set vrf 0
  next
  edit 22
    set dst 22.0.0.0 255.0.0.0
    set blackhole enable
    set vrf 0
  next
end
```

b. For IPv6:

```
config router static6
  edit 33
    set dst 2001:33::/32
    set blackhole enable
    set vrf 0
  next
  edit 22
    set dst 2001:22::/32
    set blackhole enable
    set vrf 0
  next
end
```

The following IPv4 summary routes are advertised:

- 33.0.0.0/8
- 22.0.0.0/8

The following IPv6 summary routes are advertised:

- 2001:33::/32
- 2001:22::/32

Because route reflection has been disabled in this example, initially, Spoke 1 will not know the local subnet of Spoke 2, and Spoke 2 will not know the local subnet of Spoke 1. Therefore, for traffic routing, summary routes are configured on the hub as blackhole routes and then advertised to the spokes using BGP.

For example, for traffic from the local subnet of Spoke 2 destined for the local subnet of Spoke 1:

- For the IPv4 case, the summary route 22.0.0.0/8, which includes the local subnet of Spoke 1 (22.1.1.0/24), is advertised to Spoke 2. When Spoke 2 sends traffic destined for 22.1.1.0/24 to the Hub, the Hub forwards this traffic to Spoke 1 since they are BGP neighbors.
- For the IPv6 case, the summary route 2001:22::/32, which includes the local subnet of Spoke 1 (2001:22::/64), is advertised to Spoke 2. When Spoke 2 sends traffic destined for 2001:22::/64 to the Hub, the Hub forwards this traffic to Spoke 1 since they are BGP neighbors.

Although traffic from spoke-to-spoke goes through the hub first, it is expected that the spoke will eventually go through the shortcut tunnel.

To configure the Spoke 1 FortiGate:**1. Configure the SD-WAN settings:**

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "spoke1-1"
            set cost 10
        next
        edit 2
            set interface "spoke-2"
            set cost 20
        next
    end
    config health-check
        edit "ping"
            set server "11.11.11.11"
            set source 10.200.1.100
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 200
                    set jitter-threshold 50
                next
            end
        next
    end
    config service
        edit 1
            set dst "financial-department"
            set priority-members 1
        next
        edit 2
            set dst "engineering-department"
            set priority-members 2
        next
        edit 61
            set addr-mode ipv6
            set priority-members 1
            set dst6 "financial-department-IPv6"
        next
        edit 62
            set addr-mode ipv6
            set priority-members 2
            set dst6 "engineering-department-IPv6"
        next
    end
end
```

2. Configure the BGP settings (neighbor group and ranges):

```
config router bgp
  set as 65100
  set router-id 10.200.1.100
  set ibgp-multipath enable
  config neighbor
    edit "10.200.1.1"
      set activate6 disable
      set remote-as 65100
      set connect-timer 10
      set update-source "lo1"
    next
    edit "2001::10:200:1:1"
      set advertisement-interval 1
      set activate disable
      set remote-as 65100
      set update-source "lo1"
    next
  end
  config neighbor-group
    edit "spokes"
      set activate6 disable
      set passive disable
      set remote-as 65100
      set update-source "lo1"
    next
    edit "spokesv6"
      set activate disable
      set passive disable
      set remote-as 65100
      set update-source "lo1"
    next
  end
  config neighbor-range
    edit 1
      set prefix 10.200.1.0 255.255.255.0
      set neighbor-group "spokes"
    next
  end
  config neighbor-range6
    edit 1
      set prefix6 2001::10:200:1:0/112
      set neighbor-group "spokesv6"
    next
  end
  config network
    edit 3
      set prefix 22.1.1.0 255.255.255.0
    next
  end
  config network6
    edit 1
      set prefix6 2001:22::/64
    next
  end
end
```

Verifying the configuration before a spoke-to-spoke shortcut VPN is established

IPv4 use case

To verify the status on Spoke 1:

1. Verify the BGP status:

```
# get router info bgp summary
VRF 0 BGP router identifier 10.200.1.100, local AS number 65100
BGP table version is 5
1 BGP AS-PATH entries
0 BGP community entries
Neighbor    V      AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
10.200.1.1  4      65100   222    225       3    0    0 00:15:14      3
Total number of neighbors 1
```

2. Verify the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B      11.11.11.11/32 [200/0] via 10.200.1.1 (recursive via spoke1-1 tunnel 11.1.1.11),
00:15:19
                                         (recursive via spoke1-2 tunnel
111.1.1.11), 00:15:19, [1/0]
B      22.0.0.0/8 [200/0] via 10.200.1.1 (recursive via spoke1-1 tunnel 11.1.1.11),
00:15:19
                                         (recursive via spoke1-2 tunnel 111.1.1.11),
00:15:19, [1/0]
B      33.0.0.0/8 [200/0] via 10.200.1.1 (recursive via spoke1-1 tunnel 11.1.1.11),
00:15:19
                                         (recursive via spoke1-2 tunnel 111.1.1.11),
00:15:19, [1/0]
```

IPv6 use case

To verify the status on Spoke 1:

1. Verify the BGP status:

```
# get router info6 bgp summary
VRF 0 BGP router identifier 10.200.1.100, local AS number 65100
BGP table version is 6
1 BGP AS-PATH entries
0 BGP community entries
Neighbor    V      AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
2001::10:200:1:1  4      65100   223    224       4    0    0 00:15:21      3
Total number of neighbors 1
```

2. Verify the BGP routing table:

```
# get router info6 routing-table bgp
Routing table for VRF=0
B      2001::11:11:11:11/128 [200/0] via 2001::10:200:1:1 (recursive via spoke1-1
tunnel ::11.1.1.11), 00:15:29
                                         (recursive via spoke1-2
```

```

tunnel ::111.1.1.11), 00:15:29, [1024/0]
B      2001:22::/32 [200/0] via 2001::10:200:1:1 (recursive via spoke1-1 tunnel
::11.1.1.11), 00:15:29
                                         (recursive via spoke1-2 tunnel
::111.1.1.11), 00:15:29, [1024/0]
B      2001:33::/32 [200/0] via 2001::10:200:1:1 (recursive via spoke1-1 tunnel
::11.1.1.11), 00:15:29
                                         (recursive via spoke1-2 tunnel
::111.1.1.11), 00:15:29, [1024/0]

```

Verifying the configuration after a single spoke-to-spoke shortcut VPN is established

IPv4 use case

To trigger a single spoke-to-spoke shortcut VPN, on host 22.1.1.22, ping the host 33.1.1.33 in the Financial Department. Because of the SD-WAN rule, use SD-WAN member 1 (via ISP1) and its dynamic shortcuts to reach hosts in the Financial Department.

To verify the status on Spoke 1:

1. Verify the BGP status:

```

# get router info bgp summary
VRF 0 BGP router identifier 10.200.1.100, local AS number 65100
BGP table version is 6
1 BGP AS-PATH entries
0 BGP community entries
Neighbor      V      AS MsgRcvd MsgSent  TblVer  InQ OutQ Up/Down  State/PfxRcd
10.200.1.1    4      65100   252    254      3    0   0 00:17:22      3
10.200.1.101  4      65100     6     6      5    0   0 00:00:14      1
Total number of neighbors 2

```

Spoke 1 has as its BGP neighbors:

- Hub FortiGate at 10.200.1.1
- Spoke 2 FortiGate at 10.200.1.101

2. Verify the BGP routing table:

```

# get router info routing-table bgp
Routing table for VRF=0
B      11.11.11.11/32 [200/0] via 10.200.1.1 (recursive via spoke1-1 tunnel 11.1.1.11),
00:17:26
                                         (recursive via spoke1-2 tunnel
111.1.1.11), 00:17:26, [1/0]
B      22.0.0.0/8 [200/0] via 10.200.1.1 (recursive via spoke1-1 tunnel 11.1.1.11),
00:17:26
                                         (recursive via spoke1-2 tunnel 111.1.1.11),
00:17:26, [1/0]
B      33.0.0.0/8 [200/0] via 10.200.1.1 (recursive via spoke1-1 tunnel 11.1.1.11),
00:17:26
                                         (recursive via spoke1-2 tunnel 111.1.1.11),
00:17:26, [1/0]
B      33.1.1.0/24 [200/0] via 10.200.1.101 (recursive via spoke1-1_0 tunnel 13.1.1.3),
00:00:18, [1/0]

```

The remote route learned from Spoke 2 through the spoke1_1_0 tunnel and using BGP is 33.1.1.0/24.

IPv6 use case

To trigger a single spoke-to-spoke shortcut VPN over IPv6, on host 2001:22::22/64, ping the host 2001:33::33/64 in the Financial Department. Because of the SD-WAN rule, use SD-WAN member 1 (via ISP1) and its dynamic shortcuts to reach hosts in the Financial Department.

To verify the status on Spoke 1:

1. Verify the BGP status:

```
# get router info6 bgp summary
VRF 0 BGP router identifier 10.200.1.100, local AS number 65100
BGP table version is 7
1 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
2001::10:200:1:1	4	65100	253	254	4	0	0	00:17:28	3
2001::10:200:1:101	4	65100	7	7	6	0	0	00:00:21	1

```
Total number of neighbors 2
```

Spoke 1 has as its BGP neighbors:

- Hub FortiGate at 2001::10:200:1:1
- Spoke 2 FortiGate at 2001::10:200:1:101

2. Verify the BGP routing table:

```
# get router info6 routing-table bgp
Routing table for VRF=0
B      2001::11:11:11:11/128 [200/0] via 2001::10:200:1:1 (recursive via spoke1-1
tunnel ::11.1.1.11), 00:17:30
                                           (recursive via spoke1-2
tunnel ::111.1.1.11), 00:17:30, [1024/0]
B      2001:22::/32 [200/0] via 2001::10:200:1:1 (recursive via spoke1-1 tunnel
::11.1.1.11), 00:17:30
                                           (recursive via spoke1-2 tunnel
::111.1.1.11), 00:17:30, [1024/0]
B      2001:33::/32 [200/0] via 2001::10:200:1:1 (recursive via spoke1-1 tunnel
::11.1.1.11), 00:17:30
                                           (recursive via spoke1-2 tunnel
::111.1.1.11), 00:17:30, [1024/0]
B      2001:33::/64 [200/0] via 2001::10:200:1:101 (recursive via spoke1-1_0 tunnel
::13.1.1.3), 00:00:24, [1024/0]
```

The remote route learned from Spoke 2 through the spoke1-1_0 tunnel and using BGP is 2001:33::/64.

Verifying the configuration after a second spoke-to-spoke shortcut VPN is established

IPv4 use case

To trigger a second spoke-to-spoke shortcut VPN, on host 22.1.1.22, ping the host 33.1.1.133 in the Engineering Department. Because of the SD-WAN rule, use SD-WAN member 2 (via ISP2) and its dynamic shortcuts to reach hosts in the Engineering Department.

To verify the status on Spoke 1:**1. Verify the BGP status:**

```
# get router info bgp summary
VRF 0 BGP router identifier 10.200.1.100, local AS number 65100
BGP table version is 6
1 BGP AS-PATH entries
0 BGP community entries
Neighbor      V      AS MsgRcvd MsgSent   TblVer  InQ  OutQ Up/Down  State/PfxRcd
10.200.1.1    4      65100   263    265       3    0    0 00:18:12      3
10.200.1.101 4      65100    17     17       5    0    0 00:01:04      1
Total number of neighbors
```

Spoke 1 continues to have its BGP neighbors:

- Hub FortiGate at 10.200.1.1
- Spoke 2 FortiGate at 10.200.1.101

2. Verify the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B      11.11.11.11/32 [200/0] via 10.200.1.1 (recursive via spoke1-1 tunnel 11.1.1.11),
00:18:17
                                         (recursive via spoke1-2 tunnel
111.1.1.11), 00:18:17, [1/0]
B      22.0.0.0/8 [200/0] via 10.200.1.1 (recursive via spoke1-1 tunnel 11.1.1.11),
00:18:17
                                         (recursive via spoke1-2 tunnel 111.1.1.11),
00:18:17, [1/0]
B      33.0.0.0/8 [200/0] via 10.200.1.1 (recursive via spoke1-1 tunnel 11.1.1.11),
00:18:17
                                         (recursive via spoke1-2 tunnel 111.1.1.11),
00:18:17, [1/0]
B      33.1.1.0/24 [200/0] via 10.200.1.101 (recursive via spoke1-1_0 tunnel 13.1.1.3),
00:01:09
                                         (recursive via spoke1-2_0 tunnel
113.1.1.3), 00:01:09, [1/0]
```

The remote route learned from Spoke 2 through the spoke1-2_0 tunnel and using BGP is 33.1.1.0/24.

IPv6 use case

To trigger a second spoke-to-spoke shortcut VPN over IPv6, on host 2001:22::22/64, ping the host 2001:33::133/64 in the Engineering Department. Because of the SD-WAN rule, use SD-WAN member 2 (via ISP2) and its dynamic shortcuts to reach hosts in the Engineering Department.

To verify the status on Spoke 1:**1. Verify the BGP status:**

```
# get router info6 bgp summary
VRF 0 BGP router identifier 10.200.1.100, local AS number 65100
BGP table version is 7
1 BGP AS-PATH entries
0 BGP community entries
Neighbor      V      AS MsgRcvd MsgSent   TblVer  InQ  OutQ Up/Down  State/PfxRcd
```

```

2001::10:200:1:1    4      65100    264    265      4    0    0 00:18:18    3
2001::10:200:1:101 4      65100    19     19      6    0    0 00:01:11    1
Total number of neighbors 2

```

Spoke 1 continues to have its BGP neighbors:

- Hub FortiGate at 2001::10:200:1:1
- Spoke 2 FortiGate at 2001::10:200:1:101

2. Verify the BGP routing table:

```

# get router info6 routing-table bgp
Routing table for VRF=0
B      2001::11:11:11:11/128 [200/0] via 2001::10:200:1:1 (recursive via spoke1-1
tunnel ::11.1.1.11), 00:18:20
                                                    (recursive via spoke1-2
tunnel ::111.1.1.11), 00:18:20, [1024/0]
B      2001:22::/32 [200/0] via 2001::10:200:1:1 (recursive via spoke1-1 tunnel
::11.1.1.11), 00:18:20
                                                    (recursive via spoke1-2 tunnel
::111.1.1.11), 00:18:20, [1024/0]
B      2001:33::/32 [200/0] via 2001::10:200:1:1 (recursive via spoke1-1 tunnel
::11.1.1.11), 00:18:20
                                                    (recursive via spoke1-2 tunnel
::111.1.1.11), 00:18:20, [1024/0]
B      2001:33::/64 [200/0] via 2001::10:200:1:101 (recursive via spoke1-1_0 tunnel
::13.1.1.3), 00:01:14
                                                    (recursive via spoke1-2_0 tunnel
::113.1.1.3), 00:01:14, [1024/0]

```

The remote route learned from Spoke 2 through the spoke1-2_0 tunnel and using BGP is 2001:33::/64.

SD-WAN monitor on ADVPN shortcuts

SD-WAN monitors ADVPN shortcut link quality by dynamically creating link monitors for each ADVPN link. The dynamic link monitor on the spoke will use ICMP probes and the IP address of the gateway as the monitored server. These ICMP probes will not be counted as actual user traffic that keeps the spoke-to-spoke tunnel alive.

- When no shortcut is established:

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel-1): state(alive), packet-loss(0.000%) latency(0.038), jitter(0.006) sla_
map=0x3
Seq(2 tunnel-2): state(alive), packet-loss(0.000%) latency(0.035), jitter(0.004) sla_
map=0x3
```

- When one shortcut is established:

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel-1): state(alive), packet-loss(0.000%) latency(0.039), jitter(0.003) sla_
map=0x3
Seq(1 tunnel-1_0): state(alive), packet-loss(0.000%) latency(0.060), jitter(0.023) sla_
map=0x3
Seq(2 tunnel-2): state(alive), packet-loss(0.000%) latency(0.035), jitter(0.002) sla_
map=0x3
```

- When more than one shortcut is established:

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel-1): state(alive), packet-loss(0.000%) latency(0.036), jitter(0.004) sla_
map=0x3
Seq(1 tunnel-1_0): state(alive), packet-loss(0.000%) latency(0.041), jitter(0.009) sla_
map=0x3
Seq(2 tunnel-2): state(alive), packet-loss(0.000%) latency(0.030), jitter(0.005) sla_
map=0x3
Seq(2 tunnel-2_0): state(alive), packet-loss(0.000%) latency(0.031), jitter(0.004) sla_
map=0x3
```

Hold down time to support SD-WAN service strategies

In a hub and spoke SD-WAN topology with shortcuts created over ADVPN, a downed or recovered shortcut can affect which member is selected by an SD-WAN service strategy. When a downed shortcut tunnel recovers and the shortcut is added back into the service strategy, the shortcut is held at a low priority until the hold down time has elapsed.

By default, the hold down time is zero seconds. It can be set to 0 - 10000000 seconds.

To configure the hold down time:

```
config system sdwan
  config service
    edit 1
      set hold-down-time <integer>
    next
  end
end
```

Example

In this example, the hold down time is set to 15 seconds, and then the SD-WAN service is looked at before and after the hold down elapses after a downed shortcut recovers.

To configure the hold down time:

```
config system sdwan
  config service
    edit 1
      set hold-down-time 15
    next
  end
end
```

To view which SD-WAN member is selected before and after the hold down time elapses:

Before the hold down time has elapsed:

```
# diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(34), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(priority), link-cost-factor(packet-
  loss), link-cost-threshold(0), health-check(ping)
Hold down time(15) seconds, Hold start at 2003 second, now 2010

33.1.1.101-33.1.1.200\

```

Adaptive Forward Error Correction

Forward Error Correction (FEC) is used to control and correct errors in data transmission by sending redundant data across the VPN in anticipation of dropped packets occurring during transit. The mechanism sends out x number of redundant packets for every y number of base packets.

Adaptive FEC considers link conditions and dynamically adjusts the FEC packet ratio:

- The FEC base and redundant packet relationship is dynamically adjusted based on changes to the network SLA metrics defined in the SD-WAN SLA health checks. For example, when there is no or low packet loss in the network, FEC can work on a low redundant level sending only one redundant packet for every 10 base packets. As packet loss increases, the number of redundant packets sent can rise accordingly.
- FEC can be applied only to streams that are sensitive to packet loss. For Example, policies that allow the UDP based VoIP protocol can enable FEC, while TCP based traffic policies do not. This reduces unnecessary bandwidth consumption by FEC.
- Because FEC does not support NPU offloading, the ability to specify streams and policies that do not require FEC allows those traffic to be offloaded. This means that all traffic suffers a performance impact.

In this example, an IPsec tunnel is configured between two FortiGates that both have FEC enabled. The tunnel is an SD-WAN zone, and an SLA health-check is used to monitor the quality of the VPN overlay. The intention is to apply FEC to UDP traffic that is passing through the VPN overlay, while allowing all other traffic to pass through without FEC. An FEC profile is configured to adaptively increase redundant levels if the link quality exceeds a 10% packet loss threshold, or the bandwidth exceeds 950 Mbps.

The DMZ interface and IPsec tunnel vd1-p1 are SD-WAN members. FEC is enabled on vd1-p1, and health-check works on vd1-p1.

To configure the FortiGates:

1. On both FortiGates, enable FEC and NPU offloading on the IPsec tunnel vd1-p1:

```

config vpn ipsec phase1-interface
edit "vd1-p1"
set npu-offload enable

```

```
        set fec-egress enable
        set fec-ingress enable
    next
end
```

2. On FortiGate A, configure SD-WAN:

The VPN overlay member (vd1-p1) must be included in the health-check and configured as the higher priority member in the SD-WAN rule.

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 2
            set interface "vd1-p1"
        next
    end
    config health-check
        edit "1"
            set server "2.2.2.2"
            set members 2
            config sla
                edit 1
                    next
            end
        next
    end
    config service
        edit 1
            set name "1"
            set dst "all"
            set src "172.16.205.0"
            set priority-members 2 1
        next
    end
end
```

3. On FortiGate A, create a policy to specify performing FEC on UDP traffic, and a policy for other traffic:

```
config firewall policy
    edit 1
        set srcintf "port5"
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr "172.16.205.0"
        set dstaddr "all"
        set schedule "always"
        set service "ALL_UDP"
        set fec enable
    next
```

```

edit 2
    set srcintf "any"
    set dstintf "any"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set schedule "always"
    set service "ALL"
next
end

```

4. On FortiGate A, configure FEC mapping to bind network SLA metrics and FEC base and redundant packets:

```

config vpn ipsec fec
    edit "m1"
        config mappings
            edit 1
                set base 8
                set redundant 2
                set packet-loss-threshold 10
            next
            edit 2
                set base 9
                set redundant 3
                set bandwidth-up-threshold 950000
            next
        end
    next
end

```

The mappings are matched from top to bottom: packet loss greater than 10% with eight base and two redundant packets, and then uploading bandwidth greater than 950 Mbps with nine base and three redundant packets.

5. On FortiGate A, apply the FEC mappings on vd1-p1:

```

config vpn ipsec phase1-interface
    edit "vd1-p1"
        set fec-health-check "1"
        set fec-mapping-profile "m1"
        set fec-base 10
        set fec-redundant 1
    next
end

```

The FEC base and redundant values are used when the link quality has not exceeded the limits specified in the FEC profile mapping. If `fec-codec` is set to `xor` the base and redundant packet values will not be updated.

To verify the results:

1. Send TCP and UDP traffic from PC1 to PC2, then check the sessions on FortiGate A:

```

# diagnose sys session list

session info: proto=6 proto_state=01 duration=12 expire=3587 timeout=3600 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3

hook=pre dir=org act=noop 172.16.205.11:49052->10.1.100.22:5001(0.0.0.0:0)
hook=post dir=reply act=noop 10.1.100.22:5001->172.16.205.11:49052(0.0.0.0:0)
misc=0 policy_id=1 pol_uuid_idx=593 auth_info=0 chk_client_info=0 vd=0
serial=000210fa tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=2 sdwan_service_id=1
rpdb_link_id=ff000001 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x5040000
no_ofld_reason: non-npu-intf

```

Non-FEC protected TCP traffic is offloaded, while FEC protected UDP traffic is not offloaded

2. On FortiGate A, check the health-check result and the corresponding FEC base and redundant packets:

```

# diagnose sys sdwan health-check
Health Check(1):
Seq(2 vdl-p1): state(alive), packet-loss(0.000%) latency(0.168), jitter(0.021),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1

```

Because bandwidth-up is more than 950000kbps, base and redundant are set to 9 and 3:

```

# diagnose vpn tunnel fec vdl-p1
egress:
    enabled=1 base=9 redundant=3 codec=0 timeout=10(ms)
    encode=6621 encode_timeout=6621 encode_fail=0
    tx_data=6880 tx_parity=18601
ingress:
    enabled=1 timeout=50(ms)
    fasm_cnt=0 fasm_full=0
    ipsec_fec_chk_fail=0 complete=0
    rx_data=0 rx_parity=0

```

```
recover=0 recover_timeout=0 recover_fail=0
rx=0 rx_fail=0
```

3. Make packet loss more than 10%, then check the health-check result and the corresponding FEC base and redundant packets again:

```
# diagnose sys sdwan health-check
Health Check(1):
Seq(2 vd1-p1): state(alive), packet-loss(15.000%) latency(0.168), jitter(0.017),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x0
```

Because packet loss is more than 10%, entry one in FEC mapping is first matched, and base and redundant are set to 8 and 2:

```
# diagnose vpn tunnel fec vd1-p1
egress:
  enabled=1 base=8 redundant=2 codec=0 timeout=10(ms)
  encode=6670 encode_timeout=6670 encode_fail=0
  tx_data=6976 tx_parity=18748
ingress:
  enabled=1 timeout=50(ms)
  fasm_cnt=0 fasm_full=0
  ipsec_fec_chk_fail=0 complete=0
  rx_data=0 rx_parity=0
  recover=0 recover_timeout=0 recover_fail=0
  rx=0 rx_fail=0
```

Dual VPN tunnel wizard

This wizard is used to automatically set up multiple VPN tunnels to the same destination over multiple outgoing interfaces. This includes automatically configuring IPsec, routing, and firewall settings, avoiding cumbersome and error-prone configuration steps.

To create a new SD-WAN VPN interface using the tunnel wizard:

1. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
2. In the *Interface* drop-down, click *+VPN*. The *Create IPsec VPN for SD-WAN members* pane opens.

3. Enter the required information, then click *Next*.
4. Review the settings then click *Create*.
5. Click *Close* to return to the SD-WAN page.
The newly created VPN interface will be highlighted in the *Interface* drop-down list.
6. Select the VPN interface to add it as an SD-WAN member, then click *OK*.

Duplicate packets on other zone members

When duplication rules are used, packets are duplicated on other good links within the SD-WAN zone and de-duplicated on the destination FortiGate. Use *force* mode to force duplication on other links within the SD-WAN zone, or use *on-demand* mode to trigger duplication only when SLA fails on the selected member.

The duplication rule is configured in the CLI by using the `config duplication` command. The following options can be configured:

Parameter	Description
srcaddr	Source address or address group names.
dstaddr	Destination address or address group names.
srcaddr6	Source IPv6 address or IPv6 address group names.
dstaddr6	Destination IPv6 address or IPv6 address group names.
srcintf	Incoming (ingress) interfaces or zones.
dstintf	Outgoing (egress) interfaces or zones.
service	Service and service group names.
packet-duplication	Configure packet duplication method. <ul style="list-style-type: none"> • disable: Disable packet duplication (default). • force: Duplicate packets across all interface members of the SD-WAN zone. • on-demand: Duplicate packets across all interface members of the SD-WAN zone based on the link quality.
packet-de-duplication	Enable/disable discarding of packets that have been duplicated (default = disable).

The `duplication-max-num <integer>` option under `config system sdwan` is the maximum number of interface members that a packet is duplicated on in the SD-WAN zone (2 - 4, default = 2). If this value is set to 3, the original packet plus two more copies are created. If there are three member interfaces in the SD-WAN zone and the `duplication-max-num` is set to 2, the packet duplication follows the configuration order, so the packets are duplicated on the second member.

Example

The packet duplication feature works best in a spoke-spoke or hub-and-spoke topology. In this example, a hub-and-spoke ADVPN topology is used. Before shortcuts are established, Hub 1 forwards the duplicate packets from Spoke 1 to Spoke 2. Once shortcuts are established, Hub 1 is transparent, and duplicate packets are exchanged directly between the spokes.

To configure packet duplication between Spoke 1 and Spoke 2:

1. Configure Spoke 1:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "sdwanzone_v4"
        next
    end
    config members
        edit 1
            set interface "t1"
            set zone "sdwanzone_v4"
        next
        edit 4
            set interface "t21"
            set zone "sdwanzone_v4"
        next
        edit 2
            set interface "t2"
            set zone "sdwanzone_v4"
        next
    end
    config health-check
        edit "h1"
            set server "10.34.1.1"
            set interval 1000
            set failtime 10
            set members 1 2
            config sla
                edit 1
```

```

        set packetloss-threshold 40
    next
end
next
end
config duplication
    edit 1
        set srcaddr "all"
        set dstaddr "all"
        set srcintf "port1"
        set dstintf "sdwanzone_v4"
        set service "ALL"
        set packet-duplication force
        set packet-de-duplication enable
    next
end
end
end

```

2. Configure Spoke 2 with similar settings.

Duplicate packets based on SD-WAN rules

SD-WAN duplication rules can specify SD-WAN service rules to trigger packet duplication. This allows the duplication to occur based on an SD-WAN rule instead of the source, destination, and service parameters in the duplication rule.

1. Packets can be forced to duplicate to all members of the same SD-WAN zone. See [Duplicate packets on other zone members on page 920](#) for details.

For example, in Spoke 1 set `packet-duplication` to `force` so that when a client sends a packet to the server, it is duplicated to all members of the same zone as long as its health check is alive. If a members health check is dead, then the member is removed from the SD-WAN duplication zone.

2. Packets can be duplicated to other members of the SD-WAN zone on-demand only when the condition of the link is not good enough.

Set `packet-duplication` to `on-demand`. If `sla-match-service` is disabled, when all the SLAs of the member exceed threshold (`sla_map=0`), the packet is duplicated. But when the SLAs are within threshold (`sla_map!=0`), the packet is not duplicated.

If `sla-match-service` is enabled, then only the SLA health checks and targets used in the service rule need to exceed threshold in order to trigger packet duplication.

3. Packets can be duplicated to all members of the same SD-WAN zone when the traffic matches one or more regular SD-WAN service rules.

The following example shows the third type of packet duplication.

In this example, SD-WAN is configured with three members: vpn1, vpn2, and vpn3. Service rule 1 controls all traffic from 10.100.20.0/24 to 172.16.100.0/24 using member 1.

To send a duplicate of the traffic that matches service rule 1 using member 2, members 1 and 2 are added to the same SD-WAN zone, and a duplication rule is configured with service-id set to 1.

To send a duplicate of the traffic that matches service rule 1 using member 2:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "zone2"
        next
    end
    config members
        edit 1
            set interface "vpn1"
        next
        edit 2
            set interface "vpn2"
        next
        edit 3
            set interface "vpn3"
            set zone "zone2"
        next
    end
    config service
        edit 1
            set dst "172.16.100.0"
            set src "10.100.20.0"
            set priority-members 1
        next
```

```

end
config duplication
  edit 1
    set service-id 1
    set packet-duplication force
  next
end
end

```

Speed tests run from the hub to the spokes in dial-up IPsec tunnels

In a hub and spoke SD-WAN topology that uses dial-up VPN overlays, QoS can be applied on individual tunnels based on the measured bandwidth between the hub and spokes. The FortiGate can use the built in speed test to dynamically populate the egress bandwidth to individual dial-up tunnels from the hub.

SD-WAN members on a spoke can switch routes when the speed test is running from the hub to the spoke. The speed test results can be cached for reuse when a tunnel comes back after going down.

CLI commands

Allow upload speed tests to be run from the hub to spokes on demand for dial-up IPsec tunnel:

```

config system speed-test-schedule
  edit <interface>
    set dynamic-server {enable | disable}
  next
end

```

<interface>	The dial-up IPsec tunnel interface on the hub.
dynamic-server {enable disable}	Enable/disable the dynamic speed test server (default = disable).

To limit the maximum and minimum bandwidth used in the speed test, enable `set update-inbandwidth` and `set update-outbandwidth`. See [Scheduled interface speedtest](#) on [page 795](#) for more information.

```

config system global
  set speedtest-server {enable | disable}
end

```

speedtest-server {enable disable}	Enable/disable the speed test server on the spoke (default = disable). This setting must be enabled on spoke FortiGates. This enables iPerf in server mode, which listens on the default iPerf TCP port 5201.
-------------------------------------	---

Allow an SD-WAN member on the spoke to switch routes when it is on speed test from the hub to spokes:

```

config system sdwan
  set speedtest-bypass-routing {enable | disable}
config neighbor

```

```

        edit <bgp neighbor>
            set mode speedtest
        next
    end
end

```

speedtest-bypass-routing {enable disable}	Enable/disable bypass routing when doing a speed test on an SD-WAN member (default = disable).
set mode speedtest	Use the speed test to select the neighbor.

Manually run uploading speed test on the physical interfaces of each tunnel of an dial-up IPsec interface:

```
execute speed-test-dynamic <interface> <tunnel_name> <'y'/'n'> <max-out> <min-out>
```

<interface>	IPsec phase1 interface name.
<tunnel_name>	The tunnel name, or all for all tunnels.
<'y'/'n'>	Apply the result to the tunnels' shaper or not.
<max-out>	The maximum speed used in a speed test, in kbps.
<min-out>	The minimum speed used in a speed test, in kbps.

Manually run a non-blocking uploading speed test:

```
diagnose netlink interface speed-test-tunnel <interface> <tunnel_name>
```

Debug and test commands:

diagnose debug application speedtest <int>	Enable debug of the speed test module in the forticron daemon.
diagnose debug application speedtestd <int>	Enable debug of the speed test server daemon.
diagnose test application forticron 9	List the scheduled speed tests.
diagnose test application forticron 10	Show the cached speed test results.
diagnose test application forticron 11	Write the cached speed test results to disk.
diagnose test application forticron 12	Load the speed test results from disk.
diagnose test application forticron 99	Cancel all pending speed tests.

Example

In this example, the hub is configured as a VPN dial-up server and both of the spokes are connected to the hub. It is assumed that the VPN configuration is already done, with a dynamic gateway type and kernel device creation (`net-device`) disabled. Only one SD-WAN interface is used, so there is only one VPN overlay member in the SD-WAN zone. Multiple WAN interfaces and VPN overlays could be used.

The VPN interfaces and IP addresses are:

FortiGate	Interface	IP Address
FGT_A (Hub)	hub-phase1	10.10.100.254
FGT_B (Spoke)	spoke11-p1	10.10.100.2
FGT_D (Spoke)	spoke21-p1	10.10.100.3

A recurring speed test is configured that runs on the hub over the dial-up interfaces. The speed tests are performed over the underlay interface from the hub to the spoke. Each spoke is configured to operate as a speed test server and to allow the speed test to run on its underlay interface. The spokes establish BGP peering with the hub over the VPN interface, and advertises its loopback network to the hub. The specific configuration is only shown for FGT_B.

When the speed test is running, routing through the VPN overlay can be bypassed, and route maps are used to filter the routes that are advertised to peers. The spoke's route map does not advertise any routes to the peer, forcing the hub to use others paths to reach the spoke's network.

When no speed tests are running, the spoke's route map allows its network to be advertised on the hub.

When the speed test is complete, the measured egress bandwidth is dynamically applied to the VPN tunnel on the hub, and the result is cached for future use, in case the tunnel is disconnected and reconnected again.

To configure the hub FortiGate (FGT_A):

1. Configure a shaping profile:

```
config firewall shaping-profile
  edit "profile_1"
    config shaping-entries
      edit 1
        set class-id 2
```

```

        set priority low
        set guaranteed-bandwidth-percentage 10
        set maximum-bandwidth-percentage 10
    next
end
set default-class-id 2
next
end

```

Three classes are used in the profile for low, medium, and high priority traffic. Each class is assigned a guaranteed and maximum bandwidth as a percentage of the measured bandwidth from the speed test.

2. Use the shaping profile in the interface:

```

config system interface
    edit "hub-phasel"
        set egress-shaping-profile "profile_1"
    next
end

```

3. Configure a schedule to use for the speed tests:

```

config firewall schedule recurring
    edit "speedtest_recurring"
        set start 01:00
        set end 23:00
        set day monday tuesday wednesday thursday friday saturday
    next
end

```

4. Configure the speed test schedule:

```

config system speed-test-schedule
    edit "hub-phasel"
        set schedules "speedtest_recurring"
        set dynamic-server enable
    next
end

```

To configure the spoke FortiGates (FGT_B and FGT_D):

1. Enable the speed test daemon:

```

config system global
    set speedtest-server enable
end

```

2. Allow speed tests on the interface:

```

config system interface
    edit "port1"
        append allowaccess speed-test
    next
end

```

3. Configure SD-WAN with bypass routing enabled for speed tests on member *spoke11-p1*:

```

config system sdwan
    set speedtest-bypass-routing enable
    config members

```

```

        edit 1
            set interface "spoke11-p1"
        next
    end
    config neighbor
        edit "10.10.100.254"
            set member 1
            set mode speedtest
        next
    end
end
end

```

4. Configure BGP routing:

```

config router route-map
    edit "No_Speed-Test"
        config rule
            edit 1
                set action permit
            next
        end
    next
    edit "Start_Speed-Test"
        config rule
            edit 1
                set action deny
            next
        end
    next
end

config router bgp
    set as 65412
    config neighbor
        edit "10.10.100.254"
            set remote-as 65412
            set route-map-out "Start_Speed-Test"
            set route-map-out-preferable "No_Speed-Test"
        next
    end
    config network
        edit 1
            set prefix 2.2.2.2 255.255.255.255
        next
        edit 2
            set prefix 10.1.100.0 255.255.255.0
        next
    end
end
end

```

To manually run the speed test:

```

# execute speed-test-dynamic hub-phase1 all y 1000 100
Start testing the speed of each tunnel of hub-phase1
[6400d9] hub-phase1_0: physical_intf=port1, local_ip=172.16.200.1, server_ip=172.16.200.2
Wait for test 6400d9 to finish...
Speed-test result for test ID 6400d9:

```

```
Completed
measured upload bandwidth is 1002 kbps
measured time Sun Jun 20 15:56:34 2021
```

The tested out-bandwidth is more than the set maximum accepted value 1000. Will update the tunnel's shaper by the set update-outbandwidth-maximum.

Apply shaping profile 'profile_1' with bandwidth 1000 to tunnel hub-phase1_0 of interface hub-phase1

```
[6400e0] hub-phase1_1: physical_intf=port1, local_ip=172.16.200.1, server_ip=172.16.200.4
Wait for test 6400e0 to finish...
```

Speed-test result for test ID 6400e0:

```
Completed
measured upload bandwidth is 1002 kbps
measured time Sun Jun 20 15:56:39 2021
```

The tested out-bandwidth is more than the set maximum accepted value 1000. Will update the tunnel's shaper by the set update-outbandwidth-maximum.

Apply shaping profile 'profile_1' with bandwidth 1000 to tunnel hub-phase1_1 of interface hub-phase1

```
# diagnose netlink interface speed-test-tunnel hub-phase1 all
send speed test request for tunnel 'hub-phase1_0' of 'hub-phase1': 172.16.200.1 ->
172.16.200.2
send speed test request for tunnel 'hub-phase1_1' of 'hub-phase1': 172.16.200.1 ->
172.16.200.4
```

Results

1. Before the speed test starts, FGT_A can receive the route from FGT_B by BGP:

```
# get router info routing-table bgp
Routing table for VRF=0
B      2.2.2.2/32 [200/0] via 10.10.100.2 (recursive via 172.16.200.2, hub-phase1),
00:00:10
B      10.1.100.0/24 [200/0] via 10.10.100.2 (recursive via 172.16.200.2, hub-phase1),
00:00:10
```

2. At the scheduled time, the speed test starts for the hub-phase1 interface from hub to spoke:

```
# diagnose test application forticron 9
Speed test schedules:
  Interface      Server      Update      Up/Down-limit (kbps)      Days
H:M      TOS      Schedule
-----
14:41      0x00      hub-phase1      dynamic      11111111
14:41      0x00      speedtest_recurring
Active schedules:
  64002f: hub-phase1(port1) 172.16.200.2      hub-phase1_1
  64002e: hub-phase1(port1) 172.16.200.4      hub-phase1_0
```

The diagnose debug application speedtest -1 command can be used on both the hub and spokes to check the speed test execution.

3. While the speed test is running, FGT_A does not receive the route from FGT_B by BGP:

```
# get router info routing-table bgp
Routing table for VRF=0
```

4. Speed tests results can be dynamically applied to the dial-up tunnel for egress traffic shaping:

```
# diagnose vpn tunnel list
-----
name=hub-phase1_0 ver=2 serial=c 172.16.200.1:0->172.16.200.4:0 tun_id=172.16.200.4 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
    bandwidth=737210 (kbps) lock_hit=0 default_class=2 n_active_class=3
    class-id=2 allocated-bandwidth=73720 (kbps) guaranteed-
bandwidth=73720 (kbps)
    max-bandwidth=73720 (kbps) current-bandwidth=0 (kbps)
    priority=low forwarded_bytes=52
    dropped_packets=0 dropped_bytes=0
    class-id=3 allocated-bandwidth=221163 (kbps) guaranteed-
bandwidth=221162 (kbps)
    max-bandwidth=294883 (kbps) current-bandwidth=0 (kbps)
    priority=medium forwarded_bytes=0
    dropped_packets=0 dropped_bytes=0
    class-id=4 allocated-bandwidth=442325 (kbps) guaranteed-
bandwidth=147441 (kbps)
    max-bandwidth=442325 (kbps) current-bandwidth=0 (kbps)
    priority=high forwarded_bytes=0
    dropped_packets=0 dropped_bytes=0
-----
name=hub-phase1_1 ver=2 serial=d 172.16.200.1:0->172.16.200.2:0 tun_id=172.16.200.2 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
    bandwidth=726813 (kbps) lock_hit=0 default_class=2 n_active_class=3
    class-id=2 allocated-bandwidth=72681 (kbps) guaranteed-
bandwidth=72681 (kbps)
    max-bandwidth=72681 (kbps) current-bandwidth=0 (kbps)
    priority=low forwarded_bytes=123
    dropped_packets=0 dropped_bytes=0
    class-id=3 allocated-bandwidth=218044 (kbps) guaranteed-
bandwidth=218043 (kbps)
    max-bandwidth=290725 (kbps) current-bandwidth=0 (kbps)
    priority=medium forwarded_bytes=0
    dropped_packets=0 dropped_bytes=0
    class-id=4 allocated-bandwidth=436087 (kbps) guaranteed-
bandwidth=145362 (kbps)
    max-bandwidth=436087 (kbps) current-bandwidth=0 (kbps)
    priority=high forwarded_bytes=0
    dropped_packets=0 dropped_bytes=0
```

5. Speed test results can be cached, indexed, and written to disk:

```
# diagnose test application forticron 10
Speed test results:
1: vdom=root, phaselintf=hub-phase1, peer-id='spoke11-p1', bandwidth=737210, last_
log=1624226603
2: vdom=root, phaselintf=hub-phase1, peer-id='spoke21-p1', bandwidth=726813, last_
log=1624226614

# diagnose test application forticron 11
Write 2 logs to disk.
```

```
# diagnose test application forticron 12
load 2 results.
```

Disable then reenable the IPsec VPN tunnel and the cached speed test results can be applied to the tunnel again:

```
# diagnose vpn tunnel list
-----
name=hub-phase1_0 ver=2 serial=c 172.16.200.1:0->172.16.200.4:0 tun_id=172.16.200.4 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
    bandwidth=737210 (kbps) lock_hit=0 default_class=2 n_active_class=3
-----
name=hub-phase1_1 ver=2 serial=d 172.16.200.1:0->172.16.200.2:0 tun_id=172.16.200.2 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
    bandwidth=726813 (kbps) lock_hit=0 default_class=2 n_active_class=3
```

Interface based QoS on individual child tunnels based on speed test results

In a hub and spoke SD-WAN topology that uses dial-up VPN overlays, QoS can be applied on individual tunnels based on the measured bandwidth between the hub and spokes. The FortiGate can use the built in speed test to dynamically populate the egress bandwidth to individual dial-up tunnels from the hub.

A bandwidth limit, derived from the speed test, and a traffic shaping profile can be applied on the dial-up IPsec tunnel interface on the hub. A class ID and percentage based QoS settings can be applied to individual child tunnels using a traffic shaping policy and profile.

CLI commands

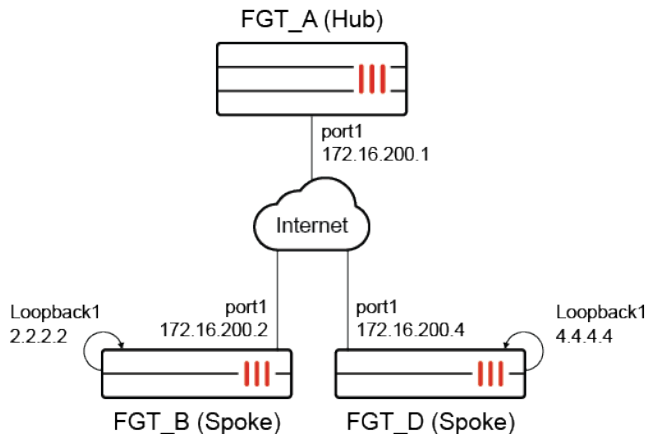

If the interface is an IPsec dial-up server, then egress shaping profile type can only be set to `policing`; it cannot be set to `queuing`:

```
config firewall shaping-profile
    edit <profile-name>
        set type policing
    next
end
```

The `outbandwidth` value is dynamically obtained from the speed test results for each individual child tunnel, and should not be set manually:

```
config system interface
    edit <dialup-server-phase1-name>
        set egress-shaping-profile <profile-name>
        set outbandwidth <bandwidth>
    next
end
```

Example

In this example, the hub is configured as a VPN dial-up server and both of the spokes are connected to the hub. It is assumed that the VPN configuration is already done, with a dynamic gateway type and kernel device creation (`net-device`) disabled. Only one SD-WAN interface is used, so there is only one VPN overlay member in the SD-WAN zone. Multiple WAN interfaces and VPN overlays could be used.

The VPN interfaces and IP addresses are:

FortiGate	Interface	IP Address
FGT_A (Hub)	hub-phase1	10.10.100.254
FGT_B (Spoke)	spoke11-p1	10.10.100.2
FGT_D (Spoke)	spoke21-p1	10.10.100.3

The hub VPN has two child tunnels, one to each spoke.

The speed test configuration is shown in [Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 925](#). This example shows applying a shaping profile to the hub's tunnel interface in order to apply interface based traffic shaping to the child tunnels.

A traffic shaping policy is used to match and assign traffic to the classes in the shaping profile.

To configure the hub FortiGate (FGT_A) and check the results:

1. Configure the hub FortiGate (FGT_A) as in [Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 925](#).
2. Configure the shaping profile:

```

config firewall shaping-profile
  edit "profile_1"
    config shaping-entries
      edit 1
        set class-id 2
        set priority low
        set guaranteed-bandwidth-percentage 10
        set maximum-bandwidth-percentage 10
      next
    next
  next

```

```

edit 2
    set class-id 3
    set priority medium
    set guaranteed-bandwidth-percentage 30
    set maximum-bandwidth-percentage 40
next
edit 3
    set class-id 4
    set priority high
    set guaranteed-bandwidth-percentage 20
    set maximum-bandwidth-percentage 60
next
end
set default-class-id 2
next
end

```

3. Configure a traffic shaping policy:

```

config firewall shaping-policy
    edit 2
        set service "ALL"
        set schedule "always"
        set dstintf "hub-phase1"
        set class-id 3
        set srcaddr "all"
        set dstaddr "all"
    next
end

```

In this example, all traffic through the hub-phase1 interface is put into class ID 3. Class IDs can be assigned based on your traffic requirements.

- At the scheduled time, the speed test will start for the hub-phase1 interface from the hub to the spokes. The speed test results can then be dynamically applied on individual child tunnels as egress traffic shaping, and the class ID percentage based QoS settings is applicable on them as templates.

```

# diagnose vpn tunnel list
-----
name=hub-phase1_0 ver=2 serial=c 172.16.200.1:0->172.16.200.4:0 tun_id=172.16.200.4 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
    bandwidth=737210 (kbps) lock_hit=0 default_class=2 n_active_class=3
    class-id=2 allocated-bandwidth=73720 (kbps) guaranteed-
bandwidth=73720 (kbps)
    max-bandwidth=73720 (kbps) current-bandwidth=0 (kbps)
    priority=low forwarded_bytes=52
    dropped_packets=0 dropped_bytes=0
    class-id=3 allocated-bandwidth=221163 (kbps) guaranteed-
bandwidth=221162 (kbps)
    max-bandwidth=294883 (kbps) current-bandwidth=0 (kbps)
    priority=medium forwarded_bytes=0
    dropped_packets=0 dropped_bytes=0
    class-id=4 allocated-bandwidth=442325 (kbps) guaranteed-
bandwidth=147441 (kbps)
    max-bandwidth=442325 (kbps) current-bandwidth=0 (kbps)

```

```

                priority=high    forwarded_bytes=0
                dropped_packets=0    dropped_bytes=0
-----
name=hub-phasel_1 ver=2 serial=d 172.16.200.1:0->172.16.200.2:0 tun_id=172.16.200.2 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
    bandwidth=726813 (kbps) lock_hit=0 default_class=2 n_active_class=3
    class-id=2    allocated-bandwidth=72681 (kbps)    guaranteed-
bandwidth=72681 (kbps)
    max-bandwidth=72681 (kbps)    current-bandwidth=0 (kbps)
    priority=low    forwarded_bytes=123
    dropped_packets=0    dropped_bytes=0
    class-id=3    allocated-bandwidth=218044 (kbps)    guaranteed-
bandwidth=218043 (kbps)
    max-bandwidth=290725 (kbps)    current-bandwidth=0 (kbps)
    priority=medium    forwarded_bytes=0
    dropped_packets=0    dropped_bytes=0
    class-id=4    allocated-bandwidth=436087 (kbps)    guaranteed-
bandwidth=145362 (kbps)
    max-bandwidth=436087 (kbps)    current-bandwidth=0 (kbps)
    priority=high    forwarded_bytes=0
    dropped_packets=0    dropped_bytes=0

```

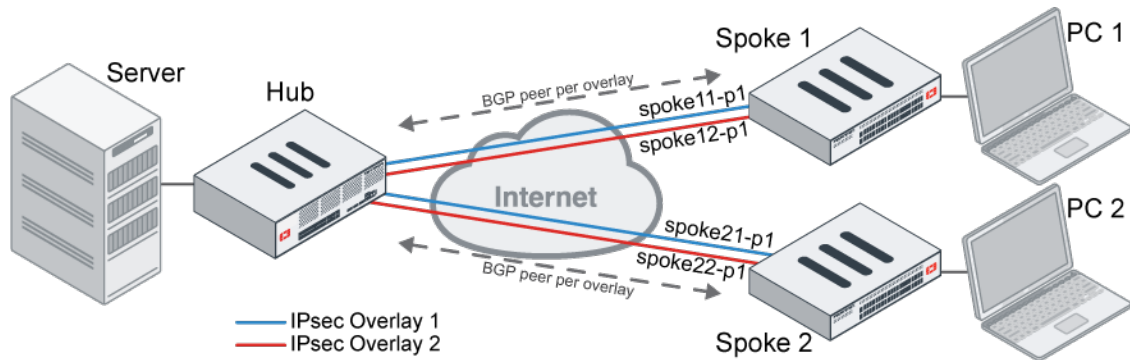

The guaranteed and maximum bandwidths equal 10% of the speed test result, as expected.

SD-WAN in large scale deployments

Phase 2 selectors can be used to inject IKE routes on the ADVPN shortcut tunnel. When configuration method (`mode-cfg`) is enabled in IPsec phase 1 configuration, enabling `mode-cfg-allow-client-selector` allows custom phase 2 selectors to be configured. By also enabling the addition of a route to the peer destination selector (`add-route`) in the phase 1 configuration, IKE routes based on the phase 2 selectors can be injected. This means that routes do not need to be reflected on the hub to propagate them between spokes, avoiding possible BGP daemon process load issues and improving network scalability in a large-scale ADVPN network.

Route map rules can apply priorities to BGP routes. On the hub, priorities can be set in a route map's rules, and the route map can be applied on BGP routes. This allows the hub to mark the preferred path learned from the spokes with a priority value (lower priority is preferred), instead of using multiple SD-WAN policy routes on the hub. When a preferred outbound route map (`route-map-out-preferable`) is also configured in an SD-WAN neighbor on the spoke, deploying SD-WAN rules on the hub to steer traffic from the hub to a spoke is unnecessary.

SD-WAN members' local cost can be exchanged on the ADVPN shortcut tunnel so that spokes can use the remote cost as tiebreak to select a preferred shortcut. If multiple shortcuts originate from the same member to different members on the same remote spoke, then the remote cost on the shortcuts is used as the tiebreak to decide which shortcut is preferred.

In this example, SD-WAN is configured on an ADVPN network with a BGP neighbor per overlay.

Instead of reflecting BGP routes with the route-reflector on the hub, when the shortcuts are triggered, IKE routes on the shortcuts are directly injected based on the configured phase 2 selectors to allow routes to be exchanged between spokes.

Routes between the hub and the spokes are exchanged by BGP, and the spokes use the default route to send spoke-to-spoke traffic to the hub and trigger the shortcuts.

Instead of configuring SD-WAN rules on the hub, different priorities are configured on the BGP routes by matching different BGP communities to steer traffic from the hub to the spokes.

To configure Spoke 1:

1. Configure phase 1:

```
config vpn ipsec phase1-interface
  edit "spoke11-p1"
    ...
    set ike-version 2
    set net-device enable
    set add-route enable
    set mode-cfg enable
    set auto-discovery-receiver enable
    set mode-cfg-allow-client-selector enable
    set link-cost 11
    ...
  next
  edit "spoke12-p1"
    ...
    set ike-version 2
    set net-device enable
    set add-route enable
    set mode-cfg enable
    set auto-discovery-receiver enable
    set mode-cfg-allow-client-selector enable
    set link-cost 21
    ...
  next
end
```

2. Configure phase 2:

```
config vpn ipsec phase2-interface
  edit "spoke11-p2"
```

```

        ...
        set src-name "LAN_Net"
        set dst-name "all"
    next
    edit "spoke12-p2"
        ...
        set src-name "LAN_Net"
        set dst-name "all"
    next
end

```

3. Configure an address group:

Spoke 1 uses LAN subnet 10.1-3.100.0/24.

```

config firewall addrgrp
    edit "LAN_Net"
        set member "10.1.100.0" "10.2.100.0" "10.3.100.0"
    next
end

```

4. Configure route maps:

- If overlay 1 to the hub is in SLA, attach "65000:1" to the BGP routes advertised to the hub over overlay 1.
- If overlay 2 to the hub is in SLA, attach "65000:2" to the BGP routes advertised to the hub over overlay 2.
- If any overlay to the hub is out of SLA, attach "65000:9999" to the BGP routes advertised to the hub over any overlay.

```

config router route-map
    edit "HUB_CARRIER1"
        config rule
            edit 1
                set set-community "65000:1"
            ...
        next
    end
    ...
next
edit "HUB_CARRIER2"
    config rule
        edit 1
            set set-community "65000:2"
        ...
    next
end
...
next
edit "HUB_BAD"
    config rule
        edit 1
            set set-community "65000:9999"
        ...
    next
end
...
next
end

```

5. Configure BGP and SD-WAN members and neighbors:

```
config router bgp
  set as 65412
  config neighbor
    edit "10.10.15.253"
      set remote-as 65412
      set route-map-out "HUB_BAD"
      set route-map-out-preferable "HUB_CARRIER1"
      ...
    next
    edit "10.10.16.253"
      set remote-as 65412
      set route-map-out "HUB_BAD"
      set route-map-out-preferable "HUB_CARRIER2"
      ...
    next
  end
end

config system sdwan
  config members
    edit 1
      set interface "spoke11-p1"
      set cost 10
    next
    edit 2
      set interface "spoke12-p1"
      set cost 20
    next
  end
  config neighbor
    edit "10.10.15.253"
      set member 1
      set health-check "1"
      set sla-id 1
    next
    edit "10.10.16.253"
      set member 2
      set health-check "11"
      set sla-id 1
    next
  end
end
```

To configure Spoke 2:

1. Configure phase 1:

```
config vpn ipsec phase1-interface
  edit "spoke21-p1"
    ...
    set ike-version 2
    set net-device enable
    set add-route enable
    set mode-cfg enable
    set auto-discovery-receiver enable
    set mode-cfg-allow-client-selector enable
    set link-cost 101
```

```

    ...
next
edit "spoke22-p1"
    ...
    set ike-version 2
    set net-device enable
    set add-route enable
    set mode-cfg enable
    set auto-discovery-receiver enable
    set mode-cfg-allow-client-selector enable
    set link-cost 201
next
end

```

2. Configure phase 2:

```

config vpn ipsec phase2-interface
edit "spoke21-p2"
    ...
    set src-name "LAN_Net"
    set dst-name "all"
next
edit "spoke22-p2"
    ...
    set src-name "LAN_Net"
    set dst-name "all"
next
end

```

3. Configure an address group:

Spoke 2 uses LAN subnet 192.168.5-7.0/24.

```

config firewall addrgrp
edit "LAN_Net"
    set member "192.168.5.0" "192.168.6.0" "192.168.7.0"
next
end

```

4. Configure route maps:

- If overlay 1 to the hub is in SLA, attach "65000:1" to the BGP routes advertised to the hub over overlay 1.
- If overlay 2 to the hub is in SLA, attach "65000:2" to the BGP routes advertised to the hub over overlay 2.
- If any overlay to the hub is out of SLA, attach "65000:9999" to the BGP routes advertised to the hub over any overlay.

```

config router route-map
edit "HUB_CARRIER1"
    config rule
    edit 1
        set set-community "65000:1"
        ...
    next
end
...
next
edit "HUB_CARRIER2"
    config rule
    edit 1

```

```

        set set-community "65000:2"
        ...
    next
end
...
next
edit "HUB_BAD"
config rule
    edit 1
        set set-community "65000:9999"
        ...
    next
end
...
next
end

```

5. Configure BGP and SD-WAN members and neighbors:

```

config router bgp
    set as 65412
    config neighbor
        edit "10.10.15.253"
            set remote-as 65412
            set route-map-out "HUB_BAD"
            set route-map-out-preferable "HUB_CARRIER1"
            ...
        next
        edit "10.10.16.253"
            set remote-as 65412
            set route-map-out "HUB_BAD"
            set route-map-out-preferable "HUB_CARRIER2"
            ...
        next
    end
end

config system sdwan
    config members
        edit 1
            set interface "spoke21-p1"
            set cost 10
        next
        edit 2
            set interface "spoke22-p1"
            set cost 20
        next
    end
    config neighbor
        edit "10.10.15.253"
            set member 1
            set health-check "1"
            set sla-id 1
        next
        edit "10.10.16.253"
            set member 2
            set health-check "11"
        next
    end
end

```

```

        set sla-id 1
    next
end
end

```

To configure the hub:

1. Configure the route maps:

- Set the priority to 100 for routes with community 65000:1, indicating that they are in SLA for overlay 1.
- Set the priority to 200 for routes with community 65000:2, indicating that they are in SLA for overlay 2.
- Set the priority to 9999 for routes with community 65000:9999, indicating that they are out of SLA for any overlay.

```

config router route-map
    edit "Set_Pri"
        config rule
            edit 1
                set match-community "comm_65000:1"
                set set-priority 100
            next
            edit 2
                set match-community "comm_65000:2"
                set set-priority 200
            next
            edit 3
                set match-community "comm_65000:9999"
                set set-priority 9999
            next
        end
    next
end

```

2. Configure BGP:

```

config router bgp
    set as 65412
    config neighbor-group
        edit "advpn"
            set remote-as 65412
            set route-map-in "Set_Pri"
            ...
        next
        edit "advpn2"
            set remote-as 65412
            set route-map-in "Set_Pri"
            ...
        next
    end
    config neighbor-range
        edit 1
            set prefix 10.10.15.0 255.255.255.0
            set neighbor-group "advpn"
        next
        edit 2
            set prefix 10.10.16.0 255.255.255.0
            set neighbor-group "advpn2"
        next
    end

```

```

        next
    end
end

```

To test the configuration:

1. Check the routing tables on the spokes:

Spoke 1:

```

spoke-1 (root) # get router info routing-table all
B*      0.0.0.0/0 [200/0] via 10.10.15.253 (recursive is directly connected, spoke11-
p1), 00:01:17, [1/0]          // default route to hub
                        [200/0] via 10.10.16.253 (recursive is directly connected,
spoke12-p1), 00:01:17, [1/0]
B      9.0.0.0/24 [200/0] via 10.10.15.253 (recursive is directly connected, spoke11-
p1), 00:01:17, [1/0]          // route to the server behind hub
                        [200/0] via 10.10.16.253 (recursive is directly connected,
spoke12-p1), 00:01:17, [1/0]
C      10.1.100.0/24 is directly connected, port2          // route to PC 1
C      10.10.15.0/24 is directly connected, spoke11-p1     // overlay 1
C      10.10.15.1/32 is directly connected, spoke11-p1
C      10.10.16.0/24 is directly connected, spoke12-p1     // overlay 2
C      10.10.16.1/32 is directly connected, spoke12-p1

```

Spoke 2:

```

spoke-2 (root) # get router info routing-table all
B*      0.0.0.0/0 [200/0] via 10.10.15.253 (recursive is directly connected, spoke21-
p1), 00:46:14, [1/0]          // default route to hub
                        [200/0] via 10.10.16.253 (recursive is directly connected,
spoke22-p1), 00:46:14, [1/0]
B      9.0.0.0/24 [200/0] via 10.10.15.253 (recursive is directly connected, spoke21-
p1), 00:46:18, [1/0]          // route to the server behind hub
                        [200/0] via 10.10.16.253 (recursive is directly connected,
spoke22-p1), 00:46:18, [1/0]
C      10.10.15.0/24 is directly connected, spoke21-p1     // overlay 1
C      10.10.15.2/32 is directly connected, spoke21-p1
C      10.10.16.0/24 is directly connected, spoke22-p1     // overlay 2
C      10.10.16.2/32 is directly connected, spoke22-p1
C      192.168.5.0/24 is directly connected, port2        // route to PC 2

```

2. Send traffic from PC 1 to PC 2 and trigger the shortcut:

The IKE routes on the shortcut are directly injected based on the phase 2 selectors, and spoke-to-spoke traffic then goes directly through the shortcut instead of going through the hub.

Spoke 1:

```

spoke-1 (root) # get router info routing-table static
S      192.168.5.0/24 [15/0] via spoke11-p1_0 tunnel 172.16.200.4 vrf 0, [1/0]
S      192.168.6.0/24 [15/0] via spoke11-p1_0 tunnel 172.16.200.4 vrf 0, [1/0]
S      192.168.7.0/24 [15/0] via spoke11-p1_0 tunnel 172.16.200.4 vrf 0, [1/0]

spoke-1 (root) # diagnose sniffer packet any 'host 192.168.5.44' 4
interfaces=[any]
filters=[host 192.168.5.44]
1.446306 port2 in 10.1.100.22 -> 192.168.5.44: icmp: echo request
1.446327 spoke11-p1_0 out 10.1.100.22 -> 192.168.5.44: icmp: echo request

```

```
1.446521 spoke11-p1_0 in 192.168.5.44 -> 10.1.100.22: icmp: echo reply
1.446536 port2 out 192.168.5.44 -> 10.1.100.22: icmp: echo reply
```

Spoke 2:

```
spoke-2 (root) # get router info routing-table static
S      10.1.100.0/24 [15/0] via spoke21-p1_0 tunnel 10.10.15.1 vrf 0, [1/0]
S      10.2.100.0/24 [15/0] via spoke21-p1_0 tunnel 10.10.15.1 vrf 0, [1/0]
S      10.3.100.0/24 [15/0] via spoke21-p1_0 tunnel 10.10.15.1 vrf 0, [1/0]
```

3. Confirm that the overlays are in SLA on the spokes:

Spoke 1:

```
spoke-1 (root) # diagnose sys sdwan neighbor
Neighbor(10.10.15.253): member(1)role(standalone)
Health-check(1:1) sla-pass selected alive
Neighbor(10.10.16.253): member(2)role(standalone)
Health-check(11:1) sla-pass selected alive
```

Spoke 2:

```
spoke-2 (root) # diagnose sys sdwan neighbor
Neighbor(10.10.15.253): member(1)role(standalone)
Health-check(1:1) sla-pass selected alive
Neighbor(10.10.16.253): member(2)role(standalone)
Health-check(11:1) sla-pass selected alive
```

4. On the hub, check that the routes received from the spokes have the expected priorities:

```
hub (root) # diagnose ip route list | grep proto=11
tab=254 vf=0 scope=0 type=1 proto=11 prio=100 0.0.0.0/0.0.0.0/0->10.1.100.0/24
pref=0.0.0.0 gwy=10.10.15.1 dev=101(hub-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=200 0.0.0.0/0.0.0.0/0->10.1.100.0/24
pref=0.0.0.0 gwy=10.10.16.1 dev=102(hub2-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=100 0.0.0.0/0.0.0.0/0->192.168.5.0/24
pref=0.0.0.0 gwy=10.10.15.2 dev=101(hub-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=200 0.0.0.0/0.0.0.0/0->192.168.5.0/24
pref=0.0.0.0 gwy=10.10.16.2 dev=102(hub2-phase1)
```

The priority set by the hub's route map is based on the community string received from the spoke. The route with a lower priority value is selected, so traffic to Spoke 1 goes out on the hub-phase1 tunnel:

```
hub (root) # diagnose sniffer packet any 'host 9.0.0.2' 4
interfaces=[any]
filters=[host 9.0.0.2]
2.735456 R190 in 9.0.0.2 -> 10.1.100.22: icmp: echo request
2.735508 hub-phase1 out 9.0.0.2 -> 10.1.100.22: icmp: echo request
2.735813 hub-phase1 in 10.1.100.22 -> 9.0.0.2: icmp: echo reply
2.735854 R190 out 10.1.100.22 -> 9.0.0.2: icmp: echo reply
```

5. If overlay 1 goes out of SLA, the priorities of the routes on the hub are updated and traffic from the hub to Spoke 1 goes through overlay 2:

Spoke 1:

```
spoke-1 (root) # diagnose sys sdwan neighbor
Neighbor(10.10.15.253): member(1)role(standalone)
Health-check(1:1) sla-fail alive
Neighbor(10.10.16.253): member(2)role(standalone)
Health-check(11:1) sla-pass selected alive
```

Spoke 2:

```
spoke-2 (root) # diagnose sys sdwan neighbor
Neighbor(10.10.15.253): member(1)role(standalone)
    Health-check(1:1)    sla-fail alive
Neighbor(10.10.16.253): member(2)role(standalone)
    Health-check(11:1)   sla-pass selected alive
```

Hub:

```
hub (root) # diagnose ip route list | grep proto=11
tab=254 vf=0 scope=0 type=1 proto=11 prio=200 0.0.0.0/0.0.0.0/0->10.1.100.0/24
pref=0.0.0.0 gwy=10.10.16.1 dev=102(hub2-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=9999 0.0.0.0/0.0.0.0/0->10.1.100.0/24
pref=0.0.0.0 gwy=10.10.15.1 dev=101(hub-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=200 0.0.0.0/0.0.0.0/0->192.168.5.0/24
pref=0.0.0.0 gwy=10.10.16.2 dev=102(hub2-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=9999 0.0.0.0/0.0.0.0/0->192.168.5.0/24
pref=0.0.0.0 gwy=10.10.15.2 dev=101(hub-phase1)

hub (root) # diagnose sniffer packet any 'host 9.0.0.2' 4
interfaces=[any]
filters=[host 9.0.0.2]
3.550181 R190 in 9.0.0.2 -> 10.1.100.22: icmp: echo request
3.550234 hub2-phase1 out 9.0.0.2 -> 10.1.100.22: icmp: echo request
3.550713 hub2-phase1 in 10.1.100.22 -> 9.0.0.2: icmp: echo reply
3.550735 R190 out 10.1.100.22 -> 9.0.0.2: icmp: echo reply
```

6. Verify the service diagnostics on Spoke 1:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Tie break: cfg
  Gen(4), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(2):
    1: Seq_num(1 spoke11-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(10),
    selected
    2: Seq_num(2 spoke12-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(20),
    selected
  Src address(1):
    10.1.100.0-10.1.100.255

  Dst address(1):
    0.0.0.0-255.255.255.255
```

7. Verify the service diagnostics on Spoke 2:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Tie break: cfg
  Gen(2), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(2):
    1: Seq_num(1 spoke21-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(10),
    selected
    2: Seq_num(2 spoke22-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(20),
    selected
  Src address(1):
```

```
192.168.5.0-192.168.5.255
```

```
Dst address(1):
0.0.0.0-255.255.255.255
```

8. Trigger shortcuts between Spoke 1 and Spoke 2:

- Shortcuts spoke11-p1_1 and spoke11-p1_0 originate from spoke11-p1.
- spoke11-p1_1 corresponds to spoke21-p1_0 on Spoke 2.
- spoke11-p1_0 corresponds to spoke22-p1_0 on Spoke 2.

Spoke 1:

```
# diagnose sys sdwan service
```

```
Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Tie break: cfg
Gen(11), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Member sub interface(4):
  3: seq_num(1), interface(spoke11-p1):
    1: spoke11-p1_0(80)
    2: spoke11-p1_1(81)
Members(4):
  1: Seq_num(1 spoke11-p1_1), alive, sla(0x1), gid(0), remote cost(101), cfg_order(0),
local cost(10), selected
  2: Seq_num(1 spoke11-p1_0), alive, sla(0x1), gid(0), remote cost(201), cfg_order(0),
local cost(10), selected
  3: Seq_num(1 spoke11-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(10),
selected
  4: Seq_num(2 spoke12-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(20),
selected
Src address(1):
10.1.100.0-10.1.100.255

Dst address(1):
0.0.0.0-255.255.255.255
```

Spoke 2:

```
# diagnose sys sdwan service
```

```
Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Tie break: cfg
Gen(15), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Member sub interface(4):
  2: seq_num(1), interface(spoke21-p1):
    1: spoke21-p1_0(75)
  4: seq_num(2), interface(spoke22-p1):
    1: spoke22-p1_0(74)
Members(4):
  1: Seq_num(1 spoke21-p1_0), alive, sla(0x1), gid(0), remote cost(11), cfg_order(0),
local cost(10), selected
  2: Seq_num(1 spoke21-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(10),
selected
  3: Seq_num(2 spoke22-p1_0), alive, sla(0x1), gid(0), remote cost(11), cfg_order(1),
local cost(20), selected
  4: Seq_num(2 spoke22-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(20),
selected
```

```
Src address(1):
    192.168.5.0-192.168.5.255
```

```
Dst address(1):
    0.0.0.0-255.255.255.255
```

The spoke11-p1_1 shortcut on Spoke 1 is preferred over spoke11-p1_0 due to the lower remote link cost of 101 when they have the same local SD-WAN member cost of 10.

9. Verify the policy route list on Spoke 1:

```
# diagnose firewall proute list
list route policy info(vf=root):

id=2131755009(0x7f100001) vwl_service=1(1) vwl_mbr_seq=1 1 1 2 dscp_tag=0xfc 0xfc
flags=0x0 tos=0x00 tos_mask=0x00 protocol=0 sport=0-65535 iif=0(any) dport=1-65535 path
(4) oif=81(spoke11-p1_1) oif=80(spoke11-p1_0) oif=54(spoke11-p1) oif=55(spoke12-p1)
source(1): 10.1.100.0-10.1.100.255
destination(1): 0.0.0.0-255.255.255.255
hit_count=176 last_used=2022-07-12 11:56:08
```

Keeping sessions in established ADVPN shortcuts while they remain in SLA

In an SD-WAN hub and spoke configuration where ADVPN is used, when a primary shortcut goes out of SLA, traffic switches to the backup shortcut. During idle timeout, sessions will prefer using the primary parent tunnel and try to establish a new primary shortcut. However, because it is out of SLA, traffic switches back to the backup shortcut, which causes unnecessary traffic interruption.

The `sla-stickiness` option keeps existing sessions on the established ADVPN shortcuts while they remain in SLA instead of switching to a new link every idle timeout. New sessions will be routed through the primary shortcut if it is in SLA.

```
config system sdwan
    config service
        edit <id>
            set mode sla
            set sla-stickiness {enable | disable}
        next
    end
end
```

The `sla-stickiness` option can be applied in the following use cases.

Use case 1:

1. The sessions will switch over to the backup shortcut due to the primary shortcut being out of SLA.
2. After an idle timeout, the primary shortcut is torn down, and the routes will be reinstalled on the primary parent tunnel.
3. When `sla-stickiness` is enabled, even though the primary parent tunnel is preferred, established ADVPN sessions will remain on the backup shortcut (stickiness) instead of switching to the primary parent tunnel.
4. New sessions will be routed to the primary parent tunnel and trigger the primary shortcut, then traffic switches to the primary shortcut if it is in SLA.

Use case 2:

1. The sessions will switch over to the backup shortcut due to the primary shortcut being out of SLA.
2. After some time, the primary shortcut becomes in SLA.
3. When `sla-stickiness` is enabled, even though primary shortcut is preferred, established ADVPN sessions will remain on the backup shortcut (stickiness) instead of switching to the primary shortcut.
4. New sessions will be routed through the primary shortcut.

Example configuration

The following example demonstrates using the `sla-stickiness` option in use case 1.

After an idle timeout occurs, existing sessions remain on the spoke12-p1_0 backup shortcut tunnel. New sessions will try to create a shortcut over spoke11-p1, but will fall back to spoke12-p1_0 when it detects spoke11-p1 is out of SLA.

To configure shortcut stickiness for ADVPN shortcuts:

1. Configure SD-WAN on the Spoke_1 FortiGate:

```
config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
  end
  config members
    edit 1
      set interface "spoke11-p1"
    next
    edit 2
      set interface "spoke12-p1"
    next
  end
  config health-check
    edit "1"
      set server "9.0.0.1"
```

```

        set members 1 2
        config sla
            edit 1
            next
        end
    next
end
config service
    edit 1
        set name "1"
        set mode sla
        set sla-stickness enable
        set dst "all"
        set src "10.1.100.0"
        config sla
            edit "1"
                set id 1
            next
        end
        set priority-members 1 2
    next
end
end

```

2. Verify the SD-WAN configuration.

a. Verify the health check status:

```

# diagnose sys sdwan health-check
Health Check(1):
Seq(1 spoke11-p1): state(alive), packet-loss(0.000%) latency(0.368), jitter(0.051),
mos(4.404), bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_
map=0x1
Seq(2 spoke12-p1): state(alive), packet-loss(0.000%) latency(0.211), jitter(0.019),
mos(4.404), bandwidth-up(999999), bandwidth-dw(999979), bandwidth-bi(1999978) sla_
map=0x1

```

b. Verify the service status:

```

# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x2200 use-shortcut-sla sla-stickness
Tie break: cfg
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Members(2):
    1: Seq_num(1 spoke11-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
    selected
    2: Seq_num(2 spoke12-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
    selected
Src address(1):
    10.1.100.0-10.1.100.255

Dst address(1):
    0.0.0.0-255.255.255.255

```

The SD-WAN service rule prefers the primary parent tunnel (spoke11-p1) over the backup parent tunnel (spoke12-p1) before shortcuts are established.

3. Send traffic from PC-1 to PC-2 to trigger the primary shortcut. Verify the diagnostics.

a. Run a sniffer trace:

```
# diagnose sniffer packet any 'host 192.168.5.44' 4
interfaces=[any]
filters=[host 192.168.5.44]
14.878761 port2 in 10.1.100.22 -> 192.168.5.44: icmp: echo request
14.878905 spoke11-p1 out 10.1.100.22 -> 192.168.5.44: icmp: echo request
14.879842 spoke11-p1 in 192.168.5.44 -> 10.1.100.22: icmp: echo reply
14.880082 port2 out 192.168.5.44 -> 10.1.100.22: icmp: echo reply
15.879761 port2 in 10.1.100.22 -> 192.168.5.44: icmp: echo request
15.879882 spoke11-p1_0 out 10.1.100.22 -> 192.168.5.44: icmp: echo request
15.880433 spoke11-p1_0 in 192.168.5.44 -> 10.1.100.22: icmp: echo reply
15.880496 port2 out 192.168.5.44 -> 10.1.100.22: icmp: echo reply
```

The SD-WAN service rule sends traffic to the parent tunnel (spoke11-p1) initially, and then switches to the primary shortcut tunnel (spoke11-p1_0) once it is established.

b. Verify the service status:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x2200 use-shortcut-sla sla-stickiness
Tie break: cfg
Gen(2), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Member sub interface(3):
  2: seq_num(1), interface(spoke11-p1):
    1: spoke11-p1_0(57)
Members(3):
  1: Seq_num(1 spoke11-p1_0), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  2: Seq_num(1 spoke11-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  3: Seq_num(2 spoke12-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
Src address(1):
  10.1.100.0-10.1.100.255

Dst address(1):
  0.0.0.0-255.255.255.255
```

The SD-WAN service rule prefers the primary shortcut tunnel (spoke11-p1_0) over other tunnels.

4. Make the primary shortcut be out of SLA. The traffic will switch to the backup parent tunnel and trigger the backup shortcut. Verify the diagnostics.

a. Run a sniffer trace:

```
# diagnose sniffer packet any 'host 192.168.5.44' 4
interfaces=[any]
filters=[host 192.168.5.44]
20.588046 port2 in 10.1.100.22 -> 192.168.5.44: icmp: echo request
20.588157 spoke12-p1 out 10.1.100.22 -> 192.168.5.44: icmp: echo request
20.588791 spoke12-p1 in 192.168.5.44 -> 10.1.100.22: icmp: echo reply
20.588876 port2 out 192.168.5.44 -> 10.1.100.22: icmp: echo reply
21.589079 port2 in 10.1.100.22 -> 192.168.5.44: icmp: echo request
21.589190 spoke12-p1_0 out 10.1.100.22 -> 192.168.5.44: icmp: echo request
21.589661 spoke12-p1_0 in 192.168.5.44 -> 10.1.100.22: icmp: echo reply
21.589733 port2 out 192.168.5.44 -> 10.1.100.22: icmp: echo reply
```

When the primary shortcut tunnel goes out of SLA (spoke11-p1_0, alive, sla(0x0)), traffic reroutes to the backup parent tunnel (spoke12-p1) and then to the backup shortcut tunnel (spoke12-p1_0) once established.

b. Verify the service status:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x2200 use-shortcut-sla sla-stickiness
Tie break: cfg
Gen(23), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Member sub interface(4):
  1: seq_num(1), interface(spoke11-p1):
    1: spoke11-p1_0(62)
  3: seq_num(2), interface(spoke12-p1):
    1: spoke12-p1_0(63)
Members(4):
  1: Seq_num(1 spoke11-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  2: Seq_num(2 spoke12-p1_0), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
  3: Seq_num(2 spoke12-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
  4: Seq_num(1 spoke11-p1_0), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected
Src address(1):
  10.1.100.0-10.1.100.255

Dst address(1):
  0.0.0.0-255.255.255.255
```

The backup shortcut tunnel (spoke12-p1_0) is now preferred.

5. After an idle timeout, the primary shortcut is torn down. The primary parent tunnel is now preferred, but traffic is still kept on the backup shortcut due to sla-stickiness being enabled. Verify the diagnostics.

a. Verify the service status:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x2200 use-shortcut-sla sla-stickiness
Tie break: cfg
Gen(24), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Member sub interface(3):
  3: seq_num(2), interface(spoke12-p1):
    1: spoke12-p1_0(63)
Members(3):
  1: Seq_num(1 spoke11-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  2: Seq_num(2 spoke12-p1_0), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
  3: Seq_num(2 spoke12-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
Src address(1):
  10.1.100.0-10.1.100.255

Dst address(1):
  0.0.0.0-255.255.255.255
```

b. Run a sniffer trace:

```
# diagnose sniffer packet any 'host 192.168.5.44' 4
interfaces=[any]
filters=[host 192.168.5.44]
1.065143 port2 in 10.1.100.22 -> 192.168.5.44: icmp: echo request
1.065218 spoke12-p1_0 out 10.1.100.22 -> 192.168.5.44: icmp: echo request
1.065471 spoke12-p1_0 in 192.168.5.44 -> 10.1.100.22: icmp: echo reply
1.065508 port2 out 192.168.5.44 -> 10.1.100.22: icmp: echo reply
2.066155 port2 in 10.1.100.22 -> 192.168.5.44: icmp: echo request
2.066198 spoke12-p1_0 out 10.1.100.22 -> 192.168.5.44: icmp: echo request
2.066442 spoke12-p1_0 in 192.168.5.44 -> 10.1.100.22: icmp: echo reply
2.066480 port2 out 192.168.5.44 -> 10.1.100.22: icmp: echo reply
3.067201 port2 in 10.1.100.22 -> 192.168.5.44: icmp: echo request
3.067255 spoke12-p1_0 out 10.1.100.22 -> 192.168.5.44: icmp: echo request
3.067507 spoke12-p1_0 in 192.168.5.44 -> 10.1.100.22: icmp: echo reply
3.067544 port2 out 192.168.5.44 -> 10.1.100.22: icmp: echo reply
```

6. Send new traffic from PC1 to PC2. The traffic is routed to the primary parent tunnel and triggers the primary shortcut, then traffic will switch to the primary shortcut if it is in SLA. Verify the connection.

a. Run a sniffer trace:

```
# diagnose sniffer packet any 'host 192.168.5.4' 4
interfaces=[any]
filters=[host 192.168.5.4]
17.120310 port2 in 10.1.100.22 -> 192.168.5.4: icmp: echo request
17.120475 spoke11-p1 out 10.1.100.22 -> 192.168.5.4: icmp: echo request
17.121096 spoke11-p1 in 192.168.5.4 -> 10.1.100.22: icmp: echo reply
17.121151 port2 out 192.168.5.4 -> 10.1.100.22: icmp: echo reply
18.121331 port2 in 10.1.100.22 -> 192.168.5.4: icmp: echo request
18.121480 spoke11-p1_0 out 10.1.100.22 -> 192.168.5.4: icmp: echo request
18.121954 spoke11-p1_0 in 192.168.5.4 -> 10.1.100.22: icmp: echo reply
18.122007 port2 out 192.168.5.4 -> 10.1.100.22: icmp: echo reply
...
```

At first, traffic tries to go to the primary parent tunnel so that it can trigger the primary shortcut to establish. The primary shortcut (spoke11-p1_0) is in SLA and new traffic flows through it.

```
...
14.194066 port2 in 10.1.100.22 -> 192.168.5.4: icmp: echo request
14.194247 spoke12-p1_0 out 10.1.100.22 -> 192.168.5.4: icmp: echo request
14.194499 spoke12-p1_0 in 192.168.5.4 -> 10.1.100.22: icmp: echo reply
14.194565 port2 out 192.168.5.4 -> 10.1.100.22: icmp: echo reply
15.195093 port2 in 10.1.100.22 -> 192.168.5.4: icmp: echo request
15.195174 spoke12-p1_0 out 10.1.100.22 -> 192.168.5.4: icmp: echo request
15.195326 spoke12-p1_0 in 192.168.5.4 -> 10.1.100.22: icmp: echo reply
15.195361 port2 out 192.168.5.4 -> 10.1.100.22: icmp: echo reply
```

After the primary shortcut goes out of SLA, the traffic switches to the backup shortcut (spoke12-p1_0).

b. Verify the service status:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x2200 use-shortcut-sla sla-stickiness
Tie break: cfg
Gen(36), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Member sub interface(4):
  1: seq_num(1), interface(spoke11-p1):
    1: spoke11-p1_0(67)
```

```
3: seq_num(2), interface(spoke12-p1):
  1: spoke12-p1_0(66)
Members(4):
  1: Seq_num(1 spoke11-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  2: Seq_num(2 spoke12-p1_0), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
  3: Seq_num(2 spoke12-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
  4: Seq_num(1 spoke11-p1_0), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected
Src address(1):
  10.1.100.0-10.1.100.255

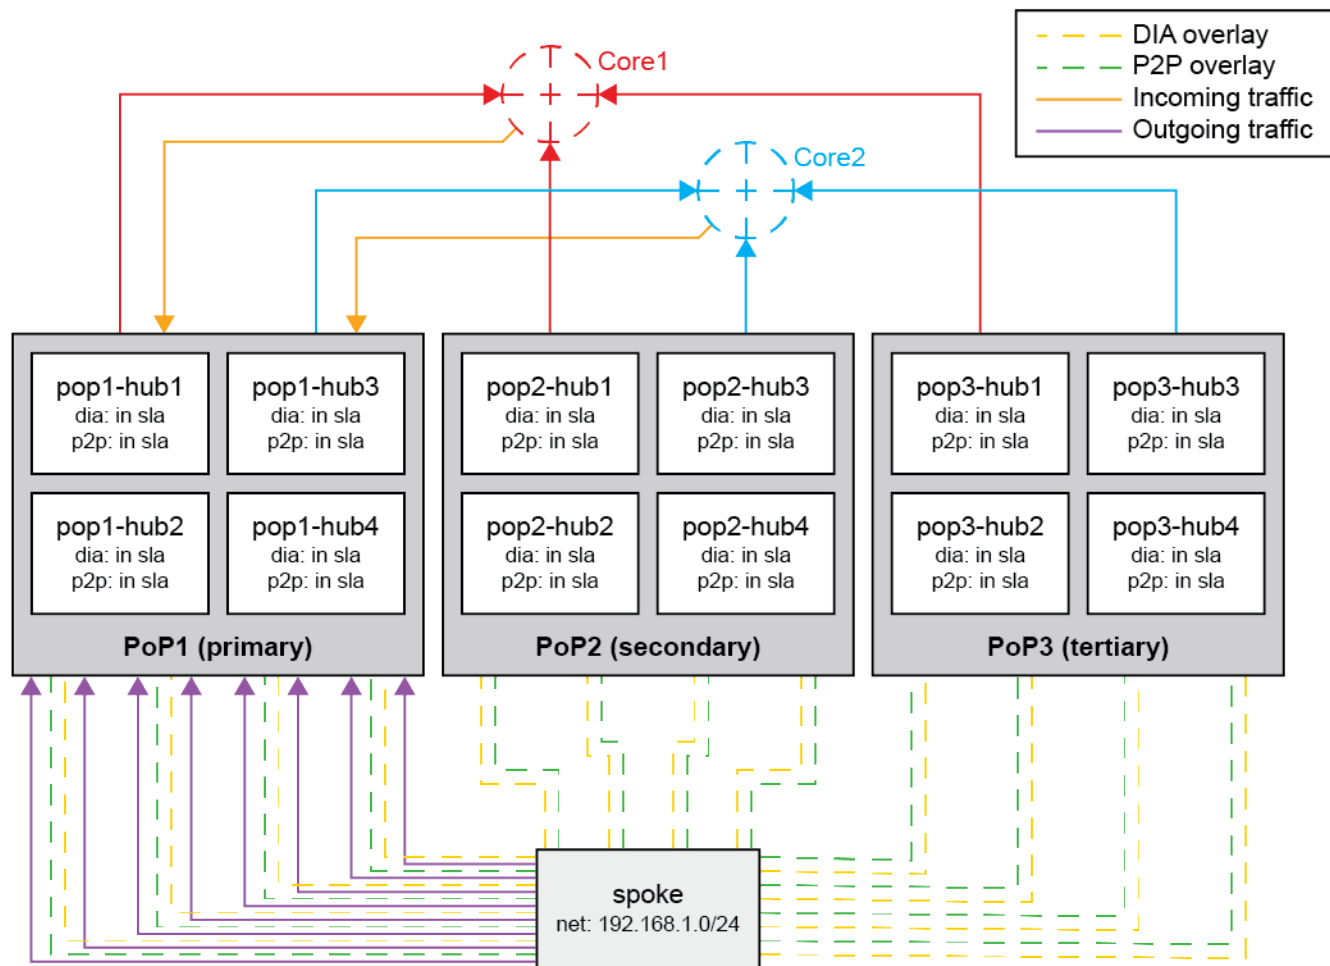

Dst address(1):
  0.0.0.0-255.255.255.255
```

New traffic switches back to the backup shortcut while the primary shortcut is still out of SLA.

SD-WAN multi-PoP multi-hub large scale design and failover - NEW

FortiOS 7.2.0 introduced a feature to define the minimum number of SD-WAN interface members that must meet SLA in order for the spoke to select a hub to process its SD-WAN traffic. This design is suitable for a single-PoP multi-hub architecture in order to achieve hub-to-hub failover. See [Using multiple members per SD-WAN neighbor configuration on page 883](#).

In FortiOS 7.4.1 and later, the design is enhanced to support a multi-PoP multi-hub architecture in which incoming and outgoing traffic failover between PoPs is supported.

Based on the preceding diagram, incoming and outgoing traffic to the spoke is preferred over PoP1. If a single hub within PoP1 goes out of SLA, traffic will continue to flow through the PoP. If the minimum number of members to meet SLA in the PoP cannot be met, then traffic will fail over to PoP2.

The following enhancements have been made to support the multi-PoP failover scenario.

- Add `minimum-sla-meet-members` setting in the SD-WAN zone configurations and `zone-mode` setting in the SD-WAN service configurations:

```
config system sdwan
  config zone
    edit <name>
      set minimum-sla-meet-members <integer>
    next
  end
  config service
    edit <id>
      set mode sla
      set zone-mode {enable | disable}
    next
  end
end
```

When `zone-mode` is enabled on a SD-WAN service rule, the traffic is steered based on the status of the zone.

The state of the health check referenced in the SD-WAN service can be defined as follows:

- If the number of in SLA members in a zone is less than the `minimum-sla-meet-members`, then the zone's state is out of SLA; otherwise, it is in SLA.
- If a zone's state is out of SLA, then all members in the zone are out of SLA.
- If a zone's state is in SLA, then the health check's state of individual members in the zone is determined by its own state.
- Add `service-id` setting in the SD-WAN neighbor configurations:

```
config system sdwan
  config neighbor
    edit <bgp_neighbor_ip>
      set member <member_id>
      set service-id <id>
    next
  end
end
```

The SD-WAN neighbor's behavior can be determined by SD-WAN service and naturally synchronizes with SD-WAN service.

- The SD-WAN service defines priority zones, whose SLA state determines the advertised community preferable string.
- The SD-WAN service defines the `hold-down-time`, which determines how long an advertised community preferable string can be kept when it is expected to be changed.
- Add `sla-stickness` setting in the SD-WAN service configurations:

```
config system sdwan
  config service
    edit <id>
      set mode sla
      set sla-stickness {enable | disable}
    next
  end
end
```

The switch-over of an existing session is determined as follows:

- If the outgoing interface of the session is in SLA, then the session can keep its outgoing interface.
- Otherwise, the session switches to a preferable path if one exists.
- Allow the neighbor group to be configured in the SD-WAN neighbor configurations:

```
config system sdwan
  config neighbor
    edit <bgp_neighbor_group>
      set member <member_id>
      set health-check <name>
      set sla-id <id>
    next
  end
end
```

Outgoing path control

The outgoing path from spoke to hub operates as follows:

1. Overlays to the primary and secondary PoP are assigned separately into an SD-WAN primary and secondary zone on the spoke.
2. One SD-WAN service rule is defined to include these zones as SD-WAN members.
3. When the primary zone is in SLA (`minimum-sla-meet-members` is met), the SD-WAN service rule steers traffic to the in SLA overlay members.
4. When the primary zone is out of SLA (`minimum-sla-meet-members` is not met), the SD-WAN service rule steers traffic to the in SLA overlay members in the secondary zone.
5. When the primary zone SLA is recovered:
 - a. If `sla-stickness` is disabled on the SD-WAN service rule, then traffic will wait the duration of the `hold-down-time` before switching back to in SLA overlays in the primary zone.
 - b. If `sla-stickness` is enabled on the SD-WAN service rule, then existing traffic will be kept on the in SLA overlays on the secondary zone, but new traffic will be steered to in SLA overlays in the primary zone.

Incoming path control

The incoming traffic from the core/external peers, to PoP, to spoke operates as follows:

1. When the primary zone is in SLA, the spoke uses the preferable route map to advertise local routes with the in SLA community to hubs in the primary and secondary PoPs.
 - a. Hubs in the primary PoP translate the in SLA community into a short AS path and advertise it to external peers to attract incoming traffic.
 - b. Hubs in the secondary PoP translate the in SLA community into a longer AS path and advertise it to external peers to deflect incoming traffic.
2. If the number of in SLA overlays in the primary zone is less than the `minimum-sla-meet-members`, then the spoke will use the default route map to advertise routes instead of with an out of SLA community to hubs in the primary PoP.
 - a. Hubs in the primary PoP translate the out of SLA community into a longest AS path, and advertise it to external peers to deflect incoming traffic.
 - b. As a result, inbound traffic is routed to hubs in the secondary PoP.
3. When the primary zone SLA is recovered:
 - a. The spoke will wait the duration of the predefined `hold-down-time` in the SD-WAN service rule to use the preferable route map again to advertise routes with the in SLA community to hubs in the primary PoP.
 - b. As a result, inbound traffic will be routed back to hubs in the primary PoP.

Neighbor group configuration

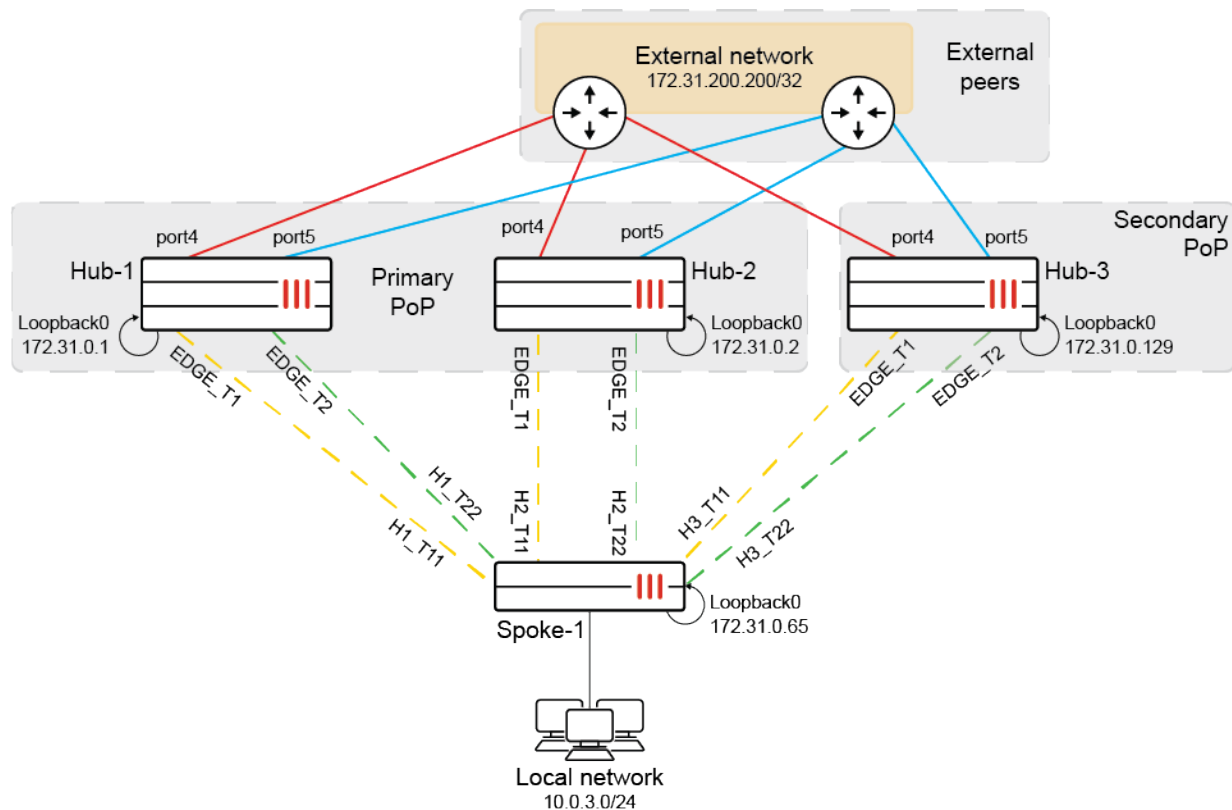

By configuring the neighbor group for spokes under the hub's SD-WAN neighbor configuration, if all paths from the hub to external peers are detected as out of SLA, then the hub will use the default route map to deny external routes to spokes that belong to this neighbor group defined on the hub. As a result, spokes will skip that specific hub and connect to external peers from other hubs.

This allows spokes to only measure overlay quality to each hub, and hubs to manage health checks to services by external peers. This significantly decreases the number of health check probes directly from the spoke to services and decreases the overall complexity. The complexity is further simplified by using multiple VRFs or segmentation where each spoke needs to send health check probes.

Example

This example configuration contains the following components:

- Two PoPs:
 - The primary PoP has two hubs (Hub-1 and Hub-2).
 - The secondary PoP has one hub (Hub-3).
- Spoke-1 has six overlays, with two overlay connections to each hub.
- Spoke-1 has three BGP neighbors, with one BGP neighbor for each hub.
 - All BGP neighbors are established on loopback IPs.
- Each hub has two paths to external peers.

Normally, outbound and inbound traffic go through hubs in the primary PoP. If the number of in SLA overlays to the primary PoP is less than the `minimum-sla-meet-members` (set to 2 in this example), bi-directional traffic needs to be switched to hubs in the secondary PoP. But when the primary PoP recovers and the `minimum-sla-meet-members` is met again, bi-directional traffic is forced back to hubs in the primary PoP after the predefined `hold-down-time` duration.

The hubs do not require SD-WAN configurations to the spokes. However, they use SD-WAN for connections to external peer routers.

Configuring the FortiGates

The following configurations highlight important routing and SD-WAN settings that must be configured on the spoke and the hubs. It is assumed that other configurations such as underlays, IPsec VPN overlays, loopbacks, static routes, and so on are already configured.

To configure Spoke-1:

1. Create the primary (PoP1) and secondary (PoP2) zones, and set the `minimum-sla-meet-members` to 2 on PoP1:

```
config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
    edit "PoP1"
      set minimum-sla-meet-members 2
    next
    edit "PoP2"
    next
  end
end
```

2. Add the overlay members to each zone. Four overlays are defined for PoP1, and two overlays are defined for PoP2:

```
config system sdwan
  config members
    edit 1
      set interface "H1_T11"
      set zone "PoP1"
    next
    edit 2
      set interface "H1_T22"
      set zone "PoP1"
    next
    edit 3
      set interface "H2_T11"
      set zone "PoP1"
    next
    edit 4
      set interface "H2_T22"
      set zone "PoP1"
    next
    edit 5
      set interface "H3_T11"
      set zone "PoP2"
    next
    edit 6
      set interface "H3_T22"
      set zone "PoP2"
    next
  end
end
```

3. Configure a performance SLA health check to a probe server behind the three hubs:

```
config system sdwan
  config health-check
    edit "Hubs"
      set server "172.31.100.100"
      set source 172.31.0.65
      set members 0
      config sla
```

```

        edit 1
            set link-cost-factor latency
            set latency-threshold 200
        next
    end
next
end
end
end

```

4. Configure the service rule with the following settings: use SLA mode, enable zone mode to steer traffic based on the zone statuses, enable `sla-stickiness`, and use a 30-second hold down so that upon a recovery, existing sessions will remain on the secondary PoP while new sessions will switch back to the primary PoP once the 30-second duration ends:

```

config system sdwan
    config service
        edit 1
            set mode sla
            set zone-mode enable
            set dst "all"
            set src "CORP_LAN"
            set hold-down-time 30
            set sla-stickiness enable
            config sla
                edit "Hubs"
                    set id 1
                next
            end
            set priority-zone "PoP1" "PoP2"
        next
    end
end
end

```

Since the PoP1 zone is specified before PoP2, PoP1 is regarded as the primary and preferred over the PoP2 zone.

5. Configure the `in_sla` and `out_sla` route maps that define the communities that are advertised to the hub when the zones are in and out of SLA.

- a. Configure the access list:

```

config router access-list
    edit "net10"
        config rule
            edit 1
                set prefix 10.0.3.0 255.255.255.0
            next
        end
    next
end

```

- b. Configure the route maps:

```

config router route-map
    edit "in_sla"
        config rule
            edit 1
                set match-ip-address "net10"
                set set-community "10:1"
            next
        end
    end
end

```

```

        end
    next
    edit "out_sla"
        config rule
            edit 1
                set match-ip-address "net10"
                set set-community "10:2"
            next
        end
    next
end

```

- 6. Configure the default route map for out of SLA scenarios, preferable route map for in SLA scenarios, and the local network to be advertised:**

```

config router bgp
    config neighbor
        edit "172.31.0.1"
            ...
            set route-map-out "out_sla"
            set route-map-out-preferable "in_sla"
            ...
        next
        edit "172.31.0.2"
            ...
            set route-map-out "out_sla"
            set route-map-out-preferable "in_sla"
            ...
        next
        edit "172.31.0.129"
            ...
            set route-map-out "out_sla"
            set route-map-out-preferable "in_sla"
            ...
        next
    end
    config network
        edit 1
            set prefix 10.0.3.0 255.255.255.0
        next
    end
    ...
end

```

- 7. Define SD-WAN neighbors for each hub. The `minimum-sla-meet-members` is configured for the Hub-1 neighbor so that bi-directional traffic goes through Hub-1 as long as the in SLA overlays to Hub-1 are no less than 1. Associate the previously defined service rule to each SD-WAN neighbor:**

```

config system sdwan
    config neighbor
        edit "172.31.0.1"
            set member 1 2
            set minimum-sla-meet-members 1
            set service-id 1
        next
        edit "172.31.0.2"
            set member 3 4

```

```

        set service-id 1
    next
    edit "172.31.0.129"
        set member 5 6
        set service-id 1
    next
end
end
end

```

To configure the hubs:

1. Configure the SD-WAN zone, members, and health check for the external connections to peer routers. Performance SLA health checks are sent to external servers in order to measure the health of the external connections:

```

config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "port4"
        next
        edit 2
            set interface "port5"
        next
    end
    config health-check
        edit "external_peers"
            set server "10.0.1.2"
            set members 1 2
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 200
                next
            end
        next
    end
end
end
end

```

2. Configure the route maps for in and out of SLA scenarios. When out of SLA (one of the external connections is down), external routes are denied to be advertised to the spokes that are part of the neighbor group.

a. Configure the access list:

```

config router access-list
    edit "net_Lo"
        config rule
            edit 1
                set prefix 172.31.200.200 255.255.255.255
            next
        end
    next
end
end

```

b. Configure the route maps:

```

config router route-map
  edit "in_sla"
    config rule
      edit 1
        set match-ip-address "net_Lo"
      next
    end
  next
  edit "out_sla"
    config rule
      edit 1
        set action deny routes
        set match-ip-address "net_Lo"
      next
    end
  next
end

```

- 3.** In the BGP settings, configure the external network prefix to advertise. Then configure the neighbor group and neighbor range for the spokes. Configure the preferable and default route maps to define the behavior when the external connections are in and out of SLA:

```

config router bgp
  ...
  config network
    edit 1
      set prefix 172.31.200.200 255.255.255.255
    next
  end
  config neighbor-group
    edit "EDGE"
      ...
      set route-map-out "out_sla"
      set route-map-out-preferable "in_sla"
      ...
    next
  end
  config neighbor-range
    edit 1
      set prefix 172.31.0.64 255.255.255.192
      set neighbor-group "EDGE"
    next
  end
  ...
end

```

- 4.** Configure the SD-WAN neighbor to match the neighbor group that includes spokes as members. Specify that at least one of the external peer connections needs to be up to be considered in SLA:

```

config system sdwan
  config neighbor
    edit "EDGE"
      set member 1 2
      set minimum-sla-meet-members 1
      set health-check "external_peers"
    end
  end
end

```

```

        set sla-id 1
    next
end
end

```

Testing and verification

The following tests use diagnostic commands on various FortiGates to verify the connections in the SD-WAN configuration.

Test case 1: the primary PoP and Hub-1 are in SLA

To verify the configuration:

1. Verify the SD-WAN service rules status on Spoke-1. When all six overlays are in SLA on Spoke-1, the primary PoP and primary zone PoP1 are preferred. In particular, the overlay H1_T11 over PoP1 is preferred:

```

Spoke-1 (root) # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x1c200 use-shortcut-sla use-shortcut sla-
stickiness
Tie break: cfg
Gen(1), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(sla), sla-
compare-order
Hold down time(30) seconds, Hold start at 362646 second, now 362646
Service role: standalone
Members(6):
  1: Seq_num(1 H1_T11 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  2: Seq_num(2 H1_T22 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  3: Seq_num(3 H2_T11 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  4: Seq_num(4 H2_T22 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  5: Seq_num(5 H3_T11 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),

Src address(1):
  10.0.0.0-10.255.255.255
Dst address(1):
  0.0.0.0-255.255.255.255

```

2. Verify the BGP learned routes on Hub-1. The local route with in SLA community 10:1 is advertised to all hubs. Though, the AS paths on Hub-1 and Hub-2 are shorter than Hub-3:

```

PoP1-Hub1 (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
Not advertised to any peer
Original VRF 0
Local, (Received from a RR-client)
172.31.0.65 from 172.31.0.65 (172.31.0.65)
Origin IGP metric 0, localpref 100, valid, internal, best
Community: 10:1
Last update: Mon Jul 17 15:16:57 2023

```

3. Send traffic from a host behind Spoke-1 to 172.31.200.200.
4. Run a sniffer trace on Spoke-1. Traffic leaves and returns on the H1_T11 overlay :

```
Spoke-1 (root) # diagnose sniffer packet any 'host 172.31.200.200' 4
interfaces=[any]
filters=[host 172.31.200.200]
5.098248 port4 in 10.0.3.2 -> 172.31.200.200: icmp: echo request
5.098339 H1_T11 out 10.0.3.2 -> 172.31.200.200: icmp: echo request
5.098618 H1_T11 in 172.31.200.200 -> 10.0.3.2: icmp: echo reply
5.098750 port4 out 172.31.200.200 -> 10.0.3.2: icmp: echo reply
```

Test case 2: a single SD-WAN member on Hub-1 is out of SLA

Hub-1 and PoP1 are still preferred in this scenario.

To verify the configuration:

1. Verify the health check status on Spoke-1. The H1_T11 overlay on Hub-1/PoP1 is out of SLA:

```
Spoke-1 (root) # diagnose sys sdwan health-check
Health Check(Hubs):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(220.214), jitter(0.015), mos
(4.104), bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x0
Seq(2 H1_T22): state(alive), packet-loss(0.000%) latency(0.196), jitter(0.014), mos
(4.404), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(3 H2_T11): state(alive), packet-loss(0.000%) latency(0.173), jitter(0.008), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999997), bandwidth-bi(1999995) sla_map=0x1
...
```

2. Verify the SD-WAN neighbor status. The SD-WAN neighbor still displays Hub-1's zone status as pass/alive:

```
Spoke-1 (root) # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
Selected role(standalone) last_secondary_select_time/current_time in seconds
0/436439
Neighbor(172.31.0.1): member(1 2)role(standalone)
Health-check(:0) sla-pass selected alive
Neighbor(172.31.0.2): member(3 4)role(standalone)
Health-check(:0) sla-pass selected alive
Neighbor(172.31.0.129): member(5 6)role(standalone)
Health-check(:0) sla-pass selected alive
```

3. Verify the SD-WAN service rules status. Spoke-1 steers traffic to the H1_T22 overlay through Hub-1:

```
Spoke-1 (root) # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x1c200 use-shortcut-sla use-shortcut sla-
stickiness
Tie break: cfg
Gen(2), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(sla), sla-
compare-order
Hold down time(30) seconds, Hold start at 364162 second, now 364162
Service role: standalone
Members(6):
1: Seq_num(2 H1_T22 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
2: Seq_num(3 H2_T11 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
```

```

3: Seq_num(4 H2_T22 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
4: Seq_num(5 H3_T11 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
5: Seq_num(6 H3_T22 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
6: Seq_num(1 H1_T11 PoP1), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected
Src address(1):
10.0.0.0-10.255.255.255
Dst address(1):
0.0.0.0-255.255.255.255

```

4. Verify the BGP learned routes on Hub-1. The hubs continue to receive community 10:1 from the spoke and continue to route incoming traffic through Hub-1:

```

PoP1-Hub1 (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
Not advertised to any peer
Original VRF 0
Local, (Received from a RR-client)
172.31.0.65 from 172.31.0.65 (172.31.0.65)
Origin IGP metric 0, localpref 100, valid, internal, best
Community: 10:1
Last update: Mon Jul 17 15:16:57 2023

```

5. Send traffic from a host behind Spoke-1 to 172.31.200.200.
6. Run a sniffer trace on Spoke-1. Traffic leaves and returns on the H1_T22 overlay:

```

Spoke-1 (root) # diagnose sniffer packet any 'host 172.31.200.200' 4
interfaces=[any]
filters=[host 172.31.200.200]
25.299006 port4 in 10.0.3.2 -> 172.31.200.200: icmp: echo request
25.299080 H1_T22 out 10.0.3.2 -> 172.31.200.200: icmp: echo request
25.299323 H1_T22 in 172.31.200.200 -> 10.0.3.2: icmp: echo reply
25.299349 port4 out 172.31.200.200 -> 10.0.3.2: icmp: echo reply

```

Test case 3: both SD-WAN members on Hub-1 are out of SLA

Other in SLA overlays in zone PoP1 though Hub-2 are still preferred over PoP2 in this scenario.

To verify the configuration:

1. Verify the health check status on Spoke-1. Both H1_T11 and H1_T22 overlays on Hub-1/PoP1 are out of SLA:

```

Spoke-1 (root) # diagnose sys sdwan health-check
Health Check(Hubs):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(220.220), jitter(0.018), mos
(4.103), bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x0
Seq(2 H1_T22): state(alive), packet-loss(0.000%) latency(220.174), jitter(0.007), mos
(4.104), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x0
Seq(3 H2_T11): state(alive), packet-loss(0.000%) latency(0.184), jitter(0.015), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999997), bandwidth-bi(1999995) sla_map=0x1
Seq(4 H2_T22): state(alive), packet-loss(0.000%) latency(0.171), jitter(0.008), mos
(4.404), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(5 H3_T11): state(alive), packet-loss(0.000%) latency(0.173), jitter(0.011), mos

```

```
(4.404), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(6 H3_T22): state(alive), packet-loss(0.000%) latency(0.179), jitter(0.011), mos
(4.404), bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1
```

2. Verify the SD-WAN neighbor status. The SD-WAN neighbor displays Hub-1's zone status as failed. However, SD-WAN Hub-2 is pass/alive:

```
Spoke-1 (root) # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
    Selected role(standalone) last_secondary_select_time/current_time in seconds
0/436535
Neighbor(172.31.0.1): member(1 2)role(standalone)
    Health-check(:0) sla-fail alive
Neighbor(172.31.0.2): member(3 4)role(standalone)
    Health-check(:0) sla-pass selected alive
Neighbor(172.31.0.129): member(5 6)role(standalone)
    Health-check(:0) sla-pass selected alive
```

3. Verify the SD-WAN service rules status. Spoke-1 steers traffic to the H2_T11 overlay through Hub-2:

```
Spoke-1 (root) # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x1c200 use-shortcut-sla use-shortcut sla-
stickiness
    Tie break: cfg
    Gen(3), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(sla), sla-
compare-order
    Hold down time(30) seconds, Hold start at 364489 second, now 364490
    Service role: standalone
    Members(6):
        1: Seq_num(3 H2_T11 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
        2: Seq_num(4 H2_T22 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
        3: Seq_num(5 H3_T11 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
        4: Seq_num(6 H3_T22 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
        5: Seq_num(1 H1_T11 PoP1), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected
        6: Seq_num(2 H1_T22 PoP1), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected
    Src address(1):
        10.0.0.0-10.255.255.255
    Dst address(1):
        0.0.0.0-255.255.255.255
```

4. Verify the BGP learned routes on Hub-1 and Hub-2. Hub-2 and Hub-3 continue to receive community 10:1 from Spoke-1, but Hub-1 receives the out of SLA community of 10:2.

a. On Hub-1:

```
PoP1-Hub1 (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
    Not advertised to any peer
    Original VRF 0
    Local, (Received from a RR-client)
        172.31.0.65 from 172.31.0.65 (172.31.0.65)
```

```
Origin IGP metric 0, localpref 100, valid, internal, best
Community: 10:2
Last update: Mon Jul 17 18:08:58 2023
```

b. On Hub-2:

```
PoP1-Hub2 (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
Not advertised to any peer
Original VRF 0
Local, (Received from a RR-client)
172.31.0.65 from 172.31.0.65 (172.31.0.65)
Origin IGP metric 0, localpref 100, valid, internal, best
Community: 10:1
Last update: Mon Jul 17 15:31:43 2023
```

5. Send traffic from a host behind Spoke-1 to 172.31.200.200.

6. Run a sniffer trace on Spoke-1. Traffic leaves and returns on the H2_T11 overlay:

```
Spoke-1 (root) # diagnose sniffer packet any 'host 172.31.200.200' 4
interfaces=[any]
filters=[host 172.31.200.200]
13.726009 port4 in 10.0.3.2 -> 172.31.200.200: icmp: echo request
13.726075 H2_T11 out 10.0.3.2 -> 172.31.200.200: icmp: echo request

13.726354 H2_T11 in 172.31.200.200 -> 10.0.3.2: icmp: echo reply
13.726382 port4 out 172.31.200.200 -> 10.0.3.2: icmp: echo reply
```

Test case 4: three SD-WAN members on PoP1 are out of SLA

The number of in SLA overlays in zone PoP1 is less than the `minimum-sla-meet-members` in zone PoP1. The SD-WAN service rule for Hub-2 is forcibly marked as `sla(0x0)` or out of SLA.

To verify the configuration:

1. Verify the health check status on Spoke-1. All three H1_T11, H1_T22, and H2_T11 overlays on PoP1 are out of SLA:

```
Spoke-1 (root) # diagnose sys sdwan health-check
Health Check(Hubs):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(220.219), jitter(0.019), mos
(4.103), bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x0
Seq(2 H1_T22): state(alive), packet-loss(0.000%) latency(220.184), jitter(0.008), mos
(4.104), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x0
Seq(3 H2_T11): state(alive), packet-loss(0.000%) latency(220.171), jitter(0.009), mos
(4.104), bandwidth-up(999998), bandwidth-dw(999997), bandwidth-bi(1999995) sla_map=0x0
Seq(4 H2_T22): state(alive), packet-loss(0.000%) latency(0.180), jitter(0.013), mos
(4.404), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(5 H3_T11): state(alive), packet-loss(0.000%) latency(0.174), jitter(0.014), mos
(4.404), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(6 H3_T22): state(alive), packet-loss(0.000%) latency(0.179), jitter(0.015), mos
(4.404), bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1
```

2. Verify the SD-WAN neighbor status. The SD-WAN neighbor displays Hub-1 and Hub-2's zone status as failed:

```

Spoke-1 (root) # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
    Selected role(standalone) last_secondary_select_time/current_time in seconds
0/436605
Neighbor(172.31.0.1): member(1 2)role(standalone)
    Health-check(:0)    sla-fail alive
Neighbor(172.31.0.2): member(3 4)role(standalone)
    Health-check(:0)    sla-fail alive
Neighbor(172.31.0.129): member(5 6)role(standalone)
    Health-check(:0)    sla-pass selected alive

```

3. Verify the SD-WAN service rules status. Since the minimum SLA members is not met for the primary zone (PoP1), the remaining overlay in PoP1 associated with the SD-WAN service rule is forcibly set to out of SLA. Spoke-1 steers traffic to the H3_T11 overlay through Hub-3:

```

Spoke-1 (root) # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x1c200 use-shortcut-sla use-shortcut sla-
stickiness
    Tie break: cfg
    Gen(6), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(sla), sla-
compare-order
Hold down time(30) seconds, Hold start at 365341 second, now 365341
    Service role: standalone
    Members(6):
        1: Seq_num(5 H3_T11 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
        2: Seq_num(6 H3_T22 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
        3: Seq_num(1 H1_T11 PoP1), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected
        4: Seq_num(2 H1_T22 PoP1), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected
        5: Seq_num(3 H2_T11 PoP1), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected
        6: Seq_num(4 H2_T22 PoP1), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected
    Src address(1):
        10.0.0.0-10.255.255.255
    Dst address(1):
        0.0.0.0-255.255.255.255

```

4. Verify the BGP learned routes on each hub. Hub-3 continues to receive community 10:1 from Spoke-1, but Hub-1 and Hub-2 receive the out of SLA community of 10:2.

a. On Hub-1:

```

PoP1-Hub1 (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
    Not advertised to any peer
    Original VRF 0
    Local, (Received from a RR-client)
        172.31.0.65 from 172.31.0.65 (172.31.0.65)
        Origin IGP metric 0, localpref 100, valid, internal, best
        Community: 10:2
        Last update: Mon Jul 17 18:22:14 2023

```

b. On Hub-2:

```
PoP1-Hub2 (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  Local, (Received from a RR-client)
    172.31.0.65 from 172.31.0.65 (172.31.0.65)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Community: 10:2
      Last update: Mon Jul 17 18:37:53 2023
```

c. On Hub-3:

```
PoP2-Hub3 (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  Local, (Received from a RR-client)
    172.31.0.65 from 172.31.0.65 (172.31.0.65)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Community: 10:1
      Last update: Mon Jul 17 14:39:04 2023
```

5. Send traffic from a host behind Spoke-1 to 172.31.200.200.

6. Run a sniffer trace on Spoke-1. Traffic leaves and returns on the H3_T11 overlay:

```
Spoke-1 (root) # diagnose sniffer packet any 'host 172.31.200.200' 4
interfaces=[any]
filters=[host 172.31.200.200]
38.501449 port4 in 10.0.3.2 -> 172.31.200.200: icmp: echo request
38.501519 H3_T11 out 10.0.3.2 -> 172.31.200.200: icmp: echo request
38.501818 H3_T11 in 172.31.200.200 -> 10.0.3.2: icmp: echo reply
38.501845 port4 out 172.31.200.200 -> 10.0.3.2: icmp: echo reply
```

Test case 5: an SD-WAN member on PoP1 recovers

SD-WAN member H2_T11 recovers and brings the number of overlays in SLA back to being above the `minimum-sla-meet-members` threshold in PoP1. After the hold down time duration (30 seconds), in SLA overlays in zone PoP1 are preferred over PoP2 again. With `sla-stickiness` enabled, existing traffic is kept on H3_T11, but new traffic is steered to H2_T11.

To verify the configuration:

1. Verify the SD-WAN service rules status on Spoke-1. The hold down timer has not yet passed, so H2_T11 is not yet preferred—even though the SLA status is pass/alive:

```
Spoke-1 (root) # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x1c200 use-shortcut-sla use-shortcut sla-
stickiness
  Tie break: cfg
    Gen(16), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(sla), sla-
compare-order
  Hold down time(30) seconds, Hold start at 431972 second, now 432000
  Service role: standalone
```

```

Members(6):
  1: Seq_num(5 H3_T11 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
  2: Seq_num(6 H3_T22 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),

  5: Seq_num(3 H2_T11 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  6: Seq_num(4 H2_T22 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected

```

2. Verify the SD-WAN service rules status again after the hold down timer passes. H2_T11 and H2_T22 from PoP1 are now preferred:

```

Spoke-1 (root) # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x1c200 use-shortcut-sla use-shortcut sla-
stickiness
Tie break: cfg
  Gen(17), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(sla), sla-
compare-order
Hold down time(30) seconds, Hold start at 432003 second, now 432003
Service role: standalone
Members(6):
  1: Seq_num(3 H2_T11 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  2: Seq_num(4 H2_T22 PoP1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
  3: Seq_num(5 H3_T11 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
  4: Seq_num(6 H3_T22 PoP2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected
  5: Seq_num(1 H1_T11 PoP1), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected
  6: Seq_num(2 H1_T22 PoP1), alive, sla(0x0), gid(0), cfg_order(0), local cost(0),
selected

```

3. Verify the BGP learned routes on Hub-2, which now receives community 10:1 from Spoke-1:

```

PoP1-Hub2 (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
Not advertised to any peer
Original VRF 0
Local, (Received from a RR-client)
  172.31.0.65 from 172.31.0.65 (172.31.0.65)
    Origin IGP metric 0, localpref 100, valid, internal, best
Community: 10:1
Last update: Tue Jul 18 14:41:32 2023

```

4. Send traffic from a host behind Spoke-1 to 172.31.200.200.
5. Run a sniffer trace on Spoke-1. Because of sla-stickiness, the existing traffic is kept on H3_T11:

```

Spoke-1 (root) # diagnose sniffer packet any 'host 172.31.200.200' 4
interfaces=[any]

```

```
filters=[host 172.31.200.200]

0.202708 port4 in 10.0.3.2 -> 172.31.200.200: icmp: echo request
0.202724 H3_T11 out 10.0.3.2 -> 172.31.200.200: icmp: echo request
0.202911 H3_T11 in 172.31.200.200 -> 10.0.3.2: icmp: echo reply
0.202934 port4 out 172.31.200.200 -> 10.0.3.2: icmp: echo reply
```

Test case 6: Hub-1 has an in SLA path to external peers

Since Hub-1 has an in SLA path to external peers, it will advertise the external route with destination 172.31.200.200/32 to Spoke-1.

To verify the configuration:

1. Verify the health check status on Hub-1. Note that port4 meets SLA, but port5 does not:

```
PoP1-Hub1 (root) # diagnose sys sdwan health-check
Health Check(external_peers):
Seq(1 port4): state(alive), packet-loss(0.000%) latency(0.161), jitter(0.009), mos
(4.404), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(2 port5): state(dead), packet-loss(100.000%) sla_map=0x0
```

2. Verify the SD-WAN neighbor status. The minimum-sla-meet-members threshold of 1 is still met:

```
PoP1-Hub1 (root) # diagnose sys sdwan neighbor
Neighbor(EDGE): member(1 2)role(standalone)
Health-check(external_peers:1) sla-pass selected alive
```

3. Verify the BGP learned routes. Hub-1 still advertises the external route to the Spoke-1 BGP neighbor:

```
PoP1-Hub1 (root) # get router info bgp neighbors 172.31.0.65 advertised-routes
VRF 0 BGP table version is 13, local router ID is 172.31.0.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network                Next Hop        Metric      LocPrf  Weight  RouteTag Path
*>i172.31.200.200/32      172.31.0.1      100         32768      0          i <-/->
Total number of prefixes 1
```

Test case 7: all external peers on Hub-1 are out of SLA

In this case, Hub-1 will now advertise the default route map, which denies the advertisement of the external route. Spoke-1 will now route traffic to the next hub.

To verify the configuration:

1. Verify the health check status on Hub-1. Note that port4 and port5 do not meet SLA:

```
PoP1-Hub1 (root) # diagnose sys sdwan health-check
Health Check(external_peers):
Seq(1 port4): state(dead), packet-loss(100.000%) sla_map=0x0
Seq(2 port5): state(dead), packet-loss(100.000%) sla_map=0x0
```

2. Verify the SD-WAN neighbor status. The minimum-sla-meet-members threshold of 1 is not met:

```
PoP1-Hub1 (root) # diagnose sys sdwan neighbor
Neighbor(EDGE): member(1 2)role(standalone)
Health-check(external_peers:1) sla-fail dead
```

3. Verify the BGP learned routes. Hub-1 does not advertise any external routes to the Spoke-1 BGP neighbor:

```
PoP1-Hub1 (root) # get router info bgp neighbors 172.31.0.65 advertised-routes
% No prefix for neighbor 172.31.0.65
```

Using a single IKE elector in ADVPN to match all SD-WAN control plane traffic

In the SD-WAN with ADVPN use case, two spokes can communicate with each other on the control plane by an ADVPN shortcut. In order to separate the control traffic from data traffic, the IKE creates a dynamic selector for health check packets sent between the spokes. BGP traffic is also matched by this dynamic IKE selector. Therefore, when spokes establish BGP peering with other spokes, the BGP traffic does not count towards the data traffic and will not impact IPsec idle timeout and shortcut tunnel tear down.

Example

In this example, SD-WAN with ADVPN is configured. The IPsec ADVPN shortcut tunnel is required to tear down when it is idle. SD-WAN health checks are configured, and BGP neighbors established between the spokes is required.

To configure the Hub FortiGate:

1. Configure the phase 1 interface:

```
config vpn ipsec phase1-interface
  edit "Hub"
    set type dynamic
    set interface "port2"
    set ike-version 2
    set peertype any
    set net-device disable
    set proposal aes128-sha256 aes256-sha256 aes128gcm-prfsha256 aes256gcm-prfsha384
    chacha20poly1305-prfsha256
    set add-route disable
    set dpd on-idle
    set auto-discovery-sender enable
    set psksecret *****
    set dpd-retryinterval 60
  end
```

```
    next
end
```

2. Configure the phase 2 interface:

```
config vpn ipsec phase2-interface
    edit "Hub"
        set phase1name "Hub"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
        aes256gcm chacha20poly1305
    next
end
```

3. Configure the VPN interface:

```
config system interface
    edit "Hub"
        set vdom "root"
        set ip 10.10.1.250 255.255.255.255
        set allowaccess ping
        set type tunnel
        set remote-ip 10.10.1.254 255.255.255.0
        set snmp-index 50
        set interface "port2"
    next
end
```

4. Configure the BGP settings:

```
config router bgp
    set as 65412
    config neighbor
        edit "10.10.1.1"
            set advertisement-interval 0
            set remote-as 65412
            set route-reflector-client enable
        next
        edit "10.10.1.2"
            set advertisement-interval 0
            set remote-as 65412
            set route-reflector-client enable
        next
    end
    config network
        edit 1
            set prefix 174.16.101.0 255.255.255.0
        next
    end
end
```

To configure the Spoke1 FortiGate:**1. Configure the phase 1 interface:**

```
config vpn ipsec phase1-interface
    edit "Spoke1"
        set interface "port1"
        set ike-version 2
```

```

        set peertype any
        set net-device enable
        set proposal aes128-sha256 aes256-sha256 aes128gcm-prfsha256 aes256gcm-prfsha384
chacha20poly1305-prfsha256
        set add-route disable
        set npu-offload disable
set idle-timeout enable
set idle-timeoutinterval 5
        set auto-discovery-receiver enable
        set remote-gw 172.16.200.4
        set psksecret *****
    next
end

```

2. Configure the phase 2 interface:

```

config vpn ipsec phase2-interface
    edit "Spoke1"
        set phaselname "Spoke1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
    next
end

```

3. Configure the VPN interface:

```

config system interface
    edit "Spoke1"
        set vdom "root"
        set ip 10.10.1.1 255.255.255.255
        set allowaccess ping
        set type tunnel
        set remote-ip 10.10.1.254 255.255.255.0
        set snmp-index 28
        set interface "port1"
    next
end

```

4. Configure the BGP settings:

```

config router bgp
    set as 65412
    config neighbor
        edit "10.10.1.250"
            set advertisement-interval 0
            set remote-as 65412
        next
edit "10.10.1.2"
set remote-as 65412
    next
end
config network
    edit 1
        set prefix 10.1.100.0 255.255.255.0
    next
end
end

```

5. Configure the SD-WAN settings:

```

config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "Spoke1"
        next
    end
    config health-check
        edit "1"
            set server "174.16.101.44"
            set members 0
        next
    end
end

```

To configure the Spoke2 FortiGate:

1. Configure the phase 1 interface:

```

config vpn ipsec phase1-interface
    edit "Spoke2"
        set interface "wan1"
        set ike-version 2
        set peertype any
        set net-device enable
        set proposal aes128-sha256 aes256-sha256 aes128gcm-prfsha256 aes256gcm-prfsha384
chacha20poly1305-prfsha256
        set add-route disable
        set npu-offload disable
        set idle-timeout enable
        set idle-timeoutinterval 5
        set auto-discovery-receiver enable
        set remote-gw 172.16.200.4
        set psksecret *****
    next
end

```

2. Configure the phase 2 interface:

```

config vpn ipsec phase2-interface
    edit "Spoke2"
        set phaselname "Spoke2"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
    next
end

```

3. Configure the VPN interface:

```

config system interface
    edit "Spoke2"
        set vdom "root"
        set ip 10.10.1.2 255.255.255.255
        set allowaccess ping
    end

```

```

        set type tunnel
        set remote-ip 10.10.1.254 255.255.255.0
        set snmp-index 15
        set interface "wan1"
    next
end

```

4. Configure the BGP settings:

```

config router bgp
    set as 65412
    config neighbor
        edit "10.10.1.250"
            set advertisement-interval 0
            set remote-as 65412
        next
        edit "10.10.1.1"
            set remote-as 65412
        next
    end
    config network
        edit 1
            set prefix 192.168.4.0 255.255.255.0
        next
    end
end

```

5. Configure the SD-WAN settings:

```

config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "Spoke2"
        next
    end
    config health-check
        edit "1"
            set server "174.16.101.44"
            set members 0
        next
    end
end

```

To verify the configuration:

1. Send traffic between the spokes to establish the ADVPN shortcut.
2. Verify the IPsec tunnel state on the Spoke1 FortiGate:

```

Spoke1 # diagnose vpn tunnel list
list all ipsec tunnel in vd 0
-----
name=Spoke1_0 ver=2 serial=7 172.16.200.1:0->172.16.200.3:0 tun_id=10.10.1.2 tun_

```

```

npuid=0

```

The dynamic selector is created (highlighted) for SD-WAN control traffic, SD-WAN health checks, and BGP between spokes traffic.

3. Verify the BGP neighbors and check the routing table:

```
Spoke1 # get router info bgp summary
```

```

VRF 0 BGP router identifier 172.16.200.1, local AS number 65412
BGP table version is 8
1 BGP AS-PATH entries
0 BGP community entries

```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
10.10.1.2	4	65412	52	76	7	0	0	00:06:27	1
10.10.1.250	4	65412	70	69	1	0	0	00:58:44	2

```
Total number of neighbors 2
```

4. Stop sending traffic between the spokes, and wait for a few minutes (idle timeout).

5. Verify the IPsec tunnel state on the Spoke1 FortiGate:

```

Spoke1 # diagnose vpn tunnel list
list all ipsec tunnel in vd 0
-----
name=Spoke1 ver=2 serial=1 172.16.200.1:0->172.16.200.4:0 tun_id=172.16.200.4 tun_
id6=:172.16.200.4 dst_mtu=1500 dpd-link=on weight=1
bound_if=19 lgwy=static/1 tun=intf mode=auto/1 encap=none/560 options[0230]=create_dev
frag-rfc role=primary accept_traffic=1 overlay_id=0

proxyid_num=1 child_num=0 refcnt=4 ilast=0 olast=0 ad=r/2
stat: rxp=1467 txp=1469 rxb=60190 txb=60214
dpd: mode=on-demand on=1 idle=20000ms retry=3 count=0 seqno=0
natt: mode=none draft=0 interval=0 remote_port=0
fec: egress=0 ingress=0
proxyid=Spoke1 proto=0 sa=1 ref=3 serial=1 adr
  src: 0:0.0.0.0-255.255.255.255:0

```

The shortcut tunnel between the spokes has been torn down. When data traffic is idle, the BGP traffic does not get sent on the data traffic selector, so the tunnel is not kept alive. This behavior is the expected, which consequently allows the shortcut tunnel to be torn down when idle.

6. Verify the IKE debugs messages to confirm the ADVPN shortcut was torn down:

```

Spoke1 # diagnose debug enable
Spoke1 # diagnose debug application ike -1
...

SD-WAN Overlay-as-a-Service - NEW

SD-WAN Overlay-as-a-Service (OaaS) is supported through a license displayed as *SD-WAN Overlay as a Service* on the *System > FortiGuard* page. Each FortiGate used by the FortiCloud Overlay-as-a-Service portal must have this license applied to it.

To view the status of the OaaS license in the GUI:

1. Go to *System > FortiGuard*.
2. Expand *License Information*. The *SD-WAN Overlay as a Service* license status is listed as:

- **Licensed:** OaaS is currently licensed and will expire on the provided date.

FortiGuard Distribution Network

License Information

Entitlement	Status

To view the status of the OaaS license in the CLI:

1. Verify that the entitlement can be updated:

The SD-WAN Overlay-as-a-Service license is listed as `SWOS` in the CLI.

```
# diagnose test update info
```

```
System contracts:
  FMWR,Wed Dec 20 16:00:00 2023
  SPAM,Wed Dec 20 16:00:00 2023
  SBCL,Wed Dec 20 16:00:00 2023
  SWNO,Wed Dec 20 16:00:00 2023
  SWNM,Wed Sep 27 17:00:00 2023

logid="0100020138" type="event" subtype="system" level="warning" vd="root"
logdesc="FortiGuard SD-WAN Overlay as a Service license expiring" msg="FortiGuard SD-WAN
Overlay Service license will expire in 4 day(s)"
```

Advanced configuration

The following topics provide instructions on SD-WAN advanced configuration:

- [SD-WAN with FGCP HA on page 981](#)
- [Configuring SD-WAN in an HA cluster using internal hardware switches on page 987](#)
- [SD-WAN configuration portability on page 991](#)
- [SD-WAN segmentation over a single overlay on page 997](#)
- [Matching BGP extended community route targets in route maps on page 1012](#)
- [Copying the DSCP value from the session original direction to its reply direction on page 1017](#)

See also [Packet distribution for aggregate static IPsec tunnels in SD-WAN on page 1922](#).

SD-WAN with FGCP HA

This example shows how to convert a standalone FortiGate SD-WAN solution to a FGCP HA cluster with full-mesh WAN set up. This configuration allows you to load balance your internet traffic between multiple ISP links. It also provides redundancy for your internet connection if your primary ISP is unavailable, or if one of the FortiGates in the HA cluster fails.

This example assumes that a standalone FortiGate has already been configured for SD-WAN by following the [SD-WAN quick start on page 704](#).

Standalone FortiGate:

FGCP HA cluster:

The following devices are required to convert the topology to HA:

- A second FortiGate that is the same model running the same firmware version.
- Two switches for connecting each FortiGate's WAN interface to the corresponding ISP modem.

Before you begin:

- Ensure that the licenses and subscriptions on both HA members match.
- Ensure that there are one or more ports reserved for HA heartbeat.
- Ensure you have physical access to both HA members.

Enabling HA and re-cabling the WAN interfaces will cause network interruptions. This procedure should be performed during a maintenance window.

Configuring the standalone FortiGate for HA

After running the following commands, the FortiGate negotiates to establish an HA cluster. You might temporarily lose connectivity with the FortiGate as FGCP negotiations take place and the MAC addresses of the FortiGate interfaces are changed to HA virtual MAC addresses.

This configurations sets the HA mode to active-passive.

The ha1 and ha2 interfaces are configured as the heartbeat interfaces, with priorities set to 200 and 100 respectively. Setting different priorities for the heartbeat interfaces is a best practice, but is not required.

If you have more than one cluster on the same network, each cluster should have a different group ID. Changing the group ID changes the cluster interface's virtual MAC addresses. If the group IP causes a MAC address conflict on your network, select a different group ID.

Enabling override and increasing the device priority means that this FortiGate always becomes the primary unit.

To configure the standalone FortiGate for HA in the GUI:

1. Go to *System > Settings* and change the *Host name* so that the FortiGate can be easily identified as the primary unit.
2. Go to *System > HA* and configure the following options:

Mode	Active-Passive
Device priority	250
Group name	My-cluster
Password	<password>
Heartbeat interfaces	ha1 and ha2
Heartbeat Interface Priority	port2 (ha1): 200 port3 (ha2): 100

Override and the group ID can only be configured from the CLI.

3. Click **OK**.
Connectivity with the FortiGate will temporarily be lost.

To configure the standalone FortiGate for HA in the CLI:

1. Change the host name so that the FortiGate can be easily identified:

```
config system global
    set hostname primary_FG
end
```

2. Configure HA:

```
config system ha
    set mode a-p
    set group-id 100
    set group-name My-cluster
    set password <password>
    set priority 250
    set override enable
    set hbdev ha1 200 ha2 100
end
```

If HA mode does not start after running the above steps, ensure that none of the FortiGate's interfaces use DHCP or PPPoE addressing.

Configuring the secondary FortiGate for HA

The secondary FortiGate must be the same model and running the same firmware version as the primary FortiGate. The HA settings are the same as the for the primary unit, except the secondary device has a lower priority and override is not enabled.

It is best practice to reset the FortiGate to factory default settings prior to configuring HA. This reduces the chance of synchronization problems.

```
# execute factoryreset
This operation will reset the system to factory default!
Do you want to continue? (y/n) y
```

This is unnecessary if the device is new from the factory.

To configure the secondary FortiGate for HA in the GUI:

1. Go to *System > Settings* and change the *Host name* so that the FortiGate can be easily identified as the backup unit.
2. Go to *System > HA* and configure the options the same as for the primary FortiGate, except with a lower priority:

Mode	Active-Passive
Device priority	128
Group name	My-cluster
Password	<password>
Heartbeat interfaces	ha1 and ha2
Heartbeat Interface Priority	port2 (ha1): 200 port3 (ha2): 100

3. Click *OK*.

To configure the secondary FortiGate for HA in the CLI:

1. Change the host name so that the secondary FortiGate can be easily identified:

```
config system global
    set hostname secondary_FG
end
```

2. Configure HA:

```
config system ha
    set mode a-p
    set group-id 100
    set group-name My-cluster
    set password <password>
    set priority 128
    set hbdev ha1 200 ha2 100
end
```

Connecting the heartbeat interfaces between the FortiGates

To connect and check the heartbeat interfaces:

1. Connect the heartbeat interfaces ha1 and ha2 between the primary and secondary FortiGate.
 - a. An HA primary device is selected. Because the primary FortiGate has a higher priority and override enabled, it assumes the role of HA primary.

b. The secondary FortiGate synchronizes its configuration from the primary device.

2. Verify that the checksums match between the primary and secondary FortiGates:

```
# diagnose sys ha checksum cluster

===== FG5H0XXXXXXXXXX0 =====

is_manage_primary()=1, is_root_primary()=1
debugzone
global: 2b e9 81 38 c2 9d 4f db b7 0e 1f 49 42 c6 1e fb

all: 89 1f 63 77 48 8a 30 ee 57 06 ca eb 71 e6 8e ad
```

If all of the cluster members have identical checksums, then their configurations are synchronized. If the checksums are not the same, wait for a few minutes, then repeat the command. Some parts of the configuration might take a significant amount of time to synchronize (tens of minutes).

Connecting other traffic interfaces

After the device configurations are synchronized, you can connect the rest of the traffic interfaces. Making these connections will disrupt traffic as cables are disconnected and reconnected.

Switches must be used between the cluster and the ISPs, and between the cluster and the internal network, as shown in the topology diagram.

Checking cluster operations

The *HA Status* dashboard widget shows the synchronization status. Hover over the host names of each FortiGate in the widget to verify that they are synchronized and have the same checksum.

To view more information about the cluster status, including the number of sessions passing through the cluster members, go to *System > HA*.

See [Check HA synchronization status on page 2540](#) for more information.

Results

1. Browse the internet on a computer in the internal network.
2. Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab to see the bandwidth, volume, and sessions for traffic on the SD-WAN interfaces. See [Results on page 708](#) for details.
3. Go to *Dashboard > Network*, and expand the *SD-WAN* widget to see information about each interface, such as the number of sessions and the bit rate.

Interface	Status	Sessions	Upload	Download
sd-wan				
wan1		49	190 bps	51 bps
wan2		33	2.97 kbps	6.75 kbps

Updated: 14:30:42

Testing HA failover

All traffic should currently be flowing through the primary FortiGate. If it becomes unavailable, traffic fails over to the secondary FortiGate. When the primary FortiGate rejoins the cluster, the secondary FortiGate continues to operate as the primary FortiGate.

To test this, ping a reliable IP address from a computer in the internal network, and then power off the primary FortiGate.

There will be a momentary pause in the ping results until traffic diverts to the backup FortiGate, allowing the ping traffic to continue:

```
64 bytes from 184.25.76.114: icmp_seq=69 ttl=52 time=8.719 ms\
64 bytes from 184.25.76.114: icmp_seq=70 ttl=52 time=8.822 ms\
64 bytes from 184.25.76.114: icmp_seq=74 ttl=52 time=8.901 ms\
Request timeout for icmp_seq 75\
64 bytes from 184.25.76.114: icmp_seq=76 ttl=52 time=8.860 ms\
64 bytes from 184.25.76.114: icmp_seq=77 ttl=52 time=9.174 ms\
64 bytes from 184.25.76.114: icmp_seq=83 ttl=52 time=8.639 ms}
```

If you are using port monitoring, you can also unplug the primary FortiGate's internet facing interface to test failover.

After the secondary FortiGate becomes the primary, you can log into the cluster using the same IP address as before the fail over. If the primary FortiGate is powered off, you will be logged into the backup FortiGate. Check the host name to verify what device you have logged into. The FortiGate continues to operate in HA mode, and if you restart the primary FortiGate, it will rejoin the cluster and act as the backup FortiGate. Traffic is not disrupted when the restarted FortiGate rejoins the cluster.

You can also use the CLI to force an HA failover. See [Force HA failover for testing and demonstrations on page 2569](#) for information.

Testing ISP failover

To test a failover of the redundant internet configuration, you need to simulate a failed internet connection to one of the ports. You can do this by disconnecting power from the wan1 switch, or by disconnecting the wan1 interfaces of both FortiGates from ISP1.

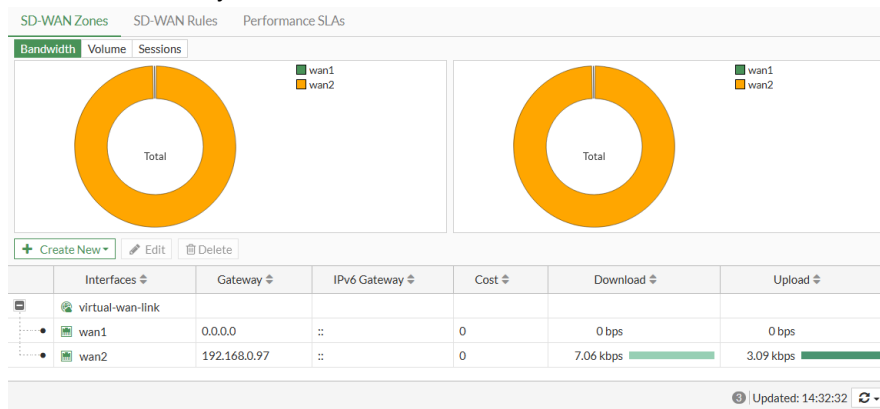

After disconnecting, verify that users still have internet access

- Go to *Dashboard > Network*, and expand the *SD-WAN* widget. The *Upload* and *Download* columns for wan1 show that traffic is not going through that interface.

Interface	Status	Sessions	Upload	Download
sd-wan ⓘ				
wan1	🟢	12	0 bps	0 bps
wan2	🟢	33	2.97 kbps	6.75 kbps

Updated: 14:30:42

- Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab. The *Bandwidth*, *Volume*, and *Sessions* tabs show that traffic is entirely diverted to wan2.

Users on the network should not notice the wan1 failure. If you are using the wan1 gateway IP address to connect to the administrator dashboard, it will appear as though you are still connecting through wan1.

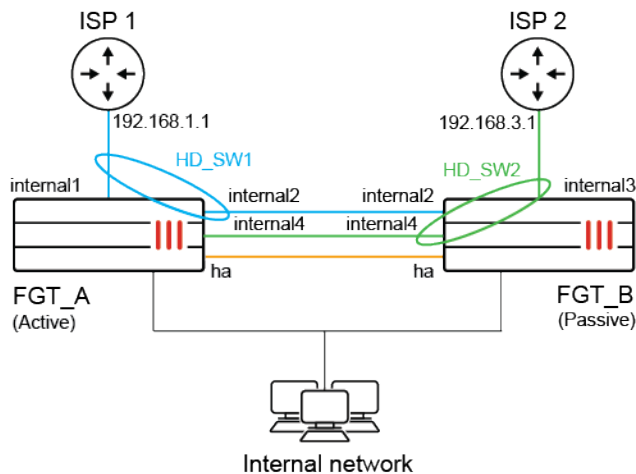

After verifying a successful failover, reestablish the connection to ISP1.

Configuring SD-WAN in an HA cluster using internal hardware switches

In this SD-WAN configuration, two FortiGates in an active-passive (A-P) HA pair are used to provide hardware redundancy. Instead of using external switches to provide a mesh network connection to the ISP routers, the FortiGates use their built-in hardware switches to connect to the ISP routers.

Only FortiGate models that have hardware switches can be used for this solution. Ports in a software switch are not in a forwarding state when a FortiGate is acting as a secondary device in a A-P cluster.

In this topology:

- Two hardware switches are created, HD_SW1 and HD_SW2.
- HD_SW1 is used to connect to ISP 1 Router and includes the internal1 and internal2 ports.
- HD_SW2 is used to connect to ISP 2 Router and includes the internal3 and internal4 ports.
- Another interface on each device is used as the HA heartbeat interface, connecting the two FortiGates in HA.

The FortiGates create two hardware switches to connect to ISP 1 and ISP2. When FGT_A is the primary device, it reaches ISP 1 on internal1 in HD_SW1 and ISP 2 on internal4 in HD_SW2. When FGT_B is the primary device, it reaches ISP 1 on internal2 in HD_SW1 and ISP 2 on internal3 on HD_SW2.

HA failover

This is not a standard HA configuration with external switches. In the case of a device failure, one of the ISPs will no longer be available because the switch that is connected to it will be down.

For example, If FGT_A loses power, HA failover will occur and FGT_B will become the primary unit. Its connection to internal2 on HD_SW1 will also be down, so it will be unable to connect to ISP 1. Its SD-WAN SLAs will be broken, and traffic will only be routed through ISP 2.

A link on a hardware switch cannot be monitored in HA monitor, so it is impossible to perform link failure when a port in either of the hardware switches fails. Performing a link failure is unnecessary in this configuration though, because any link failure on the hardware switch will be experienced by both cluster members. SD-WAN SLA health checks should be used to monitor the health of each ISP.

Failure on a hardware switch or ISP router

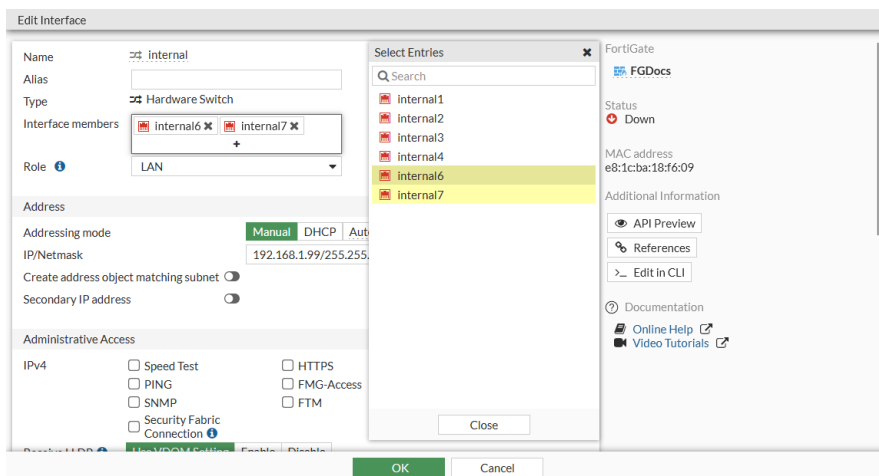

If a hardware switch or switch interface is down, or the ISP router is down, the SD-WAN can detect the broken SLA and continue routing to the other ISP.

For example, if FGT_A is the primary unit, and ISP 2 Router becomes unreachable, the SLA health checks on SD-WAN will detect the broken SLA and cause traffic to stop routing to ISP 2.

Configuration

To configure the HA A-P cluster with internal hardware switches:

1. Configure two FortiGates with internal switches in an A-P HA cluster (follow the steps in [HA active-passive cluster setup on page 2528](#)), starting by connecting the heartbeat interface.
2. When the HA cluster is up, connect to the primary FortiGate's GUI.
3. Remove the existing interface members from the default hardware switch:
 - a. Go to *Network > Interfaces*.
 - b. In the *LAN* section, double-click the *internal* interface to edit it.
 - c. In *Interface Members*, remove all of the interfaces

- d. Click **OK**.
4. Configure the hardware switch interfaces for the two ISPs:
 - a. Go to *Network > Interfaces* and click *Create New > Interface*.
 - b. Enter a name (*HD_SW1*).
 - c. Set *Type* to *Hardware Switch*.
 - d. In *Interface Members*, add two interfaces (*internal1* and *internal2*).
 - e. Set *IP/Netmask* to *192.168.1.2/24*.
 - f. Configure the remaining settings as needed.

The screenshot shows the 'New Interface' configuration window for a FortiGate device. The interface is named 'HD_SW1' and is configured as a 'Hardware Switch'. The VRF ID is set to '0'. Under 'Interface members', 'Internal1' and 'Internal2' are selected. The 'Role' is set to 'LAN'. In the 'Address' section, the 'Addressing mode' is 'Manual', 'DHCP' is selected, and 'Auto-managed by FortiIPAM' and 'PPPoE' are also visible. The 'IP/Netmask' is '192.168.1.2/255.255.255.0'. The 'IPv6 addressing mode' is 'Manual', 'DHCP' is selected, and 'Delegated' is also visible. The 'IPv6 Address/Prefix' is ':::0'. The 'Auto configure IPv6 address' and 'DHCPv6 prefix delegation' options are disabled. The 'Create address object matching subnet' option is enabled. The 'Name' of the address object is 'HD_SW1 address', the 'Destination' is '192.168.1.2/255.255.255.255', and the 'Secondary IP address' is disabled. On the right side, there are links for 'FortiGate', 'FGDocs', 'Additional Information', 'API Preview', 'Documentation', 'Online Help', and 'Video Tutorials'. At the bottom, there are 'OK' and 'Cancel' buttons.

- g. Click **OK**.
- h. Repeat these steps to create a second hardware switch interface (*HD_SW2*) with two interface members (*internal3* and *internal4*) and *IP/Netmask* set to *192.168.3.2/24*.

The screenshot shows the 'New Interface' configuration window for a FortiGate device. The interface is named 'HD_SW2' and is configured as a 'Hardware Switch'. The VRF ID is set to '0'. Under 'Interface members', 'Internal3' and 'Internal4' are selected. The 'Role' is set to 'LAN'. In the 'Address' section, the 'Addressing mode' is 'Manual', 'DHCP' is selected, and 'Auto-managed by FortiIPAM' and 'PPPoE' are also visible. The 'IP/Netmask' is '192.168.3.2/255.255.255.0'. The 'IPv6 addressing mode' is 'Manual', 'DHCP' is selected, and 'Delegated' is also visible. The 'IPv6 Address/Prefix' is ':::0'. The 'Auto configure IPv6 address' and 'DHCPv6 prefix delegation' options are disabled. The 'Create address object matching subnet' option is enabled. The 'Name' of the address object is 'HD_SW2 address', the 'Destination' is '192.168.3.2/255.255.255.0', and the 'Secondary IP address' is disabled. On the right side, there are links for 'FortiGate', 'FGDocs', 'Additional Information', 'API Preview', 'Documentation', 'Online Help', and 'Video Tutorials'. At the bottom, there are 'OK' and 'Cancel' buttons.

To connect the devices as shown in the topology:

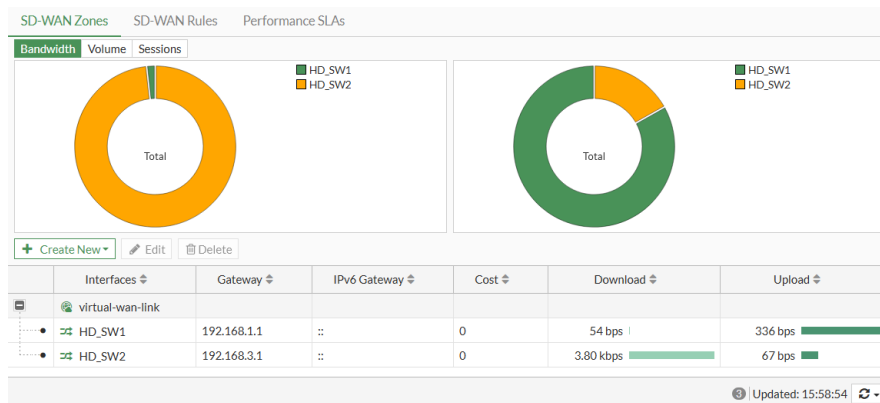

1. Connect the incoming interface to the internal switch on both FortiGates.
2. On FGT_A, connect internal1 of HD_SW1 to ISP 1 Router.
3. On FGT_B, connect internal3 of HD_SW2 to ISP 2 Router.
4. For HD_SW1, connect FGT_A internal2 directly to FGT_B internal2.
5. For HD_SW2, connect FGT_A internal4 directly to FGT_B internal4.

To configure SD-WAN:

The primary FortiGate makes all the SD-WAN decisions.

1. On the primary FortiGate, go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
2. In the *Interface* dropdown, select *HD_SW1*.
3. Leave *SD-WAN Zone* set to *virtual-wan-link*.
4. Enter the *Gateway* address *192.168.1.1*.
5. Click *OK*.
6. Repeat these steps to add the second interface (*HD_SW2*) with the gateway *192.168.3.1*.
7. Click *Apply*.

8. Create a health check:
 - a. Go to *Network > SD-WAN*, select the *Performance SLA* tab, and click *Create New*.
 - b. Set *Name* to *GW_HC*.
 - c. Set *Protocol* to *Ping* and *Servers* to *8.8.8.8*.
 - d. Set *Participants* to *All SD-WAN Members*.
 - e. Enable *SLA Target* and leave the default values.
 - f. Click *OK*.
9. Create SD-WAN rules as needed. The SLA health check can be used to determine when the ISP connections are in or out of SLA, and to failover accordingly.

SD-WAN configuration portability

When configuring SD-WAN, adding interfaces to members is optional.

This allows the SD-WAN to be configured without associating any interfaces to SD-WAN members. It also allows a configuration to be copied directly from one device to another, without requiring the devices to have interfaces with the same names.

After the configuration is created, add interfaces to the members make it functional.

Example 1

In this example, we create a template with two SD-WAN members configured without assigned interfaces that are used in a performance SLA and SD-WAN rule. The template can be used to configure new devices, as in [Example 2 on page 996](#). Interfaces are then assigned to the members, and the configuration becomes active.

To create the SD-WAN members in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
2. Leave all the settings set to their default values and click *OK*.

3. Repeat the above steps to create a second member.
The empty members are listed on the *SD-WAN Zones* tab.

SD-WAN Zones SD-WAN Rules Performance SLAs

Bandwidth Volume Sessions

No results

No results

+ Create New Edit Delete

	Interfaces	Gateway	IPv6 Gateway	Cost	Download	Upload
	virtual-wan-link					
	Member 1	0.0.0.0	::	0		
	Member 2	0.0.0.0	::	0		

Updated: 16:08:17

The members are disabled until interfaces are configured, but can still be used in performance SLAs and SD-WAN rules.

To create a performance SLA in the GUI:

1. Go to *Network > SD-WAN* and select the *Performance SLAs* tab.
2. Click *Create New*.
3. Configure the performance SLA, specifying the empty members as participants.

New Performance SLA

Name: office

IP Version: IPv4 IPv6

4. Click *OK*.

To create an SD-WAN rule in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Configure the rule, adding both members to the *Interface preference* field:

Priority Rule

Name: Office365

IP Version: IPv4 IPv6

Source

Source address: +

User group: +

Destination

Address: +

Internet Service: +

Application: Microsoft.Office.365

Outgoing Interfaces

Select a strategy for how outgoing interfaces will be chosen.

☐ Manual
Manually assign outgoing interfaces.

☐ Best Quality
The interface with the best measured performance is selected.

☒ **Lowest Cost (SLA)**
The interface that meets SLA targets is selected. When there is a tie, the interface with the lowest assigned cost is selected.

☐ Maximize Bandwidth (SLA)
Traffic is load balanced among interfaces that meet SLA targets.

Interface preference: Member 1 Member 2

Zone preference: +

Required SLA target: office

Forward DSCP: ☐

Reverse DSCP: ☐

Status: ☒ Enable ☐ Disable

Documentation

- Online Help
- Video Tutorials

OK Cancel

4. Click *OK*.
5. Repeat the above steps to assign an interface to the second member.

To configure the SD-WAN in the CLI:**1. Create SD-WAN members:**

```
config system sdwan
    set status enable
    config members
        edit 1
        next
        edit 2
        next
    end
end
```

2. Create a health check (performance SLA):

```
config system sdwan
    config health-check
        edit "office"
            set server "office365.com"
            set protocol http
            set sla-fail-log-period 300
            set sla-pass-log-period 300
            set members 2 1
            config sla
                edit 1
                    set latency-threshold 300
                    set jitter-threshold 200
                next
                edit 2
                    set link-cost-factor latency
                    set latency-threshold 20
                next
            end
        next
    end
end
```

3. Create a service (rule):

```
config system sdwan
    config service
        edit 3
            set name "Office365"
            set mode sla
            set internet-service enable
            set internet-service-app-ctrl 33182
            config sla
                edit "office"
                    set id 2
                next
            end
            set priority-members 1 2
        next
    end
end
```

The SD-WAN configuration can now be used in as a template for new spokes, as in [Example 2 on page 996](#).

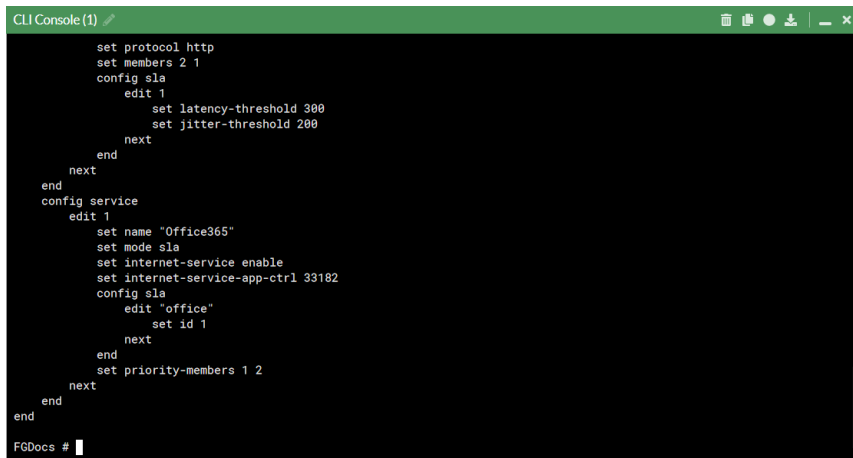

Example 2

In this example, the configuration from [Example 1](#) is copied onto a new FortiGate.

Using the CLI console and the GUI

To copy the SD-WAN configuration from the original FortiGate:

1. Optionally, change the console screen paging setting. See [Screen paging on page 47](#) for details.
2. Open the CLI console.
3. If necessary, click *Clear console* to empty the console.
4. Enter the following command:
`show system sdwan`
5. Either click *Download* and open the file in a text editor, or click *Copy to clipboard* and paste the content into a text editor.

```

CLI Console (1)
set protocol http
set members 2 1
config sla
  edit 1
    set latency-threshold 300
    set jitter-threshold 200
  next
end
next
end
config service
  edit 1
    set name "Office365"
    set mode sla
    set internet-service enable
    set internet-service-app-ctrl 33182
    config sla
      edit "office"
        set id 1
      next
    end
    set priority-members 1 2
  next
end
end
FGDocs #

```

6. Edit the CLI configuration as necessary. For example, the first line that shows the `show` command should be deleted, and the default health checks can be removed.
7. If required, save the CLI configuration as a text file.

To paste the SD-WAN configuration onto a new FortiGate:

1. Copy the SD-WAN configuration from the text editor.
2. On the new FortiGate, open the CLI console.
3. Press `Ctrl + v` to paste the CLI commands.
4. In necessary, press `Enter` to apply the last `end` command.
The SD-WAN configuration is copied to the new FortiGate.
If the interfaces do not exist, the SD-WAN members are created without interfaces, and are disabled until interfaces are configured.

To assign interfaces to the SD-WAN members:

1. Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab.
2. Edit the first member
3. Set *Interface* to an actual interface.

4. Click *OK*.
5. Repeat the above steps to assign an interface to the second member.

Using a terminal emulator

The following instructions use [PuTTY](#). The steps may vary in other terminal emulators.

To copy the SD-WAN configuration from the original FortiGate:

1. Connect to the FortiGate. See [Connecting to the CLI on page 39](#) for details.
2. Enter the following command:

```
show system sdwan
```
3. Select the output, press *Ctrl + c* to copy it, and then paste it into a text editor.
4. Edit the CLI configuration as necessary. For example, the default health checks can be removed.
5. If required, save the CLI configuration as a text file.

To paste the SD-WAN configuration onto a new FortiGate:

1. Connect to the new FortiGate. See [Connecting to the CLI on page 39](#) for details.
2. Copy the SD-WAN configuration from the text editor.
3. Right-click to paste the SD-WAN configuration.
4. In necessary, press *Enter* to apply the last `end` command.

The SD-WAN configuration is copied to the new FortiGate.

If the interfaces do not exist, the SD-WAN members are created without interfaces, and are disabled until interfaces are configured.

SD-WAN segmentation over a single overlay

SD-WAN, VPN, and BGP configurations support L3 VPN segmentation over a single overlay. In these configurations, a hub and spoke SD-WAN deployment requires that branch sites, or spokes, are able to accommodate multiple companies or departments, and each company's subnet is separated by a different VRF. A subnet on one VRF cannot communicate with a subnet on another VRF between different branches, but can communicate with the same VRF.

SD-WAN options

VRF-aware SD-WAN health checks

SD-WAN on the originating spoke can tag the health check probes with the correct VRF when transmitting to a multi-VRF tunnel. The hub can then forward the probes to the correct health check server in the same VRF as the hub. The IP version (`addr-mode`) can be either IPv4 or IPv6.

```
config system sdwan
  config health-check
    edit <name>
      set vrf <vrf id>
      set source <address>
    next
  end
end
```

vrf <vrf id>	Virtual Routing Forwarding ID.
source <address>	Source IP address used in the health-check packet to the server.

Overlay stickiness

When a hub has multiple overlays, traffic received on one overlay should egress on the same overlay when possible. The `service-sla-tie-break` option ensures overlay stickiness. In SD-WAN service rules, options are available to ensure that traffic received in a zone stays in that zone.

```
config system sdwan
    config zone
        edit <name>
            set service-sla-tie-break input-device
        next
    end
    config service
        edit <id>
            set input-zone <zone>
            set tie-break input-device
        next
    end
end
```

service-sla-tie-break input-device	Members that meet the SLA are selected by matching the input device.
input-zone <zone>	Source input-zone name.
tie-break input-device	Members that meet the SLA are selected by matching the input device.

IPsec options

Configurable rate limit for shortcut offers sent by the hub

By default, the hub sends a shortcut offer to a spoke every five seconds. If the hub continues to send offers that keep failing, and there are a large number of spokes, this can cause a high load on the hub. This setting makes the interval between shortcut offers configurable.

```
config vpn ipsec phase1-interface
    edit <name>
        set auto-discovery-offer-interval <interval>
    next
end
```

auto-discovery-offer- interval <interval>	Interval between shortcut offer messages, in seconds (1 - 300, default = 5).
--	--

Segmentation over a single overlay

Segmentation requires that VRF info is encapsulated within the IPsec VPN tunnel. This setting enables multi-VRF IPSEC tunnels.

```

config vpn ipsec phase1-interface
    edit <name>
        set encapsulation vpn-id-ipip
    next
end

```

encapsulation vpn-id-ipip VPN ID with IPIP encapsulation.

VPN configuration for BGP

The role of a VRF can be specified, along with other VRF details. Up to 252 VRFs can be configured per VDOM for any device.

```

config router bgp
    config vrf
        edit <vrf>
            set role {standalone | ce | pe}
            set rd <string>
            set export-rt <route_target>
            set import-rt <route_target>
            set import-route-map <route_map>
            config leak-target
                edit <vrf>
                    set route-map <route-map>
                    set interface <interface>
                next
            end
        next
    end
end

```

role {standalone ce pe}	VRF role: standalone, customer edge (CE), or provider edge (PE).
rd <string>	Route Distinguisher: AA AA:NN. This option is only available when the role is CE.
export-rt <route_target>	List of export route target. This option is only available when the role is CE.
import-rt <route_target>	List of import route target. This option is only available when the role is CE.
import-route-map <route_map>	Import route map. This option is only available when the role is CE.
route-map <route-map>	Route map of VRF leaking.
interface <interface>	Interface that is used to leak routes to the target VRF.

In FortiOS 7.0, config vrf was config vrf-leak, and config leak-target was config target.

Display BGP routes by VRF and neighbor

```
# diagnose ip router bgp set-filter vrf <vrf>
# diagnose ip router bgp set-filter neighbor <neighbor address>
# diagnose ip router bgp set-filter reset
# execute router clear bgp vpnv4 unicast soft {in | out}
# get router info filter show
# get router info filter vrf {vrf | all}
```

Examples

In example 1, multiple companies (or departments of a company) share the ADVPN. Company A and company B each have two branches in two different locations. Company A's branches (A-1 and A-2) can talk to each other using the VPN shortcut, but not to company B's branches (B-1 and B-2). Likewise, company B's branches can talk to each other using the VPN shortcut, but not to company A's branches. Traffic can share the tunnels and shortcuts, but cannot be mixed up.

[Example 2](#) shows that performance SLA health checks can be sent from a spoke's VRF to the loopback on the hub that is in the same VRF.

[Example 3](#) shows that when traffic is ingress on the hub on one overlay, it will preferably egress on the same overlay.

Example 1

In this example, two spokes each have two tunnels to the hub.

- Each spoke has two VRFs behind it that can use the same IP address or subnets.
- The computers in VRF1 behind spoke 1 can talk to the computers in VRF1 behind spoke 2, but not to any of the computers in the VRF2s behind either spoke.
- The computers in VRF2 behind spoke 1 can talk to the computers in VRF2 behind spoke 2, but not to any of the computers in the VRF1s behind either spoke.

To configure the hub:

```
config router bgp
  set as 65505
  set router-id 11.11.11.11
  set ibgp-multipath enable
  set additional-path enable
  set additional-path-vpnv4 enable
  set cluster-id 11.12.13.14
  set additional-path-select 3
  config neighbor-group
    edit "gr1"
      set capability-graceful-restart enable
      set capability-default-originate enable
      set next-hop-self-rr enable
      set soft-reconfiguration-vpnv4 enable
      set remote-as 65505
      set additional-path both
      set additional-path-vpnv4 both
      set adv-additional-path 3
      set route-reflector-client enable
      set route-reflector-client-vpnv4 enable
    next
    edit "gr2"
      set capability-graceful-restart enable
      set capability-default-originate enable
      set next-hop-self-rr enable
      set soft-reconfiguration-vpnv4 enable
      set remote-as 65505
      set additional-path both
      set additional-path-vpnv4 both
      set adv-additional-path 3
      set route-reflector-client enable
      set route-reflector-client-vpnv4 enable
    next
  end
  config neighbor-range
    edit 1
      set prefix 10.10.100.0 255.255.255.0

To test the configuration on shortcut 1:

1. From VRF1 of spoke 1 ping VRF1 of spoke 2 and from VRF2 of spoke 1 ping VRF2 spoke 2. Both VRF1 and VRF2 source and destination IP addresses are the same, so you can see how the traffic is isolated
2. Check sessions on spoke 1:

The output `vd=<vdom ID>:<VRF ID>` indicates that sessions are created in and stay in the corresponding VRFs.

- User at 22.1.1.22 in VRF1 on spoke 1 pings 33.1.1.33 in VRF1 on spoke2.

```
# diagnose sys session list

no_ofld_reason: disabled-by-policy
```

Example 2

In this example, SLA health checks are sent from a spoke's VRF to the loopback on the hub that is in the same VRF.

To configure the health check:

```

config system sdwan
  config health-check
    edit "1"
      set server "11.11.22.11"
      set vrf 1
      set source 22.1.1.2
      set members 1 2
      config sla
        edit 1
          set latency-threshold 200
          set jitter-threshold 50
        next
      end
    next
  end
end

```

To check the health check status:

```

# diagnose sys sdwan health-check status 1
Health Check(1):
Seq(1 vd2-1): state(alive), packet-loss(0.000%) latency(0.023), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1
Seq(2 vd2-2): state(alive), packet-loss(0.000%) latency(0.022), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1

```

Example 3

In this example, when traffic from spoke 1 arrives at the hub on tunnel 1, it will egress the hub on tunnel 1 to go to other spokes. If traffic arrives on tunnel 2, it will egress on tunnel 2, and not tunnel 1.

To configure SD-WAN on the hub:

```

config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
      set service-sla-tie-break input-device
    next
  end
  config members
    edit 1
      set interface "p1"
    next
    edit 2
      set interface "p2"
    next
  end
  config health-check
    edit "1"
      set server "22.1.1.2"
      set members 1 2
      config sla

```

```

        edit 1
        next
    end
next
end
config service
    edit 1
        set mode sla
        set dst "all"
        config sla
            edit "1"
                set id 1
            next
        end
        set priority-members 1 2
        set tie-break input-device
    next
end
end
end

```

To verify that traffic stays in the same overlay on ingress and egress on the hub:

1. Confirm that the SD-WAN service rule has `Tie break` set to `input-device` so that, when SLAs are met on all of the members, traffic prefers to egress on the same member as the input device:

```
# diagnose sys sdwan service
```

```
Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
```

```
Tie break: input-device
```

```
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
```

```
Members(2):
```

```
1: Seq_num(1 p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0), selected
```

```
2: Seq_num(2 p2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0), selected
```

```
Dst address(1):
```

```
0.0.0.0-255.255.255.255
```

2. Use `diagnose sniffer packet` commands to verify that traffic ingress and egress are on the same overlay.

Matching BGP extended community route targets in route maps

BGP extended community route targets can be matched in route maps. This can be applied in a scenario where the BGP route reflector receives routes from many VRFs, and instead of reflecting all routes from all VRFs, users only want to reflect routes based on a specific extended community route target.

To configure the extended community list:

```

config router extcommunity-list
    edit <name>
        set type {standard | expanded}
        config rule
            edit <id>
                set action {deny | permit}
                set type {rt | soo}
                set match <extended_community_specifications>
            end
        end
    end
end

```

```

        set regexp <ordered_list_of_attributes>
    next
end
next
end

```

type {standard expanded}	Set the extended community list type (standard or expanded).
action {deny permit}	Deny or permit route-based operations based on the route's extended community attribute.
type {rt soo}	Set the extended community type: <ul style="list-style-type: none"> • rt: route target • soo: site of origin
match <extended_community_specifications>	Set the extended community specifications for matching a reserved extended community (community number in AA:NN format; use quotation marks complex expressions, "123:234 345:456").
regexp <ordered_list_of_attributes>	Set the ordered list of extended community attributes as a regular expression.

To configure the BGP extended community list in the route map:

```

config router route-map
    edit <name>
        config rule
            edit <id>
                set match-extcommunity <list>
                set match-extcommunity-exact {enable | disable}
            next
        end
    next
end

```

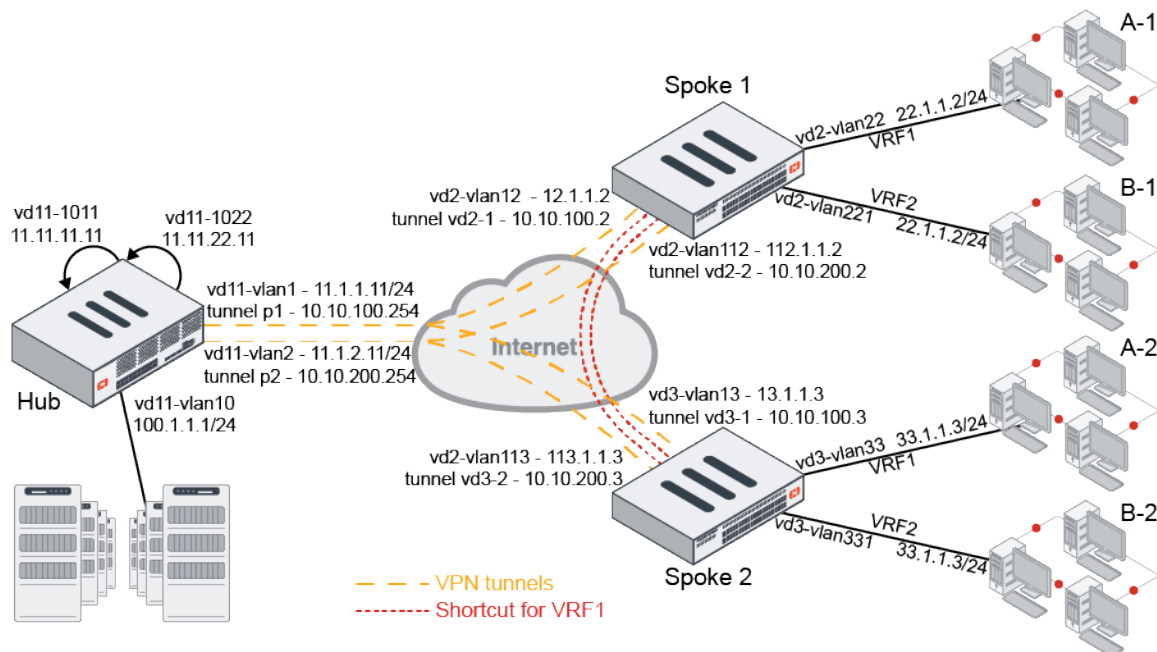

match-extcommunity <list>	Set the BGP extended community list to match to.
match-extcommunity-exact {enable disable}	Enable/disable exact matching of extended communities.

Example

In this example, multiple companies (or departments of a company) share the same hub and spoke VPN infrastructure. Company A and company B each have two branches in two different locations. The goal is for company A's branches (A-1 and A-2) to be able to communicate only with each other over VPN but not with company B's branches. Likewise, company B's branches (B-1 and B-2) can only communicate with each other over VPN but not with company A's. This is accomplished by placing each branch VLAN into their respective VRFs (VRF1 and VRF2), and encapsulating the VRF information within the VPN tunnel. The hub forms BGP peering with its neighbors, spoke 1 and spoke 2, over each IPsec overlay. The hub's BGP route reflector reflects the routes to the corresponding VRFs, allowing each spoke to form ADVPN shortcuts with the other spoke for each VRF.

However, in this scenario, we want A-1 and A-2 to use an ADVPN shortcut, but we do not want B-1 and B-2 to use ADVPN. A route map is configured on the hub to match the desired extended community route target number where only

this route target is permitted, and others are denied. This allows the hub's BGP route reflector to only reflect routes associated with VRF1, allowing the spokes to form an ADVPN shortcut for VRF1. Routes associated with VRF2 are not reflected, and each spoke must route traffic through the hub to reach VRF2 on the other spoke.

Configure the topology by following the instructions of [Example 1](#) in [SD-WAN segmentation over a single overlay on page 997](#). Note that when checking the spoke 1 routes in example 1, there is a VRF2 route:

```
Spoke 1 # get router info routing-table bgp
...
Routing table for VRF=2
B V    33.1.1.0/24 [200/0] via 10.10.100.3 [2] (recursive via vd2-1 tunnel 11.1.1.11),
00:00:20, [1/0]
                [200/0] via 10.10.200.3 [2] (recursive via vd2-2 tunnel 11.1.2.11),
00:00:20, [1/0]
```

The following procedure applies a route map on the hub's BGP configurations to limit route reflection to only routes matching the external community target of 1:1. This external community target corresponds to BGP paths for VRF1 learned from spoke 1 and spoke 2. The external community target of 2:1 corresponds to BGP paths for VRF2. By not explicitly permitting this target (2:1) in the community list and denying everything other than the permitted target (1:1) in the route map, the VRF2 BGP paths are essentially omitted from being reflected to the spokes.

To configure BGP filtering for an extended community route target on the hub:

1. Identify the external community target of VRF1 to be permitted:

```
# get router info bgp network 33.1.1.0/24
VRF 0 BGP routing table entry for 33.1.1.0/24
Paths: (2 available, best #2, table Default-IP-Routing-Table)
  Advertised to non peer-group peers:
    11.1.1.1
  Advertised to peer-groups:
    gr1 gr2
...
VRF 1 BGP routing table entry for 33.1.1.0/24
```

```

Paths: (2 available, best #2, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0 external duplicated
  Local, (Received from a RR-client)
    0.0.0.0 from 10.10.100.3 (3.3.3.3)

  Local, (Received from a RR-client)
    0.0.0.0 from 10.10.200.3 (3.3.3.3)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Extended Community: RT:1:1
      Receive Path ID: 1
      Advertised Path ID: 2
      Last update: Wed Aug 17 10:31:02 2022
VRF 2 BGP routing table entry for 33.1.1.0/24
Paths: (2 available, best #2, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0 external duplicated
  Local, (Received from a RR-client)
    0.0.0.0 from 10.10.100.3 (3.3.3.3)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Extended Community: RT:2:1
      Receive Path ID: 1
      Advertised Path ID: 1
      Last update: Wed Aug 17 10:31:02 2022
  Original VRF 0 external duplicated
  Local, (Received from a RR-client)
    0.0.0.0 from 10.10.200.3 (3.3.3.3)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Extended Community: RT:2:1
      Receive Path ID: 1
      Advertised Path ID: 2
      Last update: Wed Aug 17 10:31:02 2022

```

2. Configure the extended community list:

```

config router extcommunity-list
  edit "extcomm1"
    config rule
      edit 1
        set action permit
        set match "1:1"
        set type rt
      next
    end
  next
end

```

3. Apply the extended community list to the route map:

```

config router route-map
  edit "rmp11"
    config rule

```

```

        edit 1
            set match-extcommunity "extcomm1"
        next
        edit 2
            set action deny
        next
    end
next
end

```

4. Update the related BGP neighbor group settings:

```

config router bgp
    config neighbor-group
        edit "gr1"
            set route-map-out-vpn4 "rmp11"
        next
        edit "gr2"
            set route-map-out-vpn4 "rmp11"
        next
    end
end

```

5. Refresh the routes:

```
# execute router clear bgp all vpnv4 unicast out
```

6. Check the spoke 1 routes. Since the extended community route target is applied, the VFR2 route does not appear in the BGP routing table:

```

# get router info routing-table bgp
Routing table for VRF=0
B*      0.0.0.0/0 [200/0] via 10.10.100.254 (recursive via vd2-1 tunnel 11.1.1.11),
03:47:50, [1/0]
           [200/0] via 10.10.200.254 (recursive via vd2-2 tunnel 11.1.2.11),
03:47:50, [1/0]
B       1.1.1.1/32 [200/0] via 11.1.1.1 [2] (recursive via 12.1.1.1, vd2-vlan12),
03:47:50, [1/0]
B       1.222.222.222/32 [200/0] via 11.1.1.1 [2] (recursive via 12.1.1.1, vd2-vlan12),
03:47:50, [1/0]
B       11.11.11.11/32 [200/0] via 10.10.100.254 (recursive via vd2-1 tunnel 11.1.1.11),
03:47:50, [1/0]
           [200/0] via 10.10.200.254 (recursive via vd2-2 tunnel 11.1.2.11),
03:47:50, [1/0]
B       33.1.1.0/24 [200/0] via 10.10.100.254 [2] (recursive via vd2-1 tunnel
11.1.1.11), 03:47:21, [1/0]
           [200/0] via 10.10.200.254 [2] (recursive via vd2-2 tunnel
11.1.2.11), 03:47:21, [1/0]

Routing table for VRF=1

                                [200/0] via 10.10.200.254 (recursive via vd2-2 tunnel 11.1.2.11),
03:47:50, [1/0]

```

Copying the DSCP value from the session original direction to its reply direction

In an SD-WAN scenario when DSCP tags are used to mark traffic from the spoke to the hub, it is sometimes desirable for the hub to mark the reply traffic with the same DSCP tags. The `diffserv-copy` setting in firewall policy configurations allows the DSCP tag to be copied to the reply direction.

```

config firewall policy
    edit <id>
        set diffserv-copy {enable | disable}
    next
end

```

Example

The use cases in this example are for a hub and spoke SD-WAN deployment. Traffic from the spoke (either real traffic or SLA health check probes) can be marked with a certain DSCP tag when leaving the spoke. QoS may be applied by an upstream device based on the DSCP tag. When the traffic arrives on the hub, the hub may also want to mark the reply traffic to the spoke with the same DSCP tag. This would allow QoS to be applied to the traffic in the reply direction as well, which is traffic in the hub to spoke direction associated with the same session in the spoke to hub direction.

While this topology simplifies the SD-WAN deployment into a single hub and spoke, this feature applies to the following configurations:

- Multiple spokes (branch sites)
- One or more hubs (data center sites)
- Multiple overlays connecting spokes to hubs
- SD-WAN configured on spokes to pick the best overlay

Use case 1: typical forwarding traffic

Traffic originates from the spoke and is destined for a server behind the hub. The spoke marks the traffic with a DSCP tag of 101010. This is done by enabling `diffserv-forward` on the spoke firewall policy. It can also be accomplished by enabling `dscp-forward` in an SD-WAN rule.

The hub allows the traffic in through a firewall policy. By enabling `diffserv-copy` on the firewall policy, it will mark the reply traffic on the corresponding sessions with the same DSCP tag in which it came.

To configure the FortiGates:**1. Configure the firewall policy on the spoke (FortiGate A):**

```
config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "virtual-wan-link"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set srcaddr6 "all6"
    set dstaddr6 "all6"
    set schedule "always"
    set service "ALL"
    set logtraffic all
    set nat enable
    set diffserv-forward enable
    set diffservcode-forward 101010
  next
end
```

2. Configure the firewall policy on the hub (FortiGate B):

```
config firewall policy
  edit 3
    set srcintf "virtual-wan-link"
    set dstintf "wan1"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set srcaddr6 "all"
    set dstaddr6 "all"
    set schedule "always"
    set service "ALL"
    set logtraffic all
    set auto-asic-offload disable
    set nat enable
    set diffserv-copy enable
  next
end
```

To test the configuration:

1. Generate some forwarding traffic.
2. Verify that the session's `tos` value from the original direction is applied to the reply direction:

```
# diagnose sys session filter policy 3
# diagnose sys session filter dst 172.16.200.55
# diagnose sys session list

session info: proto=1 proto_state=00 duration=35 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
```

```

state=log may_dirty f00
statistic(bytes/packets/allow_err): org=3024/36/1 reply=3024/36/1 tuples=2
tx speed(Bps/kbps): 82/0 rx speed(Bps/kbps): 82/0
origin->sink: org pre->post, reply pre->post dev=20->17/17->20 gwy=172.16.200.55/10.2.2.1
hook=post dir=org act=snat 10.2.2.1:25290->172.16.200.55:8(172.16.200.2:25290)
hook=pre dir=reply act=dnat 172.16.200.55:25290->172.16.200.2:0(10.2.2.1:25290)
misc=0 policy_id=3 pol_uuid_idx=1097 auth_info=0 chk_client_info=0 vd=3
serial=0000a018 tos=6a/6a app_list=0 app=0 url_cat=0
rpd_b_link_id=00000000 ngfwid=n/a
npu_state=0x4000001 no_offload
no_ofld_reason: disabled-by-policy
total session 1

```

Use case 2: local-in traffic destined to a loopback interface

SLA health checks from the spoke are destined for a loopback interface on the hub. The health check is marked with a DSCP tag of 000001 by the spoke. When the hub receives the probes to its loopback, it will mark the replies with the same DSCP tags in which it came.

To configure the FortiGates:

1. Configure the health check on the spoke (FortiGate A):

```

config system sdwan
    config health-check
        edit "ping"
            set server "1.1.1.1"
            set diffservcode 000001
            set members 0
        next
    end
end

```

2. Configure the loopback interface on the hub (FortiGate B):

```

config system interface
    edit "loopback"
        set vdom "vdom1"
        set ip 1.1.1.1 255.255.255.255
        set allowaccess ping https ssh http telnet
        set type loopback
        set role lan
        set snmp-index 35
    next
end

```

3. Configure the firewall policy on the hub:

```

config firewall policy
    edit 1
        set srcintf "virtual-wan-link"
        set dstintf "loopback"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
    end
end

```

```

        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set nat enable
        set diffserv-copy enable
    next
end

```

To test the configuration:

1. Generate some local-in traffic.
2. Verify that the session's `tos` value from the original direction is applied to the reply direction:

```

# diagnose sys session list

session info: proto=1 proto_state=00 duration=1 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/0
state=log local may_dirty
statistic(bytes/packets/allow_err): org=80/2/1 reply=80/2/1 tuples=2
tx speed(Bps/kbps): 0/0 rx speed(Bps/kbps): 0/0
origin->sink: org pre->in, reply out->post dev=20->42/42->20 gwy=1.1.1.1/0.0.0.0
hook=pre dir=org act=noop 10.2.2.1:15->1.1.1.1:8(0.0.0.0:0)
hook=post dir=reply act=noop 1.1.1.1:15->10.2.2.1:0(0.0.0.0:0)
misc=0 policy_id=1 pol_uuid_idx=0 auth_info=0 chk_client_info=0 vd=3
serial=0001a846 tos=41/41 app_list=0 app=0 url_cat=0
rpd_b_link_id=00000000 ngfwid=n/a
npu_state=0x0000001 no_offload
no_ofld_reason: local disabled-by-policy
total session 1

```

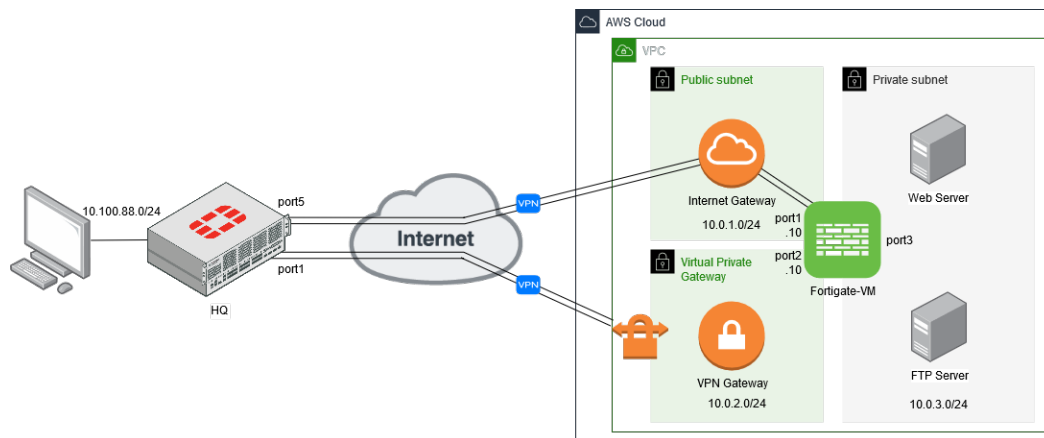

Capture packets can also be used verify that the DSCP value from the original direction is applied to the reply direction.

SD-WAN cloud on-ramp

In this example, you configure a connection to a new cloud deployment that has some remote servers. SD-WAN is used to steer traffic through the required overlay tunnel.

The on-premise FortiGate has two internet connections, each with a single VPN connection. The two VPN gateways are configured on the cloud for redundancy, one terminating at the FortiGate-VM, and the other at the native AWS VPN Gateway.

This example uses AWS as the Infrastructure as a Service (IaaS) provider, but the same configuration can also apply to other services. A full mesh VPN setup is not shown, but can be added later if required.

To connect to the servers that are behind the cloud FortiGate-VM, virtual IP addresses (VIPs) are configured on port2 to map to the servers:

- VPN traffic terminating on port1 is routed to the VIP on port2 to access the web servers.
- VPN traffic terminating on the VPN gateway accesses the VIPs on port2 directly.

There are four major steps to configure this setup:

1. [Configuring the VPN overlay between the HQ FortiGate and cloud FortiGate-VM on page 1021](#)
2. [Configuring the VPN overlay between the HQ FortiGate and AWS native VPN gateway on page 1026](#)
3. [Configuring the VIP to access the remote servers on page 1029](#)
4. [Configuring the SD-WAN to steer traffic between the overlays on page 1032](#)

After the configuration is complete, verify the traffic to ensure that the configuration is working as expected, see [Verifying the traffic on page 1036](#).

Configuring the VPN overlay between the HQ FortiGate and cloud FortiGate-VM

Configure the cloud FortiGate-VM

To create an address for the VPN gateway:

1. Go to *Policy & Objects > Addresses* and click *Create New > Address*.
2. Set *Name* to *local_subnet_10_0_2_0*.
3. Set *IP/Netmask* to *10.0.2.0/24*.

4. Click **OK**.

To configure a custom IPsec VPN:

1. Go to *VPN > IPsec Wizard*.
2. Set *Name* to *Core_Dialup*.
3. Set *Template type* to *Custom*.

VPN Creation Wizard

VPN Setup

Name: Core_Dialup

Template type: Site to Site | Hub-and-Spoke | Remote Access | **Custom**

< Back Next > Cancel

4. Click *Next*.
5. Configure *Network* settings:

Remote Gateway	Dialup User
Interface	port1
NAT Traversal	Enable

6. Configure *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	Enter the pre-shared key.
Version	1
Mode	Aggressive This setting allows the peer ID to be specified.
Accept Types	Specific peer ID
Peer ID	laaS The other end of the tunnel needs to have its local ID set to laaS.

New VPN Tunnel

Authentication

Method: Pre-shared Key

Pre-shared Key: [masked]

IKE

Version: 1 2

IPsec VPNs

Guides

- IPsec VPN Cookbook Recipes
- VPN Setup on FortiClient
- Configuring an IPsec VPN Connection

Documentation

- Online Help
- Video Tutorials

7. Leave the default *Phase 1 Proposal* settings and disable *XAUTH*.

8. Configure the *Phase 2 Selector* settings:

Name	Ent_Core
Local Address	Named Address - <i>local_subnet_10_0_2_0</i>
Remote Address	Named Address - <i>all</i> This setting allows traffic originating from both the remote subnet 10.100.88.0 and the health checks from the VPN interface on the remote FortiGate. For increased security, each subnet can be specified individually.

9. Click OK.

To configure remote and local tunnel IP addresses:

1. Go to *Network > Interfaces* and edit the *Core_Dialup* interface under *port1*.
2. Set *IP* to *172.16.200.1*.
3. Set *Remote IP/Netmask* to *172.16.200.2 255.255.255.0*. This is where remote health check traffic will come from.
4. Enable *Administrative access* for *HTTPS*, *PING*, and *SSH*.

The screenshot shows the 'Edit Interface' configuration for 'Core_Dialup'. The 'Name' is 'Core_Dialup' and the 'Interface' is 'port1'. The 'Address' section shows 'Addressing mode' set to 'Manual', 'IP' set to '172.16.200.1', and 'Remote IP/Netmask' set to '172.16.200.2 255.255.255.0'. The 'Administrative Access' section has checkboxes for 'HTTPS', 'SSH', 'PING', 'SNMP', 'RADIUS Accounting', 'Security Fabric Connection', 'FMG-Access', and 'FTM'. The 'DHCP Server' option is disabled. On the right, the 'FortiGate' status is 'Up' and there are links for 'API Preview', 'References', 'Edit in CLI', 'Documentation', 'Online Help', and 'Video Tutorials'.

5. Click OK.

To configure a route to the remote subnet through the tunnel:

1. Go to *Network > Static Routes* and click *Create New*.
2. Set *Destination* to *Subnet* and enter the IP address and netmask: *10.100.88.0/255.255.255.0*.
3. Set *Interface* to *Core_Dialup*.

The screenshot shows the 'New Static Route' configuration page. The 'Destination' is set to 'Subnet' with the IP address and netmask '10.100.88.0/255.255.255.0'. The 'Interface' is set to 'Core_Dialup'. The 'Administrative Distance' is set to '10'. The 'Status' is set to 'Enabled'. There are links for 'API Preview', 'Documentation', 'Online Help', and 'Video Tutorials' on the right.

4. Click OK.

To configure a firewall policy to allow traffic from the tunnel to port2:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following:

Name	Core_Dialup-to-port2
Incoming Interface	Core_Dialup
Outgoing Interface	port2
Source	all
Destination	local_subnet_10_0_2_0
Schedule	always
Service	ALL
Action	ACCEPT

3. Configure the remaining settings as required.
4. Click **OK**.

Configure the HQ FortiGate

To create an address for the VPN gateway:

1. Go to *Policy & Objects > Addresses* and click *Create New > Address*.
2. Set *Name* to *remote_subnet_10_0_2_0*.
3. Set *IP/Netmask* to *10.0.2.0/24*.
4. Click **OK**.

To configure a custom IPsec VPN:

1. Go to *VPN > IPsec Wizard*.
2. Set *Name* to *FGT_AWS_Tun*.
3. Set *Template type* to *Custom*.
4. Click **Next**.
5. Configure *Network* settings:

Remote Gateway	Static IP Address
IP Address	100.21.29.17
Interface	port5
NAT Traversal	Enable

6. Configure *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	Enter the pre-shared key.
Version	1
Mode	Aggressive This setting allows the peer ID to be specified.
Accept Types	Any peer ID

7. Leave the default *Phase 1 Proposal* settings, except set *Local ID* to *laaS*.

8. Disable *XAUTH*.

9. Configure the *Phase 2 Selector* settings:

Name	FGT_AWS_Tun
Local Address	Named Address - <i>all</i> This setting allows traffic originating from both the local subnet 10.100.88.0 and the health checks from the VPN interface. For increased security, each subnet can be specified individually.
Remote Address	Named Address - <i>remote_subnet_10_0_2_0</i>

10. Click *OK*.

To configure local and remote tunnel IP addresses:

1. Go to *Network > Interfaces* and edit the *FGT_AWS_Tun* interface under *port5*.
2. Set *IP* to *172.16.200.2*.
3. Set *Remote IP/Netmask* to *172.16.200.1 255.255.255.0*.
4. Enable *Administrative access* for *HTTPS*, *PING*, and *SSH*.
5. Click *OK*.

Routing is defined when creating the SD-WAN interface. The firewall policy is created after the SD-WAN interface is defined.

Configuring the VPN overlay between the HQ FortiGate and AWS native VPN gateway

This example uses static routing. It is assumed that the AWS VPN Gateway is already configured, and that proper routing is applied on the corresponding subnet.

Verify the AWS configuration

See [Creating routing tables and associate subnets](#) in the [AWS Administration Guide](#) for configuration details.

To check the AWS configuration:

1. Go to *Virtual Private Network (VPN) > Customer Gateways* to confirm that the customer gateway defines the FortiGate IP address as its Gateway IP address, in this case **34.66.121.231**.

2. Go to *Virtual Private Network (VPN) > Virtual Private Gateways* to confirm that a virtual private gateway (VPG) has been created. In this case it is attached to the **Cloud_onRamp** VPC that contains the FortiGate and servers.

3. Go to *Virtual Private Network (VPN) > Site-to-Site VPN Connections* to confirm that site-to-site VPN connections have been created and attached to the customer gateway and virtual private gateway.

If *Routing Options* is *Static*, the IP prefix of the remote subnet on the HQ FortiGate (10.100.88.0) is entered here.

AWS site-to-site VPN always creates two VPN tunnels for redundancy. In this example, only Tunnel 1 is used.

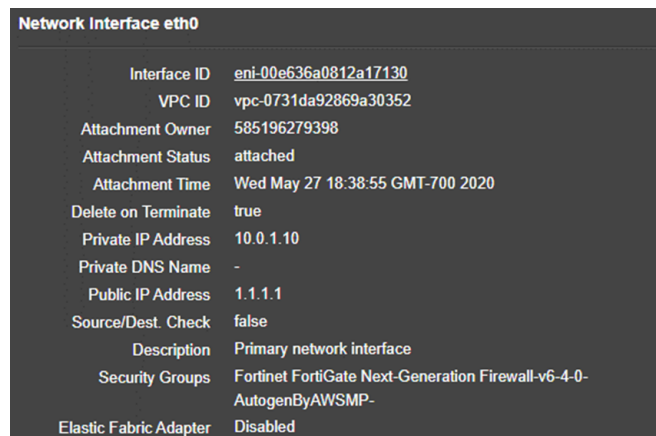

4. Click *Download Configuration* to download the FortiGate's tunnel configurations. The configuration can be referred to when configuring the FortiGate VPN.

5. The new VPG is attached to your VPC, but to successfully route traffic to the VPG, proper routing must be defined. Go to *Virtual Private Cloud > Subnets*, select the *Cloud-OnRamp-VPN*, and select the *Route Table* tab to verify that there are at least two routes to send traffic over the VPG.

- 169.254.0.0/24 defines the tunnel IP address. Health check traffic originating from the FortiGate will come from this IP range.
 - 10.100.0.0/16 defines the remote subnet from the HQ FortiGate.
 - Both routes point to the just created VPG *vgw-04xxxx*.
6. On the cloud FortiGate-VM EC2 instances, ensure that port1 and port2 both have *Source/Dest. Check* set to *false*. This allows the FortiGate to accept and route traffic to and from a different network. If you launched the instance from the AWS marketplace, this setting defaults to *true*.

Configure routing to the VPG on the cloud FortiGate-VM

To configure routing to the VPG on the cloud FortiGate-VM:

1. Go to *Network > Static Routes* and click *Create New*.
2. Set *Destination* to *Subnet* and enter the IP address and netmask: *10.100.88.0/255.255.255.0*.
3. Set *Gateway Address* to *Specify* and enter *10.0.2.1*.

4. Set *Interface* to *port2*.

The new route must have the same *Administrative Distance* as the route that was created for traffic through the *Core_Dialup* tunnel to ensure that both routes are added to the routing table (see [To configure a route to the remote subnet through the tunnel](#)).

The *Gateway Address* is arbitrarily set to 10.0.2.1. The VPG does not have an IP address, but the address defined here allows the FortiGate to route traffic out of port2, while AWS routes the traffic based on its routing table.

5. Click **OK**.

6. Go to *Network > Static Routes* to view the configured static routes:

+ Create New	Edit	Clone	Delete	<input type="text" value="Search"/>	Q
Destination	Gateway IP	Interface	Status	Comments	
IPv4					
10.100.88.0/24	1.0.0.0	Core_Dialup	Enabled		
10.100.88.0/24	10.0.2.1	port2	Enabled		

7. If *Optimal* dashboards is selected, go to *Dashboard > Network* and expand the Routing widget to view the routing table.

If *Comprehensive* dashboards is selected, go to *Dashboard > Routing Monitor* and select *Static & Dynamic* in the widget toolbar to view the routing table:

Network	Gateway IP	Interfaces	Distance	Type
10.100.88.0/24	1.0.0.0	Core_Dialup	10	Static
10.100.88.0/24	10.0.2.1	port2	10	Static
172.16.200.1/32	0.0.0.0	Core_Dialup	0	Connected
10.100.88.0/24	1.0.0.0	Core_Dialup	10	Static

Updated: 04:43:02

Configure IPsec VPN on the HQ FortiGate

To configure a custom IPsec VPN:

- Go to *VPN > IPsec Wizard*.
- Set *Name* to *AWS_VPG*.
- Set *Template type* to *Custom*.
- Click **Next**.
- Configure *Network* settings:

Remote Gateway	Static IP Address
IP Address	34.210.19.225 This address is taken from the downloaded AWS configuration file.
Interface	port1
NAT Traversal	Enable

6. Configure *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	Enter the pre-shared key.
Version	1
Mode	Main

7. Configure the *Phase 1 Proposal* settings using information from the downloaded AWS configuration file.

8. Disable *XAUTH*.
9. Configure the *Phase 2 Selector* settings:

Name	AWS_VPG
Local Address	Named Address - <i>all</i> This setting allows traffic originating from both the local subnet 10.100.88.0 and the health checks from the VPN interface. For increased security, each subnet can be specified individually.
Remote Address	Named Address - <i>remote_subnet_10_0_2_0</i>

10. Click *OK*.

To configure local and remote tunnel IP addresses:

1. Go to *Network > Interfaces* and edit the *AWS_VPG* interface under *port1*.
2. Set *IP* to *169.254.55.154*.
3. Set *Remote IP/Netmask* to *169.254.55.153 255.255.255.0*.
4. Enable *Administrative access* for *HTTPS* and *PING*.
5. Click *OK*.

Routing is defined when creating the SD-WAN interface. The firewall policy is created after the SD-WAN interface is defined.

Configuring the VIP to access the remote servers

VIPs, interface IP addresses, and policies are created on the cloud FortiGate-VM to allow access to the remote servers.

To configure additional private IPs on AWS for the FortiGate VIP:

1. On the FortiGate EC2 instance, edit the *Elastic Network Interface* that corresponds to *port2*. In this example, Network Interface *eth1*.
2. Go to *Actions > Manage IP Addresses*.
3. Add two private IP address in the 10.0.2.0/24 subnet.
These address will be used in the VIPs on the FortiGate. This ensures that traffic to these IP addresses is routed to the FortiGate by AWS.

4. Click **Yes, Update**.

To configure VIPs on the cloud FortiGate-VM:

1. Go to *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP*.
2. Configure the following:

Name	VIP-HTTP
Interface	port2
External IP address/range	10.0.2.20
Map to IPv4 address/range	10.0.3.33

New Virtual IP

VIP type: IPv4

Name: VIP-HTTP

Comments: Write a comment... 0/255

Color: Change

Network

Interface: port2

Type: Static NAT FQDN

External IP address/range: 10.0.2.20

Map to IPv4 address/range: 10.0.3.33

☐ Optional Filters

☐ Port Forwarding

OK Cancel

FortiGate

FortiGate-VM

Additional Information

API Preview

Documentation

Online Help Video Tutorials

3. Click **OK**.

4. Create a second VIP for the FTP server with the following settings:

Name	VIP-FTP
Interface	port2
External IP address/range	10.0.2.21
Map to IPv4 address/range	10.0.3.44

Name	Details	Interfaces	Services	Ref.
IPv4 Virtual IP				
VIP-HTTP	10.0.2.20 → 10.0.3.33	port2		0
VIP-FTP	10.0.2.21 → 10.0.3.44	port2		0

To configure firewall policies to allow traffic from port2 to port3:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following:

Name	To-WebServer
Incoming Interface	port2
Outgoing Interface	port3
Source	all
Destination	VIP-HTTP
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enabled

3. Configure the remaining settings as required.
4. Click *OK*.
5. Create a second policy for the FTP VIP with the following settings:

Name	To-FTP
Incoming Interface	port2
Outgoing Interface	port3
Source	all
Destination	VIP-FTP
Schedule	always
Service	ALL
Action	ACCEPT

NAT

Enabled

6. Click OK.

+ Create New	Edit	Delete	Policy Lookup	Search	<input type="text"/>	Q	Interface Pair View	By Sequence

Configuring the SD-WAN to steer traffic between the overlays

Configure the HQ FortiGate to use two overlay tunnels for SD-WAN, steering HTTPS and HTTP traffic through the FGT_AWS_Tun tunnel, and SSH and FTP through the AWS_VPG tunnel.

1. [Add SD-WAN member interfaces](#)
2. [Configure a route to the remote network](#)
3. [Configure firewall policies](#)
4. [Configure a health check](#)
5. [Configure SD-WAN rules](#)

To add SD-WAN member interfaces:

1. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
2. Set *Interface* to *AWS_VPG* then click *OK*.

OK

Cancel

3. Click *Create New > SD-WAN Member* again.
4. Set *Interface* to *FGT_AWS_Tun*.
5. Set *Gateway* to *172.16.200.1*.

6. Click OK.

To configure a route to the remote network 10.0.2.0/24:

1. Go to *Network > Static Routes* and click *Create New*.
2. Set *Destination* to *Subnet* and enter the IP address and netmask: *10.0.2.0/255.255.255.0*.
3. Set *Interface* to *virtual-wan-link*.

Automatic gateway retrieval: ☐

Destination: **Subnet** | Internet Service

10.0.2.0/255.255.255.0

Interface: virtual-wan-link

Comments: Write a comment... 0/255

Status: **Enabled** | Disabled

OK Cancel

Additional Information: API Preview, Documentation, Online Help, Video Tutorials

4. Click OK.

Individual routes to each tunnel are automatically added to the routing table with the same distance:

To configure firewall policies to allow traffic from the internal subnet to SD-WAN:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following:

Name	ISFW-to-IaaS
------	--------------

Incoming Interface	port3
Outgoing Interface	virtual-wan-link
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enabled

3. Configure the remaining settings as required.
4. Click **OK**.

Once the firewall policies are configured, the VPN tunnels should come up when there is traffic.

To configure a health check to monitor the status of the tunnels:

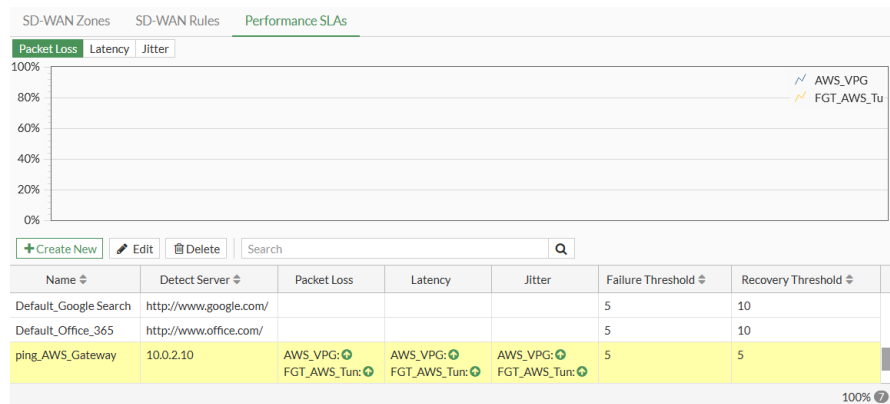

As you are accessing the servers on the 10.0.2.0/24 subnet, it is preferable to use the FortiGate port2 interface as the ping server for detection. This ensures that, if the gateway is not reachable in either tunnel, its routes are brought down and traffic continues on the other tunnel.

1. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Configure the following:

Name	ping_AWS_Gateway
Protocol	Ping
Server	10.0.2.10
Participants	Specify Add AWS_VPG and FGT_AWS_Tun as participants.

The screenshot shows the 'New Performance SLA' configuration window. The 'Name' field is set to 'ping_AWS_Gateway'. The 'Detection Mode' is set to 'Active'. The 'Protocol' is set to 'Ping'. The 'Server' is set to '10.0.2.10'. The 'Participants' section shows 'All SD-WAN Members' and 'Specify' buttons. Below these, 'AWS_VPG' and 'FGT_AWS_Tun' are listed as participants. On the right, there is an 'Additional Information' section with links for 'API Preview', 'Performance SLA Setup Guides', 'Link Monitoring', 'SLA Targets', 'Documentation', 'Online Help', and 'Video Tutorials'. At the bottom, there are 'OK' and 'Cancel' buttons.

3. Click **OK**.

Health check probes originate from the VPN interface's IP address. This is why the phase2 selectors are configured with *Local Address* set to *all*.

To configure SD-WAN rules to steer traffic:

HTTPS and HTTP traffic is steered to the FGT_AWS_Tun tunnel, and SSH and FTP traffic is steered to the AWS_VPG tunnel. The Manual algorithm is used in this example.

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Configure the following:

Name	http-to-FGT_AWS_Tun
Source Address	all
Address	remote_subnet_10_0_2_0
Protocol	TCP
Port range	80 - 80
Outgoing Interfaces	Manual
Interface preference	FGT_AWS_Tun

3. Click *OK*.
4. Create other SD-WAN rules as required:

SD-WAN Zones **SD-WAN Rules** Performance SLAs

+ Create New Edit Clone Delete Search

Verifying the traffic

To verify that pings are sent across the IPsec VPN tunnels

- On the HQ FortiGate, run the following CLI command:

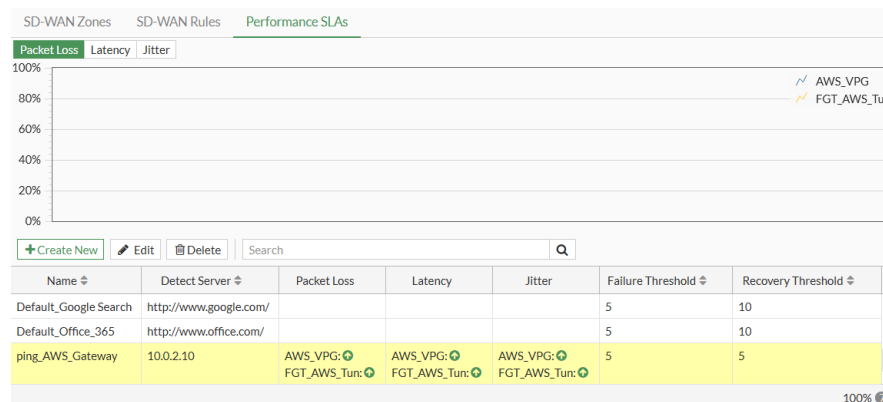

```
# diagnose sniffer packet any 'host 10.0.2.10' 4 0 1 interfaces=[any]
Using Original Sniffing Mode
interfaces=[any]
filters=[host 10.0.2.10]
pcap_snapshot: snaplen raised from 0 to 262144
2021-06-05 11:35:14.822600 AWS_VPG out 169.254.55.154 -> 10.0.2.10: icmp: echo request
2021-06-05 11:35:14.822789 FGT_AWS_Tun out 172.16.200.2 -> 10.0.2.10: icmp: echo request
2021-06-05 11:35:14.877862 FGT_AWS_Tun in 10.0.2.10 -> 172.16.200.2: icmp: echo reply
2021-06-05 11:35:14.878887 AWS_VPG in 10.0.2.10 -> 169.254.55.154: icmp: echo reply
```

- On the cloud FortiGate-VM, run the following CLI command:

```
# diagnose sniffer packet any 'host 10.0.2.10' 4 0 1 interfaces=[any]
Using Original Sniffing Mode
interfaces=[any]
filters=[host 10.0.2.10]
pcap_snapshot: snaplen raised from 0 to 262144
2021-06-05 11:37:57.176329 port2 in 169.254.55.154 -> 10.0.2.10: icmp: echo request
2021-06-05 11:37:57.176363 port2 out 10.0.2.10 -> 169.254.55.154: icmp: echo reply
2021-06-05 11:37:57.176505 Core_Dialup in 172.16.200.2 -> 10.0.2.10: icmp: echo request
2021-06-05 11:37:57.176514 Core_Dialup out 10.0.2.10 -> 172.16.200.2: icmp: echo reply
```

To verify the SLA health checks on the HQ FortiGate:

- Go to *Network > SD-WAN*, select the *Performance SLAs* tab, select *Packet Loss*, and click the *ping_AWS_Gateway* SLA:

- Run the following CLI command:

```
# diagnose sys sdwan health-check
...
Seq(1 AWS_VPG): state(alive), packet-loss(0.000%) latency(56.221), jitter(0.290) sla_map=0x0
Seq(2 FGT_AWS_Tun): state(alive), packet-loss(0.000%) latency(55.039), jitter(0.223) sla_map=0x0
```

To verify service rules:**1. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab:**

SD-WAN Zones SD-WAN Rules Performance SLAs						
+ Create New Edit Clone Delete <input type="text" value="Search"/>

```

To simulate an issue on an overlay VPN tunnel:

On the cloud FortiGate-VM, disable the firewall policy allowing Core_Dialup to port2.

1. Health-checks through the FGT_AWS_Tun tunnel fail:
 - a. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, select *Packet Loss*, and click the *ping_AWS_Gateway SLA*:

- b. Run the following CLI command:

```
# diagnose sys sdwan health-check
...
Seq(1 AWS_VPG): state(alive), packet-loss(0.000%) latency(52.746), jitter(0.713) sla_map=0x0
Seq(2 FGT_AWS_Tun): state(dead), packet-loss(19.000%) sla_map=0x0
```

2. Service rules show that the member is down:

- a. Go to **Network > SD-WAN** and select the **SD-WAN Rules** tab:

ID	Name	Source	Destination	Criteria	Members	Hit Count
IPv4						
1	http-to-FGT_AWS_Tun	all	remote_subnet_10_0_2_0		FGT_AWS_Tun	1
2	ssh-to_AWS_VPG	all	remote_subnet_10_0_2_0		AWS_VPG	2
3	https-to-FGT_AWS_Tun	all	remote_subnet_10_0_2_0		FGT_AWS_Tun	1
4	ftp-to_AWS_VPG	all	FTP-Server		AWS_VPG	2
Implicit						
	sd-wan	all	all	Source IP	any	

- b. Run the following CLI command:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
  Gen(2), TOS(0x0/0x0), Protocol(6: 80->80), Mode(manual)
  Members:
    1: Seq_num(2 FGT_AWS_Tun), dead
  Src address:
    0.0.0.0-255.255.255.255
  Dst address:
    10.0.2.0-10.0.2.255

Service(2): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x0/0x0), Protocol(6: 22->22), Mode(manual)

```

4. Routes to the *FGT_AWS_Tun* tunnel are removed:

- a. If *Optimal* dashboards is selected, go to *Dashboard > Network* and expand the Routing widget to view the routing table.

If *Comprehensive* dashboards is selected, go to *Dashboard > Routing Monitor* and select *Static & Dynamic* in the widget toolbar to view the routing table:

Network	Gateway IP	Interfaces	Distance	IP Version	Type
IPv4 40					
0.0.0.0/0	10.100.64.254	Internet_A (port1)	1	IPv4	Static
0.0.0.0/0	10.100.65.254	Internet_B (port5)	1	IPv4	Static
10.0.2.0/24	169.254.55.153	AWS_VPG	1	IPv4	Static
10.0.10.0/24	0.0.0.0	VPN_A_Tunnel (Branch-HQ-A)	0	IPv4	Connected
10.0.10.1/32	0.0.0.0	VPN_A_Tunnel (Branch-HQ-A)	0	IPv4	Connected

- b. Run the following CLI command:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
S*    0.0.0.0/0 [1/0] via 10.100.64.254, port1
      [1/0] via 10.100.65.254, port5
S     10.0.2.0/24 [1/0] via 169.254.55.153, AWS_VPG
C     10.0.10.0/24 is directly connected, Branch-HQ-A
C     10.0.10.1/32 is directly connected, Branch-HQ-A
...
```

Troubleshooting SD-WAN

The following topics provide instructions on SD-WAN troubleshooting:

- [Tracking SD-WAN sessions on page 1043](#)
- [Understanding SD-WAN related logs on page 1043](#)
- [SD-WAN related diagnose commands on page 1046](#)
- [SD-WAN bandwidth monitoring service on page 1050](#)
- [Using SNMP to monitor health check on page 1053](#)

Tracking SD-WAN sessions

You can check the destination interface in *Dashboard > FortiView Sessions* in order to see which port the traffic is being forwarded to.

The example below demonstrates a source-based load-balance between two SD-WAN members:

- If the source IP address is an *even* number, it will go to *port13*.
- If the source IP address is an *odd* number, it will go to *port12*.

Source	Device	Destination	Application	Protocol	Source Port	Destination Port	Bytes	Packets	Duration (seconds)	Destination Interface
10.2.0.21	00:00:00:00:00:00	50.200.244.000	UDP/123	UDP	123	123	152 B	2		port12
10.2.0.15	00:00:00:00:00:00	95.217.180.000	UDP/123	UDP	123	123	152 B	2	2m 11s	port12
10.2.0.16	00:00:00:00:00:00	4.53.100.000	UDP/123	UDP	123	123	152 B	2	1m 49s	port13
10.1.0.16	00:00:00:00:00:00	90.245.170.000	UDP/123	UDP	123	123	152 B	2	12s	port13
10.100.88.4	00:00:00:00:00:00	209.020.047.000	FortiGuard.Search	UDP	45932	53	0 B	0	56s	port13
10.1.0.11	00:00:00:00:00:00	66.80.78.000	UDP/123	UDP	123	123	152 B	2	2m 1s	port12
10.100.88.4	00:00:00:00:00:00	209.200.147.000	FortiGuard.Search	UDP	44624	53	0 B	0	1m 36s	port13
10.1.0.14	00:00:00:00:00:00	50.205.240.000	UDP/123	UDP	123	123	152 B	2	58s	port13
10.1.0.16	00:00:00:00:00:00	104.105.082.000	UDP/123	UDP	123	123	152 B	2	12s	port13
10.2.0.16	00:00:00:00:00:00	90.217.188.000	UDP/123	UDP	123	123	152 B	2	1m 49s	port13
10.1.0.14	00:00:00:00:00:00	206.209.0.000	UDP/123	UDP	123	123	152 B	2	58s	port13
10.2.0.17	00:00:00:00:00:00	4.50.160.000	UDP/123	UDP	123	123	152 B	2	1m 26s	port12
10.100.88.4	00:00:00:00:00:00	209.220.147.000	FortiGuard.Search	UDP	56358	53	0 B	0	1m 26s	port13
10.100.88.4	00:00:00:00:00:00	96.40.30.000	FortiGuard.Search	UDP	28454	53	0 B	0	2m 44s	port13

10.100.88.4	00:00:00:00:00:00	90.45.30.000	FortiGuard.Search	UDP	27164	53	0 B	0	1m 14s	port13

Understanding SD-WAN related logs

This topic lists the SD-WAN related logs and explains when the logs will be triggered.

Health-check detects a failure:

- When health-check detects a failure, it will record a log:

```
1: date=2021-04-20 time=17:06:31 eventtime=1618963591590008160 tz="-0700"
logid="0100022921" type="event" subtype="system" level="critical" vd="root"
logdesc="Routing information changed" name="test" interface="R150" status="down"
msg="Static route on interface R150 may be removed by health-check test. Route:
(10.100.1.2->10.100.2.22 ping-down) "
```

- When health-check detects a recovery, it will record a log:

```
2: date=2021-04-20 time=17:11:46 eventtime=1618963906950174240 tz="-0700"
logid="0100022921" type="event" subtype="system" level="critical" vd="root"
logdesc="Routing information changed" name="test" interface="R150" status="up"
msg="Static route on interface R150 may be added by health-check test. Route:
(10.100.1.2->10.100.2.22 ping-up) "
```

Health-check has an SLA target and detects SLA qualification changes:

- When health-check has an SLA target and detects SLA changes, and changes to fail:

```
1: date=2021-04-20 time=21:32:33 eventtime=1618979553388763760 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Health Check" healthcheck="test" slatargetid=1 oldvalue="2"
newvalue="1" msg="Number of pass member changed."
```

```
2: date=2021-04-20 time=21:32:33 eventtime=1618979553388751880 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Health Check" healthcheck="test" slatargetid=1 member="1" msg="Member
status changed. Member out-of-sla."
```

- When health-check has an SLA target and detects SLA changes, and changes to pass:

```
1: date=2021-04-20 time=21:38:49 eventtime=1618979929908765200 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Health Check" healthcheck="test" slatargetid=1 oldvalue="1"
newvalue="2" msg="Number of pass member changed."
```

```
2: date=2021-04-20 time=21:38:49 eventtime=1618979929908754060 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="information" vd="root"
logdesc="SDWAN status" eventtype="Health Check" healthcheck="test" slatargetid=1
member="1" msg="Member status changed. Member in sla."
```

SD-WAN calculates a link's session/bandwidth over/under its ratio and stops/resumes traffic:

- When SD-WAN calculates a link's session/bandwidth over its configured ratio and stops forwarding traffic:

```
1: date=2021-04-20 time=21:55:14 eventtime=1618980914728863220 tz="-0700"
logid="0113022924" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
volume status" eventtype="Volume" interface="R160" member="2" msg="Member enters into
conservative status with limited ability to receive new sessions for too much traffic."
```

- When SD-WAN calculates a link's session/bandwidth according to its ratio and resumes forwarding traffic:

```
2: date=2021-04-20 time=22:12:52 eventtime=1618981972698753360 tz="-0700"
logid="0113022924" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
volume status" eventtype="Volume" interface="R160" member="2" msg="Member resume normal
status to receive new sessions for internal adjustment"
```

The SLA mode service rule's SLA qualified member changes:

- When the SLA mode service rule's SLA qualified member changes. In this example R150 fails the SLA check, but is still alive:

```
1: date=2021-04-20 time=22:40:46 eventtime=1618983646428803040 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" seq="2,1" msg="Service
prioritized by SLA will be redirected in sequence order."
```

- When the SLA mode service rule's SLA qualified member changes. In this example R150 changes from fail to pass:

```
2: date=2021-04-20 time=22:41:51 eventtime=1618983711678827920 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" seq="1,2" msg="Service
prioritized by SLA will be redirected in sequence order."
```

The priority mode service rule member's link status changes:

- When priority mode service rule member's link status changes. In this example R150 changes to better than R160, and both are still alive:

```
1: date=2021-04-20 time=22:56:55 eventtime=1618984615708804760 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" metric="packet-loss" seq="2,1"
msg="Service prioritized by performance metric will be redirected in sequence order."
```

- When priority mode service rule member's link status changes. In this example R160 changes to better than R150, and both are still alive:

```
2: date=2021-04-20 time=22:56:58 eventtime=1618984618278852140 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" metric="packet-loss" seq="1,2"
msg="Service prioritized by performance metric will be redirected in sequence order."
```

SD-WAN member is used in service and it fails the health-check:

- When SD-WAN member fails the health-check, it will stop forwarding traffic:

```
1: date=2021-04-20 time=23:04:32 eventtime=1618985072898756700 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" interface="R150" member="1" serviceid=1 service="test"
gateway=10.100.1.1 msg="Member link is unreachable or miss threshold. Stop forwarding
traffic. "
```

- When SD-WAN member passes the health-check again, it will resume forwarding logs:

```
2: date=2021-04-20 time=23:06:08 eventtime=1618985168018789600 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" interface="R150" member="1" serviceid=1 service="test"
gateway=10.100.1.1 msg="Member link is available. Start forwarding traffic. "
```

Load-balance mode service rule's SLA qualified member changes:

- When load-balance mode service rule's SLA qualified member changes. In this example R150 changes to not meet SLA:

```
1: date=2021-04-20 time=23:10:24 eventtime=1618985425048820800 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" member="2 (R160)" msg="Service
will be load balanced among members with available routing."
```

- When load-balance mode service rule's SLA qualified member changes. In this example R150 changes to meet SLA:

```
2: date=2021-04-20 time=23:11:34 eventtime=1618985494478807100 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" member="2 (R160),1 (R150)"
msg="Service will be load balanced among members with available routing."
```

SLA link status logs, generated with interval sla-fail-log-period or sla-pass-log-period:

- When SLA fails, SLA link status logs will be generated with interval sla-fail-log-period:

```
1: date=2021-04-20 time=23:18:10 eventtime=1618985890469018260 tz="-0700"
logid="0113022925" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
SLA information" eventtype="SLA" healthcheck="test" slatargetid=1 interface="R150"
status="up" latency="0.061" jitter="0.004" packetloss="2.000%"
inbandwidthavailable="0kbps" outbandwidthavailable="200.00Mbps"
bibandwidthavailable="200.00Mbps" inbandwidthused="1kbps" outbandwidthused="1kbps"
bibandwidthused="2kbps" slamap="0x0" metric="packetloss" msg="Health Check SLA status.
SLA failed due to being over the performance metric threshold."
```

- When SLA passes, SLA link status logs will be generated with interval `sla-pass-log-period`:

```
2: date=2021-04-20 time=23:18:12 eventtime=1618985892509027220 tz="-0700"
logid="0113022925" type="event" subtype="sdwan" level="information" vd="root"
logdesc="SDWAN SLA information" eventtype="SLA" healthcheck="test" slatargetid=1
interface="R150" status="up" latency="0.060" jitter="0.003" packetloss="0.000%"
inbandwidthavailable="0kbps" outbandwidthavailable="200.00Mbps"
bibandwidthavailable="200.00Mbps" inbandwidthused="1kbps" outbandwidthused="1kbps"
bibandwidthused="2kbps" slamap="0x1" msg="Health Check SLA status."
```

SD-WAN related diagnose commands

This topic lists the SD-WAN related diagnose commands and related output.

To check SD-WAN health-check status:

```
FGT # diagnose sys sdwan health-check
Health Check(server):
Seq(1 R150): state(alive), packet-loss(0.000%) latency(0.110), jitter(0.024) sla_map=0x0
Seq(2 R160): state(alive), packet-loss(0.000%) latency(0.068), jitter(0.009) sla_map=0x0

FGT # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 R150): state(alive), packet-loss(0.000%) latency(0.100), jitter(0.017) sla_map=0x0
Seq(2 R160): state(dead), packet-loss(100.000%) sla_map=0x0

FGT # diagnose sys sdwan health-check google
Health Check(google):
Seq(1 R150): state(alive), packet-loss(0.000%) latency(0.081), jitter(0.019) sla_map=0x0
Seq(2 R160): state(alive), packet-loss(0.000%) latency(0.060), jitter(0.004) sla_map=0x0
```

To check SD-WAN member status:

- When SD-WAN load-balance mode is *source-ip-based/source-dest-ip-based*.

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 0
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 0
```

- When SD-WAN load-balance mode is *weight-based*.

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 33
Session count: 15
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 66
Session count: 1
```

- When SD-WAN load-balance mode is *measured-volume-based*.

- Both members are under volume and still have room:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
```

```
weight: 33
  Config volume ratio: 33, last reading: 218067B, volume room 33MB
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 66
  Config volume ratio: 66, last reading: 202317B, volume room 66MB
```

- Some members are overloaded and some still have room:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 0
  Config volume ratio: 33, last reading: 1287767633B, overload volume 517MB
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 63
  Config volume ratio: 66, last reading: 1686997898B, volume room 63MB
```

- When SD-WAN load balance mode is *usage-based/spillover*.

- When no spillover occurs:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 255
  Egress-spillover-threshold: 400kbit/s, ingress-spillover-threshold: 300kbit/s
  Egress-overbps=0, ingress-overbps=0
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 254
  Egress-spillover-threshold: 0kbit/s, ingress-spillover-threshold: 0kbit/s
  Egress-overbps=0, ingress-overbps=0
```

- When member has reached limit and spillover occurs:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 255
  Egress-spillover-threshold: 400kbit/s, ingress-spillover-threshold: 300kbit/s
  Egress-overbps=1, ingress-overbps=0
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 254
  Egress-spillover-threshold: 0kbit/s, ingress-spillover-threshold: 0kbit/s
  Egress-overbps=0, ingress-overbps=0
```

- You can also use the `diagnose netlink dstmac list` command to check if you are over the limit.

```
FGT # diagnose netlink dstmac list R150
dev=R150 mac=00:00:00:00:00:00 vwl rx_tcp_mss=0 tx_tcp_mss=0 egress_overspill_
threshold=50000 egress_bytes=100982 egress_over_bps=1 ingress_overspill_
threshold=37500 ingress_bytes=40 ingress_over_bps=0 sampler_rate=0 vwl_zone_id=1
intf_qua=0
```

To check SD-WAN service rules status:

- *Manual mode* service rules.

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members(2):
  1: Seq_num(1 R150), alive, selected
  2: Seq_num(2 R160), alive, selected
```

```
Dst address(1):
10.100.21.0-10.100.21.255
```

- **Auto mode service rules.**

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(auto), link-cost-factor(latency),
link-cost-threshold(10), health-check(ping)
Members(2):
1: Seq_num(2 R160), alive, latency: 0.066, selected
2: Seq_num(1 R150), alive, latency: 0.093
Dst address(1):
10.100.21.0-10.100.21.255
```

- **Priority mode service rules.**

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(priority), link-cost-factor
(latency), link-cost-threshold(10), health-check(ping)
Members(2):
1: Seq_num(2 R160), alive, latency: 0.059, selected
2: Seq_num(1 R150), alive, latency: 0.077, selected
Dst address(1):
10.100.21.0-10.100.21.255
```

- **Load-balance mode service rules.**

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance hash-mode=round-robin)
Members(2):
1: Seq_num(1 R150), alive, sla(0x1), gid(2), num of pass(1), selected
2: Seq_num(2 R160), alive, sla(0x1), gid(2), num of pass(1), selected
Dst address(1):
10.100.21.0-10.100.21.255
```

- **SLA mode service rules.**

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Members(2):
1: Seq_num(1 R150), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
2: Seq_num(2 R160), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
Dst address(1):
10.100.21.0-10.100.21.255
```

To check interface logs from the past 15 minutes:

```
FGT (root) # diagnose sys sdwan intf-sla-log R150
Timestamp: Wed Apr 21 16:58:27 2021, used inbandwidth: 655bps, used outbandwidth:

```

To check SLA logs in the past 10 minutes:

```

FGT (root) # diagnose sys sdwan sla-log ping 1
Timestamp: Wed Apr 21 17:10:11 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.079, jitter: 0.023, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:12 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.079, jitter: 0.023, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:12 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.081, jitter: 0.024, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:13 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.081, jitter: 0.025, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:13 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.082, jitter: 0.026, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:14 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.083, jitter: 0.026, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:14 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.084, jitter: 0.026, packet loss: 0.000%.

```

To check Application Control used in SD-WAN and the matching IP addresses:

```

FGT # diagnose sys sdwan internet-service-app-ctrl-list
Gmail(15817 4294836957): 64.233.191.19 6 443 Thu Apr 22 10:10:34 2021
Gmail(15817 4294836957): 142.250.128.83 6 443 Thu Apr 22 10:06:47 2021

YouTube(31077 4294838537): 209.85.200.132 6 443 Thu Apr 22 10:02:03 2021

```

To check the dynamic tunnel status:

```
# diagnose sys link-monitor interface <name> <name>_0
```

For example:

```
# diagnose sys link-monitor interface vd2-2
Interface(vd2-2): state(up, since Tue Jun 15 12:31:28 2021), bandwidth(up:1299bps,
down:0bps), session count(IPv4:2, IPv6:0), tx(2409919 bytes), rx(5292290 bytes), latency
(0.03), jitter(0.00), packet-loss(0.00).

# diagnose sys link-monitor interface vd2-2 vd2-2_0
Interface(vd2-2_0): state(up, since Tue Jun 15 15:21:52 2021), bandwidth(up:640bps,
down:0bps), session count(IPv4:0, IPv6:0), tx(102242 bytes), rx(16388 bytes), latency(0.03),
jitter(0.00), packet-loss(0.00).
```

To check BGP learned routes and determine if they are used in SD-WAN service:

```
FGT # get router info bgp network 10.100.11.0/24
VRF 0 BGP routing table entry for 10.100.11.0/24
Paths: (2 available, best #2, table Default-IP-Routing-Table)
  Advertised to non peer-group peers:
    10.100.1.1
  Original VRF 0
  20 10
    10.100.1.1 from 10.100.1.1 (5.5.5.5)
      Origin incomplete metric 0, route tag 15, localpref 100, valid, external, best
      Community: 30:5
      Advertised Path ID: 2
      Last update: Thu Apr 22 10:27:27 2021

  Original VRF 0
  20 10
    10.100.1.5 from 10.100.1.5 (6.6.6.6)
      Origin incomplete metric 0, route tag 15, localpref 100, valid, external, best
      Community: 30:5
      Advertised Path ID: 1
      Last update: Thu Apr 22 10:25:50 2021

FGT # diagnose sys sdwan route-tag-list
Route-tag: 15, address: v4(1), v6(0)Last write/now: 6543391 6566007
  service(1), last read route-tag 15 at 6543420
Prefix(24): Address list(1):
  10.100.11.0-10.100.11.255 oif: 50 48

FGT # diagnose firewall proute list
list route policy info(vf=root):

```

SD-WAN bandwidth monitoring service

The bandwidth measuring tool is used to detect true upload and download speeds. Bandwidth tests can be run on demand or automated using a script to measure upload and download speeds up to 1 Gbps of throughput. This can be useful when configuring SD-WAN SLA and rules to balance SD-WAN traffic.

The speed test tool requires a valid SD-WAN Bandwidth Monitoring Service license.

The speed test tool is compatible with iperf3.6 with SSL support. It can test the upload bandwidth to the FortiGate Cloud speed test service. It can initiate the server connection and send download requests to the server. The tool can be run up to 10 times a day .

FortiGate downloads the speed test server list. The list expires after 24 hours. One of the speed test servers is selected, based on user input. The speed test runs, testing upload and download speeds. The test results are shown in the command terminal.

To download the speed test server list:

```
# execute speed-test-server download
Download completed.
```

To check the speed test server list:

```
# execute speed-test-server list
AWS_West valid
    Host: 34.210.67.183 5204 fortinet
    Host: 34.210.67.183 5205 fortinet
    Host: 34.210.67.183 5206 fortinet

    Host: 35.197.18.234 5207 fortinet
```

To run the speed test:

You can run the speed test without specifying a server. The system will automatically choose one server from the list and run the speed test.

```
# execute speed-test auto
The license is valid to run speed test.
Speed test quota for 2/1 is 9
current vdom=root

To add a script to run a speed test automatically once every 24 hours:

```

config system auto-script
    edit "speedtest"
        set interval 86400
        set repeat 0
        set start auto
        set script "
execute speed-test-server download
execute speed-test"
    next
end

```

To view the results of the speed test script:

```
execute auto-script result speedtest
```

Using SNMP to monitor health check

You can monitor SD-WAN health check related statistics using SNMP. The MIB file can be downloaded by going to *System > SNMP* and clicking *Download FortiGate MIB File*.

The following OIDs can be monitored:

Name	OID	Description
fgVWLHealthCheckLinkNumber	.1.3.6.1.4.1.12356.101.4.9.1	The number of health check links in fgVWLHealthCheckLinkTable
fgVWLHealthCheckLinkTable	.1.3.6.1.4.1.12356.101.4.9.2	SD-WAN health check statistics table. This table has a dependent expansion relationship with fgVdTable. Only health checks with a configured member link are present in this table.

Name	OID	Description
fgVWLHealthCheckLinkTableEntry	.1.3.6.1.4.1.12356.101.4.9.2.1	SD-WAN health check statistics on a virtual domain.
fgVWLHealthCheckLinkID	.1.3.6.1.4.1.12356.101.4.9.2.1.1	SD-WAN health check link ID. Only health checks with configured member link are present in this table. Virtual-wan-link health check link IDs are only unique within a virtual domain.
fgVWLHealthCheckLinkName	.1.3.6.1.4.1.12356.101.4.9.2.1.2	Health check name.
fgVWLHealthCheckLinkSeq	.1.3.6.1.4.1.12356.101.4.9.2.1.3	SD-WAN member link sequence.
fgVWLHealthCheckLinkState	.1.3.6.1.4.1.12356.101.4.9.2.1.4	Health check state on a specific member link.
fgVWLHealthCheckLinkLatency	.1.3.6.1.4.1.12356.101.4.9.2.1.5	The average latency of a health check on a specific member link within last 30 probes, in float number.
fgVWLHealthCheckLinkJitter	.1.3.6.1.4.1.12356.101.4.9.2.1.6	The average jitter of a health check on a specific member link within last 30 probes, in float number.
fgVWLHealthCheckLinkPacketSend	.1.3.6.1.4.1.12356.101.4.9.2.1.7	The total number of packets sent by a health check on a specific member link.
fgVWLHealthCheckLinkPacketRecv	.1.3.6.1.4.1.12356.101.4.9.2.1.8	The total number of packets received by a health check on a specific member link.
fgVWLHealthCheckLinkPacketLoss	.1.3.6.1.4.1.12356.101.4.9.2.1.9	The packet loss percentage of a health check on a specific member link within last 30 probes, in float number.
fgVWLHealthCheckLinkVdom	.1.3.6.1.4.1.12356.101.4.9.2.1.10	The VDOM that the link monitor entry exists in. This name corresponds to the fgVdEntName used in fgVdTable.
fgVWLHealthCheckLinkBandwidthIn	.1.3.6.1.4.1.12356.101.4.9.2.1.11	The available bandwidth of incoming traffic detected by a health check on a specific member link, in Mbps,

Name	OID	Description
fgVWLHealthCheckLinkBandwidthOut	.1.3.6.1.4.1.12356.101.4.9.2.1.12	The available bandwidth of outgoing traffic detected by a health check on a specific member link, in Mbps.
fgVWLHealthCheckLinkBandwidthBi	.1.3.6.1.4.1.12356.101.4.9.2.1.13	The available bandwidth of bi-direction traffic detected by a health check on a specific member link, in Mbps.
fgVWLHealthCheckLinkIfName	.1.3.6.1.4.1.12356.101.4.9.2.1.14	SD-WAN member interface name.

Example

This example shows a SD-WAN health check configuration and its collected statistics.

To configure the SD-WAN health check:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "port1"
            set gateway 192.168.2.1
        next
        edit 2
            set interface "MPLS"
            set zone "SD-Zone2"
            set cost 20
        next
        edit 3
            set interface "port2"
        next
    end
    config health-check
        edit "pingserver"
            set server "8.8.8.8"
            set sla-fail-log-period 10
            set sla-pass-log-period 20
            set members 2 1 3
            config sla
                edit 1
                    set link-cost-factor jitter packet-loss
                    set packetloss-threshold 2
                next
            end
        next
    end
```

```

end
end

```

The collected statistics:

fgVWLHealthCheckLinkID	.1.3.6.1.4.1.12356.101.4.9.2.1.1	1	2	3
fgVWLHealthCheckLinkName	.1.3.6.1.4.1.12356.101.4.9.2.1.2	pingserver	pingserver	pingserver
fgVWLHealthCheckLinkSeq	.1.3.6.1.4.1.12356.101.4.9.2.1.3	2	1	3
fgVWLHealthCheckLinkState	.1.3.6.1.4.1.12356.101.4.9.2.1.4	0	0	0
fgVWLHealthCheckLinkLatency	.1.3.6.1.4.1.12356.101.4.9.2.1.5	39.302	43.124	44.348
fgVWLHealthCheckLinkJitter	.1.3.6.1.4.1.12356.101.4.9.2.1.6	4.346	3.951	5.05

 - [SSL certificate based authentication on page 1078](#)
 - [Full versus simple ZTNA policies on page 1080](#)
- [ZTNA advanced configurations on page 1087](#)
- [ZTNA configuration examples on page 1101](#)
- [ZTNA troubleshooting and debugging commands on page 1166](#)
- [ZTNA troubleshooting scenarios on page 1171](#)

Zero Trust Network Access introduction

Zero Trust Network Access (ZTNA) is an access control method that uses client device identification, authentication, and Zero Trust tags to provide role-based application access. It gives administrators the flexibility to manage network access for On-net local users and Off-net remote users. Access to applications is granted only after device verification, authenticating the user's identity, authorizing the user, and then performing context based posture checks using Zero Trust tags.

Traditionally, a user and a device have different sets of rules for on-net access and off-net VPN access to company resources. With a distributed workforce and access that spans company networks, data centers, and cloud, managing the rules can become complex. User experience is also affected when multiple VPNs are needed to get to various resources. ZTNA can improve this experience.

ZTNA application gateway and IP/MAC based access control

- ZTNA application gateway allows users to securely access resources through an SSL encrypted access proxy. This simplifies remote access by eliminating the use of VPNs.
- IP/MAC based access control combines IP/MAC with uses ZTNA tags for identification and security posture check to implement role-based zero trust access.

ZTNA telemetry, tags, and policy enforcement

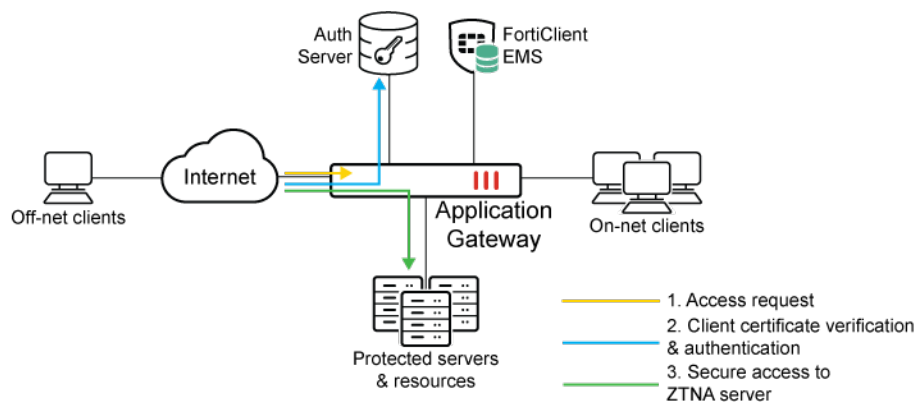

When On-net and Off-net FortiClient endpoints register to FortiClient EMS, device information, log on user information, and security posture are all shared over ZTNA telemetry with the EMS server. Clients also make a certificate signing request to obtain a client certificate from the EMS that is acting as the ZTNA Certificate Authority (CA).

Based on the client information, EMS applies matching Zero Trust tagging rules to tag the clients. These tags, and the client certificate information, are synchronized with the FortiGate in real-time. This allows the FortiGate to verify the client's identity using the client certificate, and grant access based on the ZTNA tags applied in the ZTNA policy.

For more information, see [Establish device identity and trust context with FortiClient EMS on page 1071](#).

Application gateway

The FortiGate application gateway can proxy HTTP, SSH, RDP, SMB, FTP, and other TCP traffic over secure connections with the client. This enables seamless access from the client to the protected servers, without needing to form IPsec or SSL VPN tunnels.

HTTPS access proxy

The FortiGate HTTPS access proxy works as a reverse proxy for the HTTP server. When a client connects to a webpage hosted by the protected server, the address resolves to the FortiGate's access proxy VIP. The FortiGate proxies the

connection and takes steps to authenticate the user. It prompts the user for their certificate on the browser, and verifies this against the ZTNA endpoint record that is synchronized from the EMS. If an authentication scheme, such as SAML authentication, is configured, the client is redirected to a captive portal for sign-on. If this passes, traffic is allowed based on ZTNA policies, and the FortiGate returns the webpage to the client.

For example configurations, see [ZTNA HTTPS access proxy example on page 1102](#), [ZTNA HTTPS access proxy with basic authentication example on page 1112](#), and [ZTNA application gateway with SAML authentication example on page 1132](#).

TCP forwarding access proxy (TFAP)

The TCP forwarding access proxy works as a special type of HTTPS reverse proxy. Instead of proxying traffic to a web server, TCP traffic is tunneled between the client and the access proxy over HTTPS, and forwarded to the protected resource. The FortiClient on the remote endpoint intercepts traffic destined for the protected resources and routes them to the FortiGate proxy gateway. An HTTPS connection is made to the FortiGate's access proxy VIP, where the client certificate is verified and access is granted based on the ZTNA policies. TCP traffic is forwarded from the FortiGate to the protected resource, and an end to end connection is established. To reduce overhead, you can disable access proxy encryption on the client, as some TCP protocols, like RDP, are already secure. The TCP forwarding access proxy supports UTM scanning and deep inspection for HTTP, HTTPS, SMTP, SMTPS, IMAP, IMAPS, POP3, POP3S, SMB, and CIFS.

For an example configuration, see [ZTNA TCP forwarding access proxy example on page 1119](#).

SSH access proxy

The SSH access proxy provides some benefits to proxying SSH connections over TFAP, including allowing SSH deep inspection, performing optional SSH host-key validation, and allowing one time user authentication to authenticate the ZTNA SSH access proxy connection and SSH server connection.

For an example configuration, see [ZTNA SSH access proxy example on page 1125](#).

Basic ZTNA configuration components

The basic components that are required to configure ZTNA application gateway on the FortiGate are:

1. FortiClient EMS fabric connector and ZTNA tags.
2. FortiClient EMS running version 7.0.0 or later or FortiClient EMS Cloud.
3. FortiClient running 7.0.0 or later.
4. ZTNA server
5. ZTNA policy
6. (Optional) User authentication
7. (Optional) HA configurations

For configuration details, see [Basic ZTNA configuration on page 1059](#).

Basic ZTNA configuration

To deploy a ZTNA application gateway, configure the following components on the FortiGate:

1. [Configure a FortiClient EMS connector on page 1060](#)
2. [Configure a ZTNA server on page 1062](#)
3. [Configure a ZTNA policy on page 1065](#)
4. [Optional authentication on page 1068](#)
5. [Optional HA configurations on page 1070](#)

To configure ZTNA in the GUI, go to *System > Feature Visibility* and enable *Zero Trust Network Access*.

Desktop models that are below 100-series have ZTNA settings disabled by default. To configure ZTNA, enable the following:

```
config system global
    set proxy-and-explicit-proxy enable
end
```

Configure a FortiClient EMS connector

To add an on-premise FortiClient EMS server in the GUI:

1. Go to *Security Fabric > Fabric Connectors* and double-click the *FortiClient EMS* card.
2. Set the *Status* to *Enabled*.
3. Enter a name for the connector and the IP address or FQDN of the EMS.
4. Click *OK*.
5. A window appears to verify the EMS server certificate. Click *Accept*.
See [FortiClient EMS](#) for more information.

To add an on-premise FortiClient EMS server in the CLI:

```
config endpoint-control fctems
    edit <name>
        set server <server IP or domain>
    next
end
```

To add FortiClient EMS Cloud in the GUI:

1. Go to *Security Fabric > Fabric Connectors* and double-click the *FortiClient EMS* card.
2. Set the *Status* to *Enabled*.
3. Set the *Type* to *FortiClient EMS Cloud*.
4. Enter a name for the connector.
5. Click *OK*. A window appears to verify the EMS server certificate.
6. Click *Accept*.
See [FortiClient EMS](#) for more information.

To add FortiClient EMS Cloud in the CLI:

```

config endpoint-control fctems
    edit <name>
        set fortinetone-cloud-authentication enable
        set certificate <string>
    next
end

```

ZTNA tags

After the FortiGate connects to the FortiClient EMS, it automatically synchronizes ZTNA tags. ZTNA tags are generated from tagging rules configured on the FortiClient EMS. These tagging rules are based on various posture checks that can be applied on the endpoints. See [Endpoint Posture Check Reference](#).

To view the synchronized ZTNA tags in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Tags* tab.
2. Hover the cursor over a tag name to view more information about the tag, such as its resolved addresses.

View matched endpoints

View resolved addresses

To create a ZTNA tag group in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Tags* tab.
2. Click *Create New Group*.
3. Enter a name for the group and select the group members.

4. Click **OK**.

To view the synchronized ZTNA tags in the CLI:

```
# diagnose firewall dynamic address
# diagnose firewall dynamic list
```

To create a ZTNA tag group in the CLI:

```
config firewall addrgrp
  edit <group name>
    set category ztna-ems-tag
    set member <members>
  next
end
```

Configure a ZTNA server

To configure a ZTNA server, define the access proxy VIP and the real servers that clients will connect to. The access proxy VIP is the FortiGate ZTNA gateway that clients make HTTPS connections to. The service/server mappings define the virtual host matching rules and the real server mappings of the HTTPS requests.

To create a ZTNA server for HTTPS access proxy in the GUI:

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Enter a name for the server.
4. Select an external interface, enter the external IP address, and select the external port that the clients will connect to.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.

6. Add server mapping:

- a. In the *Service/server mapping* table, click *Create New*.
- b. Set *Service* to *HTTPS*.
- c. Set *Virtual Host* to *Any Host* or *Specify*.
 - *Any Host*: Any request that resolves to the access proxy VIP will be mapped to your real servers. For example, if both `www.example1.com` and `www.example2.com` resolve to the VIP, then both requests are mapped to your real servers.
 - *Specify*: Enter the name or IP address of the host that the request must match. For example, if `www.example1.com` is entered as the host, then only requests to `www.example1.com` will match.
- d. Configure the path as needed.

The path can be matched by substring, wildcard, or regular expression. For example, if the virtual host is specified as `www.example1.com`, and the path substring is `map1`, then `www.example1.com/map1` will be matched.

- e. If multiple servers will be configured, enable *Load balancing* and select an algorithm.
- f. Add a server:

- i. In the *Servers* table, click *Create New*.
 - ii. Enter the server IP address and port number.
 - iii. Set the server status.
 - iv. Click *OK*.
 - v. Add more servers as needed.
 - g. Click *OK*.
 - h. Add more server mappings as needed.
7. Click *OK*.

To create a ZTNA server and access proxy VIP in the CLI:**1. Configure an access proxy VIP:**

```
config firewall vip
    edit <name>
        set type access-proxy
        set extip <external IP>
        set extintf <external interface>
        set server-type {https | ssh}
        set extport <external port>
        set ssl-certificate <certificate>
    next
end
```

2. If the virtual host is specified, configure the virtual host:

```
config firewall access-proxy-virtual-host
    edit <auto generated when configured from GUI>
        set ssl-certificate <certificate>
        set host <host name or IP>
        set host-type {sub-string | wildcard}
    next
end
```

3. Configure the server and path mapping:

```
config firewall access-proxy
    edit <name>
        set vip <vip name>
        set client-cert {enable | disable}
        set empty-cert-action {accept | block}
        set log-blocked-traffic {enable | disable}
        config api-gateway
            edit 1
                set url-map <mapped path>
                set service {http | https | tcp-forwarding | samlsp}
                set virtual-host <name of virtual-host if specified>
                set url-map-type {sub-string | wildcard | regex}
            config realservers
                edit 1
                    set addr-type ip
                    set ip <ip of real server>
                    set port <port>
                    set status {active | standby | disable}
                    set health-check {enable | disable}
```

```

        set translate-host {enable | disable}
    next
end
set ldb-method static
set persistence none
set ssl-dh-bits 2048
set ssl-algorithm high
set ssl-min-version tls-1.1
set ssl-max-version tls-1.3
next
end
next
end

```

Configure a ZTNA policy

A ZTNA policy is used to enforce zero trust role based access control by using ZTNA tags or tag groups to verify a device's security posture. A ZTNA policy can also utilize security profiles to protect this traffic.

In earlier versions, ZTNA rules were special proxy policies that controlled access to the ZTNA servers, and they could be configured from the *Policy & Objects > ZTNA > ZTNA Rules* tab. However, on this version and above, these special proxy policies are now configured from *Policy & Objects > Proxy Policy* page.

There are two ways to configure ZTNA rules in the GUI by using a full or simple ZTNA policy:

- Full ZTNA policy: The legacy method for configuring access-proxy policies.
- Simple ZTNA policy: A simplified method for configuring a ZTNA policy using firewall policies. This method covers most functionalities of a Full ZTNA policy, except it cannot control access based on destination interface or real server's destination address.

To configure a simple ZTNA policy in the GUI:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New*.
3. Enter a name for the ZTNA policy.
4. Set *Type* to *ZTNA*.
5. Select an *Incoming Interface* and *Source*.
6. Add the ZTNA tags or tag groups that are allowed access. If multiple tags are included, the matching method is set to *Any* by default.
7. Select the *ZTNA Server*.
8. Select the *Action*.

9. Configure the remaining options as needed.
10. Click OK.

To configure a simple ZTNA policy in the CLI:

```
config firewall policy
  edit 1
    set name <ZTNA policy name>
    set srcintf <interface>
    set dstintf "any"
    set action accept
    set srcaddr "all"
    set dstaddr <access proxy vip>
    set ztna-ems-tag <ZTNA tags>
    set schedule "always"
    set nat enable
  next
end
```

The `dstintf` command cannot be modified.

To configure a full ZTNA policy in the GUI:

1. Go to *System > Feature Visibility*.
2. Under *Security Features*, enabled *Explicit Proxy*.
3. Click *Apply*.
4. Go to *Policy & Objects > Proxy Policy*.

5. Click *Create New*.
6. Enter a name for the rule.
7. Select an *Incoming Interface* and *Source*.
8. Add the ZTNA tags or tag groups that are allowed access. If multiple tags are included, the matching method is set to *Any* by default.
9. Select the *Destination*.
10. Select the *ZTNA Server*.
11. Select the *Action*.

12. Configure the remaining options as needed.
13. Click *OK*.

To configure a full ZTNA policy in the CLI:

```
config firewall proxy-policy
  edit 1
    set name <ZTNA policy name>
    set proxy access-proxy
    set access-proxy <access proxy>
    set srcintf <interface>
    set srcaddr "all"
    set transparent {enable | disable}
    set dstaddr "all"
    set ztna-ems-tag <ZTNA tag(s)>
    set ztna-tags-match-logic {or | and}
    set action accept
    set schedule "always"
    set logtraffic all
    set poolname <ip_pool>
    set utm-status enable
```

```

    set ssl-ssh-profile <inspection profile>
next
end

```

The `transparent` and `poolname` settings cannot be enabled at the same time. Use one setting at a time when configuring ZTNA policies.

Optional authentication

To configure authentication to the access proxy, you must configure an authentication scheme and authentication rule in the GUI or CLI. They are used to authenticate proxy-based policies, similar to configuring authentication for explicit and transparent proxy.

The authentication scheme defines the method of authentication that is applied. For ZTNA, basic HTTP and SAML methods are supported. Each method has additional settings to define the data source to check against. For example, with basic HTTP authentication, a user database can reference an LDAP server, RADIUS server, local database, or other supported authentication servers that the user is authenticated against.

The authentication rule defines the proxy sources and destinations that require authentication, and which authentication scheme to apply. For ZTNA, active authentication method is supported. The active authentication method references a scheme where users are actively prompted for authentication, like with basic authentication.

After the authentication rule triggers the method to authenticate the user, a successful authentication returns the groups that the user belongs to. In the ZTNA policy you can define a user or user group as the allowed source. Only users that match that user or group are allowed through the proxy policy.

To configure a basic authentication scheme in the GUI:

1. Go to *Policy & Objects > Authentication Rules*.
2. Click *Create New > Authentication Scheme*.
3. Enter a name for the scheme.
4. Set the *Method* as *Basic*.
5. Select the *User database* as required.

6. Click **OK**.

To configure a basic authentication scheme in the CLI:

```

config authentication scheme
    edit <name>
        set method basic
    end
end

```

```

        set user-database <auth server>
    next
end

```

To configure an authentication rule in the GUI:

1. Go to *Policy & Objects > Authentication Rules*.
2. Click *Create New > Authentication Rule*.
3. Enter a name for the rule.
4. Select the *Source Address*.
5. Select the *Incoming interface*.
6. Select the *Authentication Scheme*.

The screenshot shows the 'Add New Rule' window in the FortiGate GUI. The 'Name' field is set to 'Basic-rule'. The 'Source Address' field is set to 'all'. The 'Incoming Interface' is set to 'WAN (port3)'. The 'Protocol' is set to 'HTTP'. The 'Authentication Scheme' is set to 'Basic-scheme'. The 'IP-based Authentication' checkbox is checked (Enable). The 'SSO Authentication Scheme' checkbox is unchecked (Disable). The 'Comments' field has a placeholder 'Write a comment...'. The 'Enable This Rule' checkbox is checked (Enable). There are 'OK' and 'Cancel' buttons at the bottom. On the right side, there is an 'Additional Information' section with links for 'API Preview', 'Online Guides', 'Relevant Documentation', 'Video Tutorials', 'Hot Questions at FortiAnswers', and 'Join the Discussion'.

7. Click *OK*.

To configure an authentication rule in the CLI:

```

config authentication rule
    edit <name>
        set status enable
        set protocol http
        set srcintf <interface>
        set srcaddr <address>
        set dstaddr <address>
        set ip-based enable
        set active-auth-method <active auth scheme>
    next
end

```

To apply a user group to a full ZTNA policy in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Edit an existing rule, or click *Create New* to create a new rule.
3. Click in the *Source* field, select the *User* tab, and select the users and user groups that will be allowed access.
4. Configure the remaining settings as required.
5. Click *OK*.

To apply a user group to a full ZTNA policy in the CLI:

```

config firewall proxy-policy
    edit <policy ID>

```

```

set name <ZTNA policy name>
set proxy access-proxy
set access-proxy <access proxy>
set srcintf <interface>
set srcaddr "all"
set dstaddr "all"
set ztna-ems-tag <ZTNA tags>
set ztna-tags-match-logic {or | and}
set action accept
set schedule "always"
set logtraffic all
set groups <user group>
set utm-status enable
set ssl-ssh-profile <inspection profile>
next
end

```

The authentication rule and scheme defines the method used to authenticate users. With basic HTTP authentication, a sign in prompt is shown after the client certificate prompt. After the authentication passes, the returned groups that the user is a member of are checked against the user groups that are defined in the ZTNA policy. If a group matches, then the user is allowed access after passing a posture check.

For basic setup information, see [ZTNA HTTPS access proxy with basic authentication example on page 1112](#).

For advanced setup information, see [ZTNA application gateway with SAML authentication example on page 1132](#) and [ZTNA application gateway with SAML and MFA using FortiAuthenticator example on page 1136](#).

Optional HA configurations

User information and TLS sessions are synchronized between HA members for ZTNA proxy sessions. When a failover occurs, the new primary unit will continue allowing sessions from the logged in users without asking for the client certificate and re-authentication again.

There are no special configurations for HA. Refer to [HA active-passive cluster setup on page 2528](#) and [HA active-active cluster setup on page 2530](#) to configure your HA cluster.

HTTP access proxy vs TCP forwarding access proxy

In an HTTP access proxy connection, there is no configurations needed on the client endpoint. Users can simply access the HTTP website on a browser by entering its URL. For TCP forwarding access proxy, a ZTNA rule must be configured on the FortiClient endpoint. This rule instructs the FortiClient to listen to traffic to the destination address and port, and redirects the traffic to the FortiGate access proxy over HTTPS.

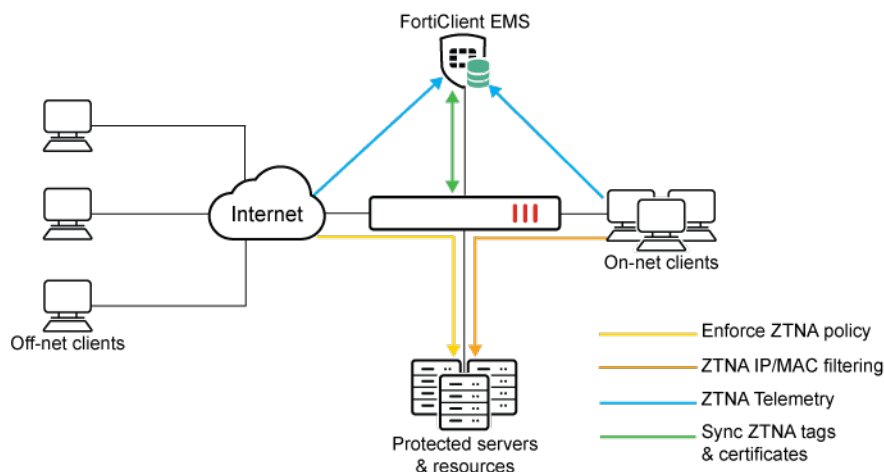

When deciding between using HTTP access proxy or TFAP for accessing web applications, consider the following.

- Use HTTP access proxy when the protected web application address can be resolved by the remote users publicly.
- Use TFAP when the protected application address can only be resolved on the internal network. TCP forwarding rules allow the FortiClient to intercept the request to the destination address and forward them to the application gateway.

For more information, see [ZTNA TCP forwarding access proxy example on page 1119](#).

Establish device identity and trust context with FortiClient EMS

How device identity is established through client certificates, and how device trust context is established between FortiClient, FortiClient EMS, and the FortiGate, are integral to ZTNA.

Device roles

FortiClient

FortiClient endpoints provide the following information to FortiClient EMS when they register to the EMS:

- Device information (network details, operating system, model, and others)
- Logged on user information
- Security posture (On-net/Off-net, antivirus software, vulnerability status, and others)

It also requests and obtains a client device certificate from the EMS ZTNA Certificate Authority (CA) when it registers to FortiClient EMS. The client uses this certificate to identify itself to the FortiGate.

FortiClient EMS

FortiClient EMS issues and signs the client certificate with the FortiClient UID, certificate serial number, and EMS serial number. The certificate is then synchronized to the FortiGate. EMS also shares its EMS ZTNA CA certificate with the FortiGate, so that the FortiGate can use it to authenticate the clients.

FortiClient EMS uses zero trust tagging rules to tag endpoints based on the information that it has on each endpoint. The tags are also shared with the FortiGate. See [Endpoint Posture Check Reference](#) for a list of the endpoint posture checks that EMS can perform.

Each ZTNA tag creates two firewall addresses in all VDOMs on a FortiGate. One firewall address is the IP address, and the other firewall address is the MAC address. Because each FortiGate model has a global limit and a per-VDOM limit for the maximum number of supported firewall addresses, the FortiGate model determines the maximum number of ZTNA tags allowable by that unit, which is the maximum number of firewall address divided by two. For each FortiGate model's limit, see the Maximum Values table.

FortiGate

The FortiGate maintains a continuous connection to the EMS server to synchronize endpoint device information, including primarily:

- FortiClient UID
- Client certificate SN
- EMS SN
- Device credentials (user/domain)
- Network details (IP and MAC address and routing to the FortiGate)

When a device's information changes, such as when a client moves from on-net to off-net, or their security posture changes, EMS is updated with the new device information and then updates the FortiGate. The FortiGate's WAD daemon can use this information when processing ZTNA traffic. If an endpoint's security posture change causes it to no longer match the ZTNA policy criteria on an existing session, then the session is terminated.

Certificate management on FortiClient EMS

FortiClient EMS has a *default_ZTNARootCA* certificate generated by default that the ZTNA CA uses to sign CSRs from the FortiClient endpoints. Clicking the refresh button revokes and updates the root CA, forcing updates to the FortiGate and FortiClient endpoints by generating new certificates for each client.

Do not confuse the EMS CA certificate (ZTNA) with the SSL certificate. The latter is the server certificate that is used by EMS for HTTPS access and fabric connectivity to the EMS server.

EMS can also manage individual client certificates. To revoke the current client certificate that is used by the endpoint: go to *Endpoint > All Endpoints*, select the client, and click *Action > Revoke Client Certificate*.

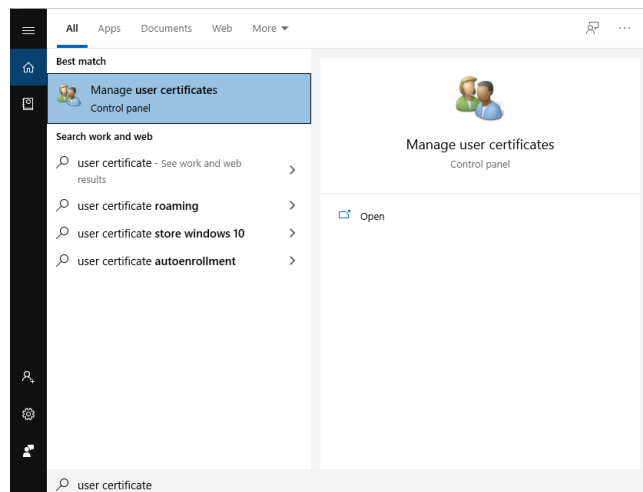

Locating and viewing the client certificate on an endpoint

In Windows, FortiClient automatically installs certificates into the certificate store. The certificate information in the store, such as certificate UID and SN, should match the information on EMS and the FortiGate.

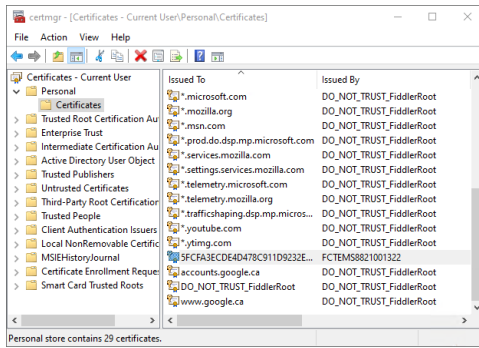

To locate certificates on other operating systems, consult the vendor documentation.

To locate the client certificate and EMS ZTNA CA certificate on a Windows PC:

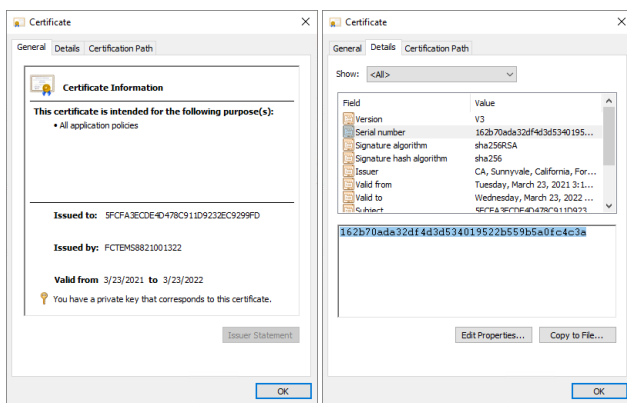

1. In the Windows search box, enter *user certificate* and click *Manage user certificates* from the results.

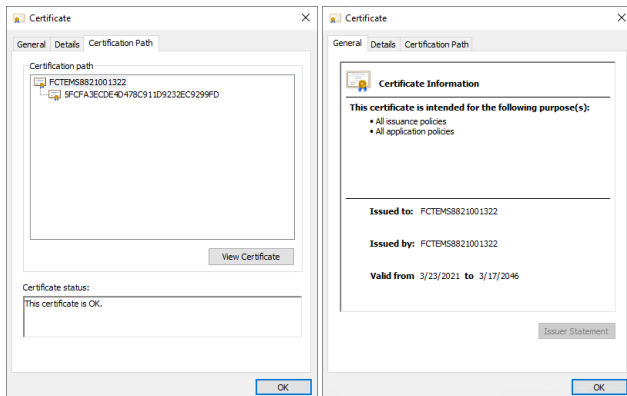

2. In the certificate manager, go to *Certificates - Current User > Personal > Certificates* and find the certificate that is issued by the FortiClient EMS.

3. Right-click on it and select Properties.
4. The **General** tab shows the client certificate UID and the issue and expiry dates. The **Details** tab show the certificate SN.

5. Go to the **Certificate Path** tab to see the full certificate chain.
6. Select the root CA and click **View Certificate** to view the details about the EMS ZTNA CA certificate.

Verifying that the client information is synchronized to the FortiGate

The following diagnose commands help to verify the presence of matching endpoint record, and information such as the client UID, client certificate SN, and EMS certificate SN on the FortiGate. If any of the information is missing or incomplete, client certificate authentication might fail because the corresponding endpoint entry is not found. More in-depth diagnosis would be needed to determine the reason for the missing records.

Command	Description
# diagnose endpoint record list <ip>	Show the endpoint record list. Optionally, filter by the endpoint IP address.
# diagnose wad dev query-by uid <uid> <ems sn> <ems tenant id>	Query from WAD diagnose command by UID.
# diagnose wad dev query-by ipv4 <ip>	Query from WAD diagnose command by IP address.
# diagnose test application fcnacd 7 # diagnose test application fcnacd 8	Check the FortiClient NAC daemon ZTNA and route cache.
#diagnose test application fcnacd 5	Force a sync with the FortiClient EMS server.

To check the endpoint record list for IP address 10.0.3.2:

```
# diagnose endpoint record list 10.0.3.2
Record #1:
    IP Address = 10.0.3.2
    MAC Address = 02:09:0f:00:03:03
    MAC list =
    VDOM = (-1)
    EMS serial number: FCTEMS8822001975
    EMS tenant id: 00000000000000000000000000000000
    Client cert SN: 2B8D4FF0E71FE7E064288FE1B4F87E25232092D0
    Public IP address: 34.23.223.220
    Quarantined: no
    Online status: online
    Registration status: registered
    On-net status: on-net
    Gateway Interface:

ZTNA scalability support for concurrent endpoints

ZTNA scalability supports up to 50 thousand concurrent endpoints. Communication between FortiOS and FortiClient EMS has efficient queries that request incremental updates. Retrieved device information can be written to the FortiClient NAC daemon cache.

FortiOS can receive tag information from the EMS common tags API. This feature requires FortiClient EMS 7.0.3 or later.

The APIs `api/v1/report/fct/uid_tags` and `api/v1/report/fct/tags` replace the API `api/v1/report/fct/host_tags`.

To use the common tags API capability:**1. Enable the common tags API when connecting the EMS:**

```
config endpoint-control fctems
    edit "local.ems"
        set server "10.6.30.213"
        set capabilities fabric-auth silent-approval websocket websocket-malware push-
ca-certs common-tags-api
    next
end
```

2. The FortiGate uses the new APIs to obtain device information from the EMS:

```
[ec_ems_context_submit_work:414] Call submitted successfully.
    obj-id: 11, desc: REST API to get updates of tag endpoints., entry:
api/v1/report/fct/tags.
[ec_ems_context_submit_work:414] Call submitted successfully.
    obj-id: 12, desc: REST API to get updates of tags associated with FCT UID., entry:
api/v1/report/fct/uid_tags.
[ec_ez_worker_process:334] Processing call for obj-id: 11, entry:
"api/v1/report/fct/tags"
[dynamic_addr_ha_act:215] called (EMS SN N/A).
[dynamic_addr_ha_act:215] called (EMS SN N/A).
[ec_ez_worker_process:441] Call completed successfully.
    obj-id: 11, desc: "REST API to get updates of tag endpoints.", entry:

[ec_ez_worker_process:334] Processing call for obj-id: 12, entry:
"api/v1/report/fct/uid_tags"
[ec_record_sync_tags_info_store:1419] Received 1 tags for
3D86DF70B85E16CBAD67908A897B4494 with sn FCTEMS8888888888
[ec_record_sync_tags_info_store:1419] Received 1 tags for
DA12930442F13F84D2441F03FCB6A10E with sn FCTEMS8888888888
[ec_record_sync_tags_info_store:1419] Received 1 tags for
25C59C275F257F4C5FBC7F6F5F56788E with sn FCTEMS8888888888
[ec_ez_worker_process:441] Call completed successfully.
    obj-id: 12, desc: "REST API to get updates of tags associated with FCT UID.", entry:
"api/v1/report/fct/uid_tags".
[ec_ems_context_submit_work:414] Call submitted successfully.
    obj-id: 7, desc: REST API to get updates about system info., entry:
api/v1/report/fct/sysinfo.
[ec_ems_context_submit_work:414] Call submitted successfully.
    obj-id: 11, desc: REST API to get updates of tag endpoints., entry:
api/v1/report/fct/tags.
[ec_ez_worker_process:334] Processing call for obj-id: 11, entry:
"api/v1/report/fct/tags"
[ec_ez_worker_process:441] Call completed successfully.
    obj-id: 11, desc: "REST API to get updates of tag endpoints.", entry:
"api/v1/report/fct/tags".
(.....)
```

3. Confirm that the device information from the EMS is written to the FortiClient NAC daemon cache:

```
# diagnose endpoint record list
...
    Avatar source: OS
    Phone number:
    Number of Routes: (1)
```

```

Gateway Route #0:
- IP:10.1.91.6, MAC: 4f:8d:c2:73:dd:fe, Indirect: no
- Interface:port2, VFID:1, SN: FG5H1E5999999999
online records: 37174; offline records: 0; quarantined records: 0; out-of-sync records:
0

```

4. Use the tags that are pulled from the EMS in a firewall address:

```

config firewall address
  edit "FCTEMS8888888888_ZT_AD_MGMT"
    set type dynamic
    set sub-type ems-tag
    set obj-tag "ZT_AD_MGMT"
    set tag-type "zero_trust"
  next
end

```

5. Check the tags' resolved IP and MAC addresses:

```

# diagnose firewall fqdn getinfo-ip FCTEMS8888888888_ZT_AD_MGMT
getinfo FCTEMS8888888888_ZT_AD_MGMT id:114 generation:106 count:187 data_len:6160 flag 0

# diagnose firewall fqdn getinfo-mac MAC_FCTEMS8888888888_ZT_AD_MGMT
getinfo MAC_FCTEMS8888888888_ZT_AD_MGMT id:163 generation:105 count:371 data_len:2226
flag 0

# diagnose firewall dynamic address FCTEMS8888888888_ZT_AD_MGMT

```

SSL certificate based authentication

A client certificate is obtained when an endpoint registers to EMS. FortiClient automatically submits a CSR request and the FortiClient EMS signs and returns the client certificate. This certificate is stored in the operating system's certificate store for subsequent connections. The endpoint information is synchronized between the FortiGate and FortiClient EMS. When an endpoint disconnects or is unregistered from EMS, its certificate is removed from the certificate store and revoked on EMS. The endpoint obtains a certificate again when it reconnected the EMS.

By default, client certificate authentication is enabled on the access proxy, so when the HTTPS request is received the FortiGate's WAD process challenges the client to identify itself with its certificate. The FortiGate makes a decision based on the following possibilities:

1. If the client responds with the correct certificate that the client UID and certificate SN can be extracted from:
 - If the client UID and certificate SN match the record on the FortiGate, the client is allowed to continue with the ZTNA proxy rule processing.
 - If the client UID and certificate SN do not match the record on the FortiGate, the client is blocked from further ZTNA proxy rule processing.
2. If the client cancels and responds with an empty client certificate:
 - If `empty-cert-action` is set to `accept`, the client is allowed to continue with ZTNA proxy rule processing.
 - If `empty-cert-action` is set to `block`, the client is blocked from further ZTNA proxy rule processing.

To configure the client certificate actions:

```
config firewall access-proxy
  edit <name>
    set client-cert {enable | disable}
    set empty-cert-action {accept | block | accept-unmanageable}
  next
end
```

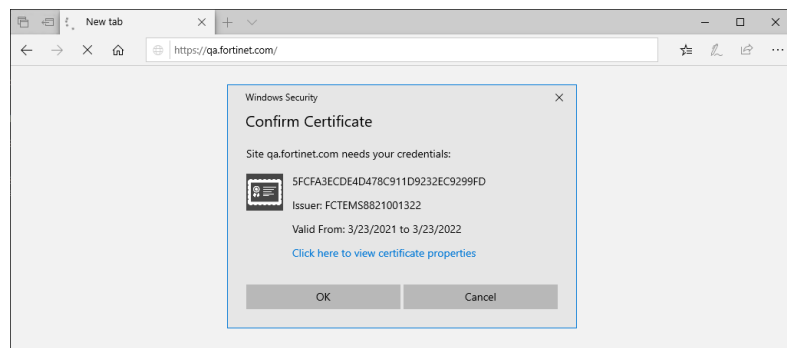

Example

In this example, a client connects to *qa.fortinet.com* and is prompted for a client certificate.

- `client-cert` is set to `enable`, and `empty-cert-action` is set to `block`.
- The ZTNA server is configured, and a ZTNA policy is set to allow this client.
- The domain resolves to the FortiGate access proxy VIP.

Scenario 1:

When prompted for the client certificate, the client clicks *OK* and provides a valid certificate that is verified by the FortiGate.

Result:

The client passes SSL certificate authentication and is allowed to access the website.

Scenario 2:

When prompted for the client certificate, the client clicks *Cancel*, resulting in an empty certificate response to the access proxy.

Result:

Because the certificate response is empty and `empty-cert-action` is set to `block`, the WAD daemon blocks the connection.

Currently, the Microsoft Edge, Google Chrome, and Safari browsers are supported by ZTNA.

Full versus simple ZTNA policies

There are two ways to configure ZTNA rules in the GUI by using a full or simple ZTNA policy.

Full ZTNA policy

In a full ZTNA policy, the CLI configuration remains the same as previous versions. In the GUI, the *Policy & Objects > ZTNA > ZTNA Rules* tab has been removed. Administrators can configure ZTNA policies from the *Policy & Objects > Proxy Policy* page, and by setting the *Type* to *ZTNA*.

Simple ZTNA policy

In a simple ZTNA policy, a regular firewall policy is used for policy management. When creating a new firewall policy, administrators can configure a ZTNA policy by setting the *Type* to *ZTNA*.

Hot Questions at FortiAnswers

[Is Web Cache on the GUI?](#)

1 Answers 0 Votes 252 Views

[See More](#)

A simple ZTNA policy cannot control access based on the destination interface or the real server's destination address. See the [Examples](#) section for detailed configurations.

Authentication for ZTNA policies

Authentication remains largely the same between both ZTNA policy configuration modes. You can specify user groups under *Source* to define the groups in which the access control applies to. However, the underlying authentication schemes and rules must still be in place to direct the traffic to the ZTNA application gateway.

Authentication for regular firewall policies

Authentication for regular firewall policies is traditionally handled by authd, which does not require an authentication scheme and rules to be configured in order to function. This enhancement allows authentication for regular firewall policies to be handled by WAD so that the authentication scheme and rules are used to determine the type of

authentication and the traffic that requires authentication. This option is disabled by default, but can be enabled as follows:

```
config firewall auth-portal
    set proxy-auth {enable | disable}
end
```

Redirecting a simple ZTNA policy to a full ZTNA policy

An option is added so that after matching a simple ZTNA policy, the traffic can be redirected for a full ZTNA policy match. This setting can only be configured from the CLI, and it is disabled by default.

```
config firewall policy
    edit <id>
        set ztna-policy-redirect {enable | disable}
    next
end
```

For example, a client has both tag A and tag B. In the simple ZTNA policy, the client matches a policy that requires tag A for a posture check. If they are using the `ztna-policy-redirect` option, then it will also require a full ZTNA policy match.

If a full ZTNA policy allows either tag A or tag B or all traffic in general, then the traffic is allowed. Otherwise, if a full ZTNA policy explicitly denies one of the tags, the traffic will be denied.

If no full ZTNA policy is matched, then the traffic is implicitly denied.

Examples

The following examples demonstrate how to configure a ZTNA policy using the full and simple ZTNA policy modes.

It is assumed that the following settings are already configured:

- EMS connection and EMS tags (Malicious-File-Detected and FortiAD.Info)
- ZTNA server configuration (ZTNA-webserver)
- Authentication scheme and rule

Configuring a full ZTNA policy

To configure a full ZTNA policy in the GUI:

1. Go to *Policy & Objects > Proxy Policy* and click *Create New*.
2. Configure the following settings:

Name	<i>ZTNA-webserver</i>
Type	<i>ZTNA</i>
Incoming Interface	<i>port3</i>
Source	<i>all</i>
Destination	<i>Webserver1 (10.88.0.3/32)</i>
ZTNA Server	<i>ZTNA-webserver</i>
Schedule	<i>always</i>
Action	<i>ACCEPT</i>

3. Click **OK**.

To configure a full ZTNA policy in the CLI:

```
config firewall proxy-policy
  edit 1
    set name "ZTNA-webserver"
    set proxy access-proxy
    set access-proxy "ZTNA-webserver"
    set srcintf "port3"
    set srcaddr "all"
    set dstaddr "Webserver1"
    set action accept
    set schedule "always"
  next
end
```

When traffic is allowed, the ZTNA logs show traffic passing through policy 1 on a policy called *ZTNA-webserver*, which is a proxy policy.

To verify the traffic logs:

```
# execute log filter category traffic
# execute log filter field subtype ztna
# execute log display
9 logs found.
9 logs returned.
1: date=2023-03-06 time=20:16:11 eventtime=1678162572109525759 tz="-0800" logid="0005000024"
type="traffic" subtype="ztna" level="notice" vd="root" srcip=10.0.3.2 srcport=28597
srcintf="port3" srcintfrole="wan" dstcountry="Reserved" srccountry="Reserved"
dstip=10.88.0.3 dstport=9443 dstintf="port2" dstintfrole="dmz" sessionid=20140
srcuuid="b458a65a-f759-51ea-d7df-ef2e750026d1" service="tcp/9443" proxyapptype="http"
proto=6 action="accept" policyid=1 policytype="proxy-policy" poluuid="1c0a04b8-bc85-51ed-
48ba-7d43279fb899" policyname="ZTNA-webserver" duration=3604 gatewayid=1 vip="ZTNA-
webserver" accessproxy="ZTNA-webserver" clientdevicemanageable="manageable" wanin=303150
rcvdbyte=303150 wanout=3755 lanin=2813 sentbyte=2813 lanout=304697 appcat="unscanned"
```

Configuring a simple ZTNA policy

To configure a simple ZTNA policy in the GUI:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	<i>ZTNA-webserver-fp</i>
Type	<i>ZTNA</i>
Incoming Interface	<i>port3</i>
Source	<i>all</i>
Destination	<i>ZTNA-webserver</i>
Schedule	<i>always</i>
Action	<i>ACCEPT</i>

3. Click *OK*.

To configure a simple ZTNA policy in the CLI:

```
config firewall policy
  edit 9
    set name "ZTNA-webserver-fp"
    set srcintf "port3"
    set dstintf "any"
    set action accept
    set srcaddr "all"
    set dstaddr "ZTNA-webserver"
    set schedule "always"
    set service "ALL"
  next
end
```

When traffic is allowed, the ZTNA logs show traffic passing through policy 9 on a policy called *ZTNA-webserver-fp*, which is a firewall policy.

To verify the traffic logs:

```
# execute log filter category traffic
# execute log filter field subtype ztna
# execute log display
14 logs found.
10 logs returned.
```

```
1: date=2023-03-06 time=23:01:55 eventtime=1678172515724776640 tz="-0800" logid="0005000024"
type="traffic" subtype="ztna" level="notice" vd="root" srcip=10.0.3.2 srcport=31687
srcintf="port3" srcintfrole="wan" dstcountry="Reserved" srccountry="Reserved"
dstip=10.88.0.3 dstport=9443 dstintf="port2" dstintfrole="dmz" sessionid=28076

rcvdbyte=3445 wanout=1189 lanin=2358 sentbyte=2358 lanout=4759 appcat="unscanned"
```

Configuring a ZTNA simple policy with ZTNA tags and authentication

In this example, a simple ZTNA policy uses the FortiAD.Info tag for a posture check and authentication against a pre-configured Active Directory server where the user tsmith resides. The authentication scheme and rule have already been configured as follows:

```
config authentication scheme
    edit "ZTNA-Auth-scheme"
        set method basic
        set user-database "LDAP-fortiad"
    next
end

config authentication rule
    edit "ZTNA-Auth-rule"
        set srcintf "port3"
        set srcaddr "all"
        set active-auth-method "ZTNA-Auth-scheme"
    next
end
```

To append ZTNA tag and authentication settings to the simple ZTNA policy:

1. Go to *Policy & Objects > Firewall Policy* and edit the *ZTNA-webserver-fp* policy.
2. For the *Source* field, click the + and add the user group named *LDAP-Remote-Allowed-Group*.
3. For the *ZTNA Tag* field, click the + and add the *FortiAD.Info* tag.
4. Click *OK*.

To verify the configuration:

1. Connect to the web server from a client.
2. After selecting the client certificate, the browser will prompt for a username and password. Enter the username (tsmith) and their password.

Upon a successful authentication, the user will be able to access the web server.

3. On the FortiGate, verify that the logs for the allowed traffic show the user tsmith and the tag EMS1_ZTNA_FortiAD.Info:

```
# execute log filter field subtype ztna
# execute log display
18 logs found.
10 logs returned.
1: date=2023-03-06 time=23:25:23 eventtime=1678173923745891128 tz="-0800"
logid="0005000024" type="traffic" subtype="ztna" level="notice" vd="root" srcip=10.0.3.2
srcport=32017 srcintf="port3" srcintfrole="wan" dstcountry="Reserved"
srccountry="Reserved" dstip=10.88.0.3 dstport=9443 dstintf="port2" dstintfrole="dmz"
sessionid=29615 srcuuid="b458a65a-f759-51ea-d7df-ef2e750026d1" service="tcp/9443"
proxyapptype="http" proto=6 action="accept" policyid=9 policytype="proxy-policy"
poluid="1f1d5036-bcaa-51ed-1d28-687edafe9439" policyname="ZTNA-webserver-fp"
duration=106 user="tsmith" group="LDAP-Remote-Allowed-Group" authserver="LDAP-fortiad"
gatewayid=1 vip="ZTNA-webserver" accessproxy="ZTNA-webserver"
```

```
clientdeviceid="9A016B5A6E914B42AD4168C066EB04CA" clientdevicemanageable="manageable"
clientdevicetags="MAC_EMS1_ZTNA_all_registered_clients/EMS1_ZTNA_all_registered_
clients/MAC_EMS1_ZTNA_FortiAD.Info/EMS1_ZTNA_FortiAD.Info" emsconnection="online"
wanin=301793 rcvdbyte=301793 wanout=3331 lanin=2877 sentbyte=2877 lanout=333000

```

ZTNA advanced configurations

This section includes the following ZTNA advanced configurations:

- [Access control of unmanageable and unknown devices on page 1087](#)
- [HTTP2 connection coalescing and concurrent multiplexing for ZTNA on page 1094](#)
- [Mapping ZTNA virtual host and TCP forwarding domains to the DNS database on page 1096](#)

Access control of unmanageable and unknown devices

The ZTNA application gateway can determine whether a client device that does not have FortiClient installed is a mobile device that is considered unmanageable, or is not a mobile device that is considered unknown. The ZTNA application gateway tags the device as either `EMS_ALL_UNMANAGEABLE_CLIENTS` or `EMS_ALL_UNKNOWN_CLIENTS` respectively. The FortiGate WAD process achieves this by either matching device TLS fingerprints against a library or learning information from the HTTP User-Agent header if the `set user-agent-detect` setting is enabled.

Configuring the ZTNA access proxy and proxy policy

The `EMS_ALL_UNMANAGEABLE_CLIENTS` and `EMS_ALL_UNKNOWN_CLIENTS` tags allow for ZTNA access control of unmanageable and unknown devices using a proxy policy. The `accept-unmanageable` option for the `empty-cert-action` setting allows unmanageable clients to continue ZTNA proxy rule processing.

```
config firewall access-proxy
    edit <name>
        set client-cert enable
        set user-agent-detect {enable | disable}
        set empty-cert-action {accept | block | accept-unmanageable}
    next
end
```

<code>user-agent-detect {enable disable}</code>	Enable/disable detecting the device type by HTTP User-Agent if no client certificate is provided (default = enable).
<code>empty-cert-action {accept block accept-unmanageable}</code>	Set the action for an empty client certificate: <ul style="list-style-type: none"> • <code>accept</code>: accept the SSL handshake if the client certificate is empty. • <code>block</code>: block the SSL handshake if the client certificate is empty. • <code>accept-unmanageable</code>: accept the SSL handshake only if the end point is unmanageable.

The `user-agent-detect` and `empty-cert-action` settings can only be configured in the CLI.

```
config firewall proxy-policy
    edit <id>
```

```

        set ztna-ems-tag {EMS_ALL_UNMANAGEABLE_CLIENTS | EMS_ALL_UNKNOWN_CLIENTS}
    next
end

```

```

ztna-ems-tag {EMS_ALL_
  UNMANAGEABLE_CLIENTS
  | EMS_ALL_UNKNOWN_
  CLIENTS}

```

Set the EMS tag names:

- EMS_ALL_UNMANAGEABLE_CLIENTS: match any device that is unmanageable.
- EMS_ALL_UNKNOWN_CLIENTS: match any device that is not recognized.

Consider the following use cases.

- Case 1: if a client device sends a TLS client hello in a mobile pattern, then WAD will try to match its TLS fingerprint with a WAD original library and mark it with an EMS_ALL_UNMANAGEABLE_CLIENTS tag.
- Case 2: if WAD cannot match the TLS fingerprint with an original library but user-agent-detect is enabled (under config firewall access-proxy), WAD will try to learn the device type from client request's User-Agent header. If it matches a mobile device, then it is still marked with an EMS_ALL_UNMANAGEABLE_CLIENTS tag.
- Case 3: if WAD cannot match the TLS fingerprint with an existing original or temporary library, or cannot learn it from User-Agent header, or user-agent-detect is disabled, then it will mark the device as EMS_ALL_UNKNOWN_CLIENTS.

In the access proxy settings, if empty-cert-action is set to accept-unmanageable, then only case 1 and 2 would go through the proxy policy. Case 3 would be denied, and a replacement message page would appear.

To configure ZTNA policy access control of unmanageable devices:

1. Configure the client certificate actions:

```

config firewall access-proxy
    edit "zt1"
        set vip "zt1"
        set client-cert enable
        set user-agent-detect enable
        set auth-portal disable
        set empty-cert-action accept
        set log-blocked-traffic disable
        set add-vhost-domain-to-dnsdb disable
        set decrypted-traffic-mirror ''
    next
end

```

2. Configure the proxy policy with the ZTNA EMS tag to control device access:

```

config firewall proxy-policy
    edit 1
        set proxy access-proxy
        set access-proxy "zt1"
        set srcintf "port2" "ag2"
        set srcaddr "all"
        set dstaddr "all"
        set ztna-ems-tag "EMS_ALL_UNMANAGEABLE_CLIENTS"
    next
end

```

Configuring dynamic address local tags

Like other ZTNA tags, `EMS_ALL_UNMANAGEABLE_CLIENTS` and `EMS_ALL_UNKNOWN_CLIENTS` are dynamic addresses on the FortiGate. The following diagnostic commands can be used to view local tag information:

- `diagnose firewall dynamic address`: a list of unmanageable and unknown clients' IP addresses associated with the `EMS_ALL_MANAGEABLE_CLIENTS` and `EMS_ALL_UNKNOWN_CLIENTS` dynamic addresses, respectively, is displayed.
- `diagnose user-device-store device memory list`: when device detection is enabled on a FortiGate interface that has a layer 2 connection to unmanageable and unknown device clients, then a client's device information is displayed.

To verify the list of dynamic firewall addresses in the CLI:

```
(vdom1) # diagnose firewall dynamic address
List all dynamic addresses:
IP dynamic addresses in VDOM vdom1(vfid: 1):
...
CMDB name: EMS_ALL_UNMANAGEABLE_CLIENTS
EMS_ALL_UNMANAGEABLE_CLIENTS: ID(101)
    ADDR(10.1.100.22)
Total IP dynamic range blocks: 1.
Total IP dynamic addresses: 1.
CMDB name: EMS_ALL_UNKNOWN_CLIENTS
EMS_ALL_UNKNOWN_CLIENTS: ID(154)
Total IP dynamic range blocks: 0.
Total IP dynamic addresses: 0.
...
```

To verify the client device information in the CLI:

```
(vdom1) # diagnose user-device-store device memory list
Record #1:
...
device_info
...
    'is_online' = 'true'
    'is_ems_registered' = 'false'
    'active_start_time' = '1668811449'
    'is_fortiguard_src' = 'false'
    'tags' = 'EMS_ALL_UNMANAGEABLE_CLIENTS'
...
interface_info
...
```

To view the local tag information in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Tags* tab.

Viewing ZTNA traffic logs

ZTNA traffic logs include the following fields related to unmanageable and unknown devices.

- Client connection status with EMS server with possible values of unknown, offline, or online:
 - CLI = `emsconnection`
 - GUI = *EMS Connection*
- Device manageability status with possible values of unknown, manageable, or unmanageable:
 - CLI = `clientdevicemanageable`
 - GUI = *Client Device Manageable*

The device manageability status can have one of the following values:

- Unknown: traffic from a client with an unknown TLS fingerprint and where the user agent information is not available for learning.
- Manageable: traffic from a non-mobile device (platform or operating system), with a known TLS fingerprint, or where the user agent information is available for learning.
- Unmanageable: traffic from a mobile device with a known mobile TLS fingerprint or user agent information is available for learning.

To view the ZTNA traffic logs in the CLI:

```
(vdom1)# execute log filter category 0
(vdom1)# execute log filter field subtype ztna
(vdom1)# execute log display
```

```
1: date=2022-11-18 time=14:23:57 eventtime=1668810238188622828 tz="-0800" logid="0005000024"

To view the ZTNA traffic logs in the GUI:

1. Go to *Log & Report > ZTNA Traffic*.
2. Select an entry and click *Details*.
3. Check the *Client Device Manageable* and *EMS Connection* fields.

#	Date/Time	ZTNA Server	Service	Result	Policy ID	Client Device Manageable	EMS Connection	Action	Log Details

HTTP2 connection coalescing and concurrent multiplexing for ZTNA

HTTP2 connection coalescing and concurrent multiplexing allows multiple HTTP2 requests to share the same TLS connection when the destination IP is the same, and the host names are compatible in the certificate. In ZTNA scenarios, the FortiGate application gateway may accept multiple HTTP2 requests to the same ZTNA server destined to different virtual hosts on the same real server. These HTTP2 requests can share the same TLS connection between the FortiGate and the real server so that the handshake does not need to be performed multiple times for multiple connections.

In order for the FortiGate to match the SNI (Server Name Indication), this SNI value must appear under the SAN extension on the server certificate. Configuring the SNI value under the CN alone will not work.

To configure the ZTNA access proxy:

```
config firewall access-proxy
  edit <name>
    set http-supported-max-version {http1 | http2}
    set svr-pool-multiplex {enable | disable}
    set svr-pool-ttl <integer>
    set svr-pool-server-max-request <integer>
  next
end
```

http-supported-max-version {http1 http2}	Set the maximum supported HTTP version: <ul style="list-style-type: none"> http1: support HTTP 1.1 and HTTP1. http2: support HTTP2, HTTP 1.1, and HTTP1 (default).
svr-pool-multiplex {enable disable}	Enable/disable server pool multiplexing. When enabled, share the connected server in HTTP, HTTPS, and web portal API gateway.
svr-pool-ttl <integer>	Set the time-to-live in the server pool for idle connections to servers (in seconds, 0 - 2147483647, default = 15).
svr-pool-server-max-request <integer>	Set the maximum number of requests that servers in server pool handle before disconnecting (0 - 2147483647, default = 0).

Example

In this example, multiple clients submit requests in HTTP2. The requests hit the VIP address, and then FortiGate opens a session between itself (172.16.200.6) and the server (172.16.200.99). The coalescing occurs in this session as the multiple streams share the same TLS session to connect to the same destination server.

To configure connection coalescing and concurrent multiplexing with ZTNA:**1. Configure the VIP:**

```
config firewall vip
    edit "vip-ztna"
        set type access-proxy
        set extip 10.1.100.223
        set extintf "port2"
        set server-type https
        set extport 443
        set ssl-certificate "Fortinet_SSL"
    next
end
```

2. Configure the ZTNA server and path mapping:

```
config firewall access-proxy
    edit "ztna"
        set vip "vip-ztna"
        set client-cert disable
        set svr-pool-multiplex enable
        set http-supported-max-version http2
        config api-gateway
            edit 1
                set url-map "/a"
                set virtual-host "a.ftnt.com"
                config realservers
                    edit 1
                        set ip 172.16.200.99
                    next
                end
            next
            edit 2
                set url-map "/b"
                set virtual-host "b.ftnt.com"
                config realservers
                    edit 1
                        set ip 172.16.200.99
                    next
                end
            next
        end
    next
end
next
end
```

3. Configure the ZTNA policy:

```
config firewall proxy-policy
    edit 3
        set proxy access-proxy
        set access-proxy "ztna"
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set logtraffic all
```

```

set utm-status enable
set ssl-ssh-profile "deep-inspection-clone"
set av-profile "av"
next
end

```

- Get the clients to access a.ftnt.com and b.ftnt.com. The clients share access with the same real server and certificate (CN=*.ftnt.com). The FortiGate shares the first TLS connection with second TLS connection.
- Verify the sniffer packet capture on the FortiGate server side. There is one client hello.

17	0.022590	172.16.200.6	172.16.200.99	TLSv1.2	145	Application Data
18	0.022686	172.16.200.99	172.16.200.6	TCP	66	443 → 6888 [ACK] Seq=2316 Ack=663 Win=64640 Len=0 TSval=834657471 TSecr=806057
19	0.022935	172.16.200.99	172.16.200.6	TLSv1.2	122	Application Data
20	0.022987	172.16.200.6	172.16.200.99	TLSv1.2	268	Application Data
21	0.022993	172.16.200.6	172.16.200.99	TCP	66	6888 → 443 [ACK] Seq=663 Ack=2566 Win=176128 Len=0 TSval=806057 TSecr=834657471
22	0.023285	172.16.200.6	172.16.200.99	TLSv1.2	108	Application Data
23	0.065172	172.16.200.99	172.16.200.6	TCP	66	443 → 6888 [ACK] Seq=2566 Ack=705 Win=64640 Len=0 TSval=834657513 TSecr=806057

- Disable server pool multiplexing:

```

config firewall access-proxy
edit "zttna"
set vip "vip-ztna"
set svr-pool-multiplex disable
next
end

```

- Verify the sniffer packet capture. This time, the FortiGate does not coalesce the TLS connection, so there are two client hellos.

No.	Time	Source	Destination	Protocol	Length	Info

Mapping ZTNA virtual host and TCP forwarding domains to the DNS database

When ZTNA application gateway is deployed on a FortiGate in the network, remote clients need to be able to reach the protected resources via their host addresses that resolves to the ZTNA application gateway's virtual IP. One way of registering these addresses is through the DNS server on the FortiGate.

While it is possible to manually manage the list of hosts and their mapped external VIP addresses on the FortiGate's DNS database or on an external DNS, there may be some drawbacks. One drawback is you may not want to expose the internal host names and addresses publicly. Secondly, you may not want to manually maintain the list of host addresses and mappings.

As such, there is a setting to automatically map a virtual host or TCP forwarding domain directly to the external VIP address of the ZTNA access proxy.

```

config firewall access-proxy
edit <name>

```

```

    set add-vhost-domain-to-dnsdb {enable | disable}
  next
end

```

```

add-vhost-domain-to-dnsdb
{enable | disable}

```

When enabled, all virtual hosts and TCP forwarding domains in the access proxy will be added under `config system dns-database`.

The mapping of one virtual host is restricted to one access proxy entry only. The same virtual host cannot be used in multiple access proxy entries.

Once enabled, the virtual host or TCP forwarding domain will be added to a `shadow-ztna` type DNS database. This type of DNS is hidden in the GUI and CLI, but is published through API to connecting ZTNA clients over a DoH/DoT tunnel. The FortiClient endpoint learns about these virtual host addresses and is able to redirect those traffic to the appropriate ZTNA access proxy.

The `shadow-ztna` option is a hidden setting under `dns-database`:

```

config system dns-database
  edit <name>
    set view {shadow | public | shadow-ztna}
  next
end

```

```

view {shadow | public |
shadow-ztna}

```

Set the zone view:

- `shadow`: shadow DNS zone to serve internal clients.
- `public`: public DNS zone to serve public clients.
- `shadow-ztna` (hidden): resolve to the ZTNA VIP. This implicit DNS zone is only visible to clients connecting to the ZTNA DoT/DoH tunnel.

Example

In this example, the FortiGate has several ZTNA access proxies configured with different VIPs attached to each one.

Different virtual hosts and TCP forwarding domains are configured on each access proxy:

Access proxy	VIP address	Virtual host	TCP forwarding domain
ztna	172.18.82.66	vh1: test1.test.com vh2: test2.test.com	
ztna_2	172.18.82.67	vh3: test3.test.com	

Access proxy	VIP address	Virtual host	TCP forwarding domain
ztna_3	172.18.82.68		test4.test.com

Consequently, DNS entries with shadow ZTNA view are added to the local DNS database.

From the FortiClient endpoint, users will be able to access the protected resources using these addresses and mapping:

- address -> access proxy address -> real server address
- https://test1.test.com -> https://172.18.82.66 -> https://172.16.200.207
- https://test2.test.com -> https://172.18.82.66 -> https://172.16.200.123
- https://test3.test.com -> https://172.18.82.67 -> https://172.16.200.207
- TCP app test4.test.com -> 172.18.82.68:443 -> TCP app server

To configure the FortiGate:

1. Configure three access proxy VIPs:

```
config firewall vip
    edit "ztna"
        set type access-proxy
        set extip 172.18.82.66
        set extintf "any"
        set server-type https
        set extport 443
        set ssl-certificate "Fortinet_SSL"
    next
    edit "ztna_2"
        set type access-proxy
        set extip 172.18.82.67
        set extintf "any"
        set server-type https
        set extport 443
        set ssl-certificate "Fortinet_SSL"
    next
    edit "ztna_3"
        set type access-proxy
        set extip 172.18.82.68
        set extintf "any"
        set server-type https
        set extport 443
        set ssl-certificate "Fortinet_SSL"
    next
end
```

2. Configure three virtual hosts to be used in the ZTNA access proxies:

```
config firewall access-proxy-virtual-host
    edit "vh1"
        set ssl-certificate "*.test.com"
        set host "test1.test.com"
    next
    edit "vh2"
        set ssl-certificate "*.test.com"
        set host "test2.test.com"
    next
end
```

```

    edit "vh3"
        set ssl-certificate "*.test.com"
        set host "test3.test.com"
    next
end

```

3. Configure the first access proxy, and map virtual hosts vh1 and vh2 to different services:

```

config firewall access-proxy
    edit "ztna"
        set vip "ztna"
        set add-vhost-domain-to-dnsdb enable
        config api-gateway
            edit 1
                set virtual-host "vh1"
                config realservers
                    edit 1
                        set addr-type fqdn
                        set address "fqdn4"
                    next
                    edit 2
                        set ip 172.16.200.207
                    next
                end
            next
        edit 2
            set service http
            set virtual-host "vh2"
            config realservers
                edit 1
                    set ip 172.16.200.123
                next
            end
        next
    end
next
end

```

4. Configure the second access proxy, and map one service to virtual host vh3.

```

config firewall access-proxy
    edit "ztna_2"
        set vip "ztna_2"
        set add-vhost-domain-to-dnsdb enable
        config api-gateway
            edit 1
                set virtual-host "vh3"
                config realservers
                    edit 1
                        set ip 172.16.200.207
                    next
                end
            next
        end
    next
end

```

Since `add-vhost-domain-to-dnsdb` is enabled, a virtual host used in the other access proxy cannot be mapped to this access proxy.

5. Configure the third access proxy for TCP forwarding:

```
config firewall access-proxy
    edit "ztna_3"
        set vip "ztna_3"
        set add-vhost-domain-to-dnsdb enable
    config api-gateway
        edit 2
            set url-map "/tcp"
            set service tcp-forwarding
            config realservers
                edit 1
                    set domain "test4.test.com"
                next
            end
        next
    end
next
end
next
end
```

6. The virtual host and TCP forwarding domains are mapped to their corresponding access proxy VIP under the local DNS database. Each will appear as a shadow ZTNA entry.

These settings cannot be configured or edited in the GUI or CLI.

```
show full-configuration system dns-database
config system dns-database
    edit "test1.test.com"
        set domain "test1.test.com"
        set view shadow-ztna
        config dns-entry
            edit 1
                set ttl 86400
                set hostname "test1.test.com"
                set ip 172.18.82.66
            next
        end
        set primary-name "test1.test.com"
        set contact "fgt-ztna"
    next
    edit "test2.test.com"
        set domain "test2.test.com"
        set view shadow-ztna
        config dns-entry
            edit 1
                set ttl 86400
                set hostname "test2.test.com"
                set ip 172.18.82.66
            next
        end
        set primary-name "test2.test.com"
```

```
        set contact "fgt-ztna"
    next
    edit "test3.test.com"
        set domain "test3.test.com"
        set view shadow-ztna
        config dns-entry
            edit 1
                set ttl 86400
                set hostname "test3.test.com"
                set ip 172.18.82.67
            next
        end
        set primary-name "test3.test.com"
        set contact "fgt-ztna"
    next
    edit "test4.test.com"
        set domain "test4.test.com"
        set view shadow-ztna
        config dns-entry
            edit 1
                set ttl 86400
                set hostname "test4.test.com"
                set ip 172.18.82.68
            next
        end
        set primary-name "test4.test.com"
        set contact "fgt-ztna"
    next
end
```

7. Once a FortiClient endpoint registers to EMS and is able to retrieve the list of hosts from the FortiGate ZTNA service portal, it will be able to reach each of the hosts test1, test2, test3, and test4.test.com.

ZTNA configuration examples

This section includes the following ZTNA configuration examples:

- [ZTNA HTTPS access proxy example on page 1102](#)
- [ZTNA HTTPS access proxy with basic authentication example on page 1112](#)
- [ZTNA TCP forwarding access proxy example on page 1119](#)
- [ZTNA SSH access proxy example on page 1125](#)
- [ZTNA application gateway with SAML authentication example on page 1132](#)
- [ZTNA application gateway with SAML and MFA using FortiAuthenticator example on page 1136](#)
- [ZTNA IP MAC based access control example on page 1152](#)
- [ZTNA IPv6 examples on page 1159](#)
- [ZTNA Zero Trust application gateway example on page 1165](#)

ZTNA HTTPS access proxy example

In this example, an HTTPS access proxy is configured to demonstrate its function as a reverse proxy on behalf of the web server it is protecting. It verifies user identity, device identity, and trust context, before granting access to the protected source.

This example shows access control that allows or denies traffic based on ZTNA tags. Traffic is allowed when the FortiClient endpoint is tagged as *Low Importance* using Classification tags, and denied when the endpoint is tagged with *Malicious-File-Detected*.

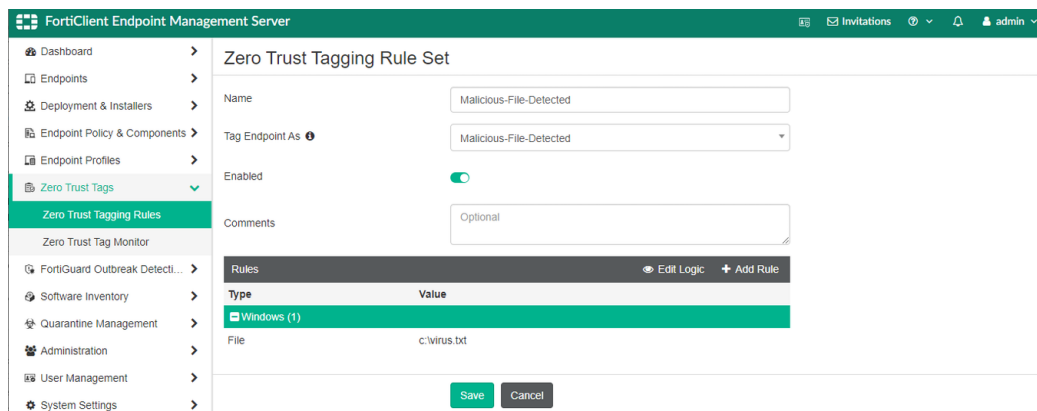

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

To configure ZTNA in the GUI, go to *System > Feature Visibility* and enable *Zero Trust Network Access*.

To configure a Zero Trust tagging rule on the FortiClient EMS:

1. Log in to the FortiClient EMS.
2. Go to *Zero Trust Tags > Zero Trust Tagging Rules*, and click *Add*.
3. In the *Name* field, enter *Malicious-File-Detected*.
4. In the *Tag Endpoint As* dropdown list, select *Malicious-File-Detected*.
EMS uses this tag to dynamically group together endpoints that satisfy the rule, as well as any other rules that are configured to use this tag.
5. Click *Add Rule* then configure the rule:
 - a. For OS, select *Windows*.
 - b. From the *Rule Type* dropdown list, select *File* and click the + button.
 - c. Enter a file name, such as *C:\virus.txt*.
 - d. Click *Save*.

6. Click **Save**.

To configure FortiClient EMS to share classification tags:

1. Go to *Administration > Fabric Devices*.
2. Select the FortiGate device.
3. Click *Edit*.
4. Under *Tag Types Being Shared*, add *Classification Tags*.

5. Click **Save**.

To configure a ZTNA server for HTTPS access proxy in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Set *Name* to *ZTNA-webserver*.
4. Configure the network settings:
 - a. Set *External interface* to *port3*.
 - b. Set *External IP* to *10.0.3.10*.
 - c. Set *External port* to *9443*.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.
6. Add server mapping:

- a. In the *Service/server mapping* table, click *Create New*.
- b. Set *Service* to *HTTPS*.
- c. Set *Virtual Host* to *Any Host*.
- d. Configure the path as needed. For example, to map to *webserver.ztnademo.com/fortigate*, enter */fortigate*.
- e. Add a server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Set *IP* to *10.88.0.3*.
 - iii. Set *Port* to *9443*.
 - iv. Click *OK*.

New Service/Server Mapping

Type: IPv4

Service: HTTP HTTPS TCP Forwarding

Virtual Host: Any Host Specify

Match path by: Substring Wildcard Regular Expression

Path: /

Servers

Load balancing: ☐

Address	Port	Status
10.88.0.3	9443	Active

OK Cancel

- f. Click *OK*.

New ZTNA Server

Type: IPv4

Name: ZTNA-webserver

Comments:

Network

External Interface: WAN (port3)

External IP: 10.0.3.10

External port: 9443

SAML: ☐

Services and Servers

Default certificate: ztna-wildcard

Service/server mapping

Service	URL	# Real Servers
HTTPS	/	1

OK Cancel

7. Click *OK*.

To configure simple ZTNA policies to allow and deny traffic based on ZTNA tags in the GUI:

1. Go to *Policy & Objects > Firewall Policy*.
2. Create a rule to deny traffic:

- a. Click *Create New*.
- b. Set *Name* to *ZTNA-Deny-malicious*.
- c. Set *Type* to *ZTNA*.
- d. Set *Incoming Interface* to *port3*.
- e. Set *Source* to *all*.
- f. Add the ZTNA tag *Malicious-File-Detected*.
This tag is dynamically retrieved from EMS when you first created the Zero Trust Tagging Rule.
- g. Select the ZTNA server *ZTNA-webserver*.
- h. Set *Action* to *DENY*.
- i. Enable *Log Violation Traffic*.

The screenshot shows the 'Create New Policy' window in FortiGate. The configuration is as follows:

- Name:** ZTNA-Deny-Malicious
- Type:** Standard ZTNA
- Incoming Interface:** WAN (port3)
- Source:** all
- ZTNA Tag:** ZTNA Malicious-File-Detected
- ZTNA Server:** ZTNA-webserver
- Schedule:** always
- Action:** DENY (selected over ACCEPT)
- Log Violation Traffic:** Enabled (checkbox checked)
- Comments:** Write a comment... (0/1023)
- Enable this policy:** Enabled (checkbox checked)

The 'OK' button is highlighted in green, and the 'Cancel' button is in white.

- j. Click *OK*.
3. Create a rule to allow traffic:
 - a. Click *Create New*.
 - b. Set *Name* to *ZTNA-Allow-Simple*.
 - c. Set *Type* to *ZTNA*.
 - d. Set *Incoming Interface* to *port3*.
 - e. Set *Source* to *all*. This can also be set to specific IP addresses to only allow those addresses to connect to this HTTPS access proxy.
 - f. Add the *Class* tag *Low*.
 - g. Select the ZTNA server *ZTNA-webserver*.
 - h. Configure the remaining options as needed.
 - i. Click *OK*.
 4. On the firewall policy list, make sure that the deny rule (*ZTNA-Deny-malicious*) is above the allow rule (*ZTNA-Allow-Simple*).

To configure HTTPS access in the CLI:**1. Configure the access proxy VIP:**

```
config firewall vip
    edit "ZTNA-webserver"
        set type access-proxy
        set extip 10.0.3.10
        set extintf "port3"
        set server-type https
        set extport 9443
        set ssl-certificate "ztna-wildcard"
    next
end
```

2. Configure the server and path mapping:

```
config firewall access-proxy
    edit "ZTNA-webserver"
        set vip "ZTNA-webserver"
        set client-cert enable
        set log-blocked-traffic enable
        config api-gateway
            edit 1
                config realservers
                    edit 1
                        set ip 10.88.0.3
                        set port 9443
                    next
                end
            next
        end
    next
end
```

3. Configure ZTNA policies:

```
config firewall policy
    edit 9
        set name "ZTNA-Deny-Malicious"
        set srcintf "port3"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "ZTNA-webserver"
        set ztna-ems-tag "EMS1_ZTNA_Malicious-File-Detected"
        set schedule "always"
        set logtraffic all
    next
    edit 10
        set name "ZTNA-Allow-Simple"
        set srcintf "port3"
        set dstintf "any"
        set action accept
        set srcaddr "all"
        set dstaddr "ZTNA-webserver"
        set ztna-ems-tag "EMS1_CLASS_Low"
        set schedule "always"
        set logtraffic all
```

```

    set nat enable
  next
end

```

For configuration examples using full ZTNA policy, see [Configure a ZTNA policy on page 1065](#).

Testing the remote access to the HTTPS access proxy

After FortiClient EMS and FortiGate are configured, the HTTPS access proxy remote connection can be tested.

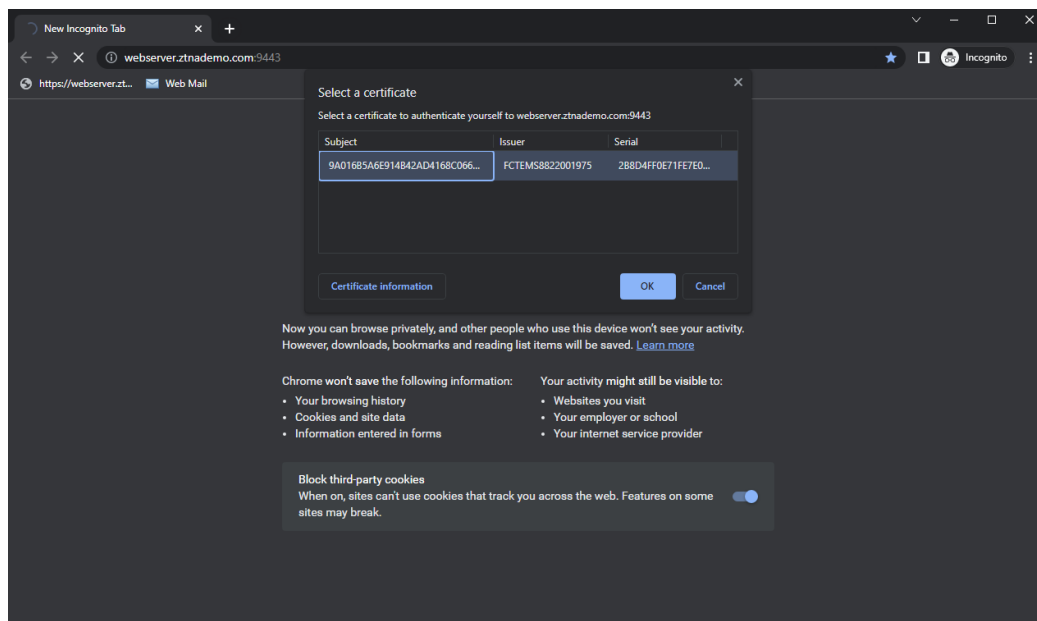

Access allowed:

1. On the remote Windows PC, open FortiClient.
2. On the *Zero Trust Telemetry* tab, make sure that you are connected to the EMS server.

It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.

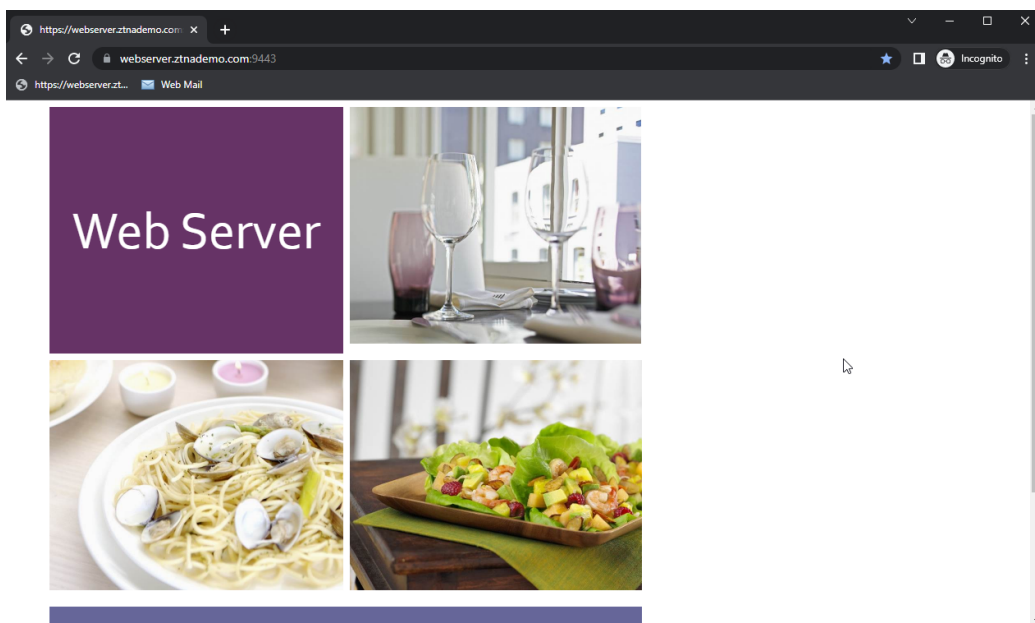

3. Open a browser and enter the address of the server and the access port. When entering the FQDN, make sure that the DNS can resolve the address to the IP address of the FortiGate. In this example, `webserver.ztnademo.com` resolves to `10.0.3.10`.
4. The browser prompts for the client certificate to use. Select the EMS signed certificate, then click *OK*.

The certificate is in the *User Configuration* store, under *Personal > Certificates*. The details show the SN of the certificate, which matches the record on the FortiClient EMS and the FortiGate.

5. The client is verified by the FortiGate to authenticate your identity.
6. The FortiGate matches your security posture by verifying your ZTNA tag and matching the corresponding ZTNA rule, and you are allowed access to the web server.

Access denied:

1. On the remote Windows PC, trigger the Zero Trust Tagging Rule by creating the file in C:\virus.txt.
2. Open a browser and enter the address <http://webserver.ztnademo.com:9443>.
3. The client is verified by the FortiGate to authenticate your identity.
4. FortiGate checks your security posture. Because EMS has tagged the PC with the *Malicious-File-Detected* tag, it matches the *ZTNA-Deny-malicious* rule.

5. You are denied access to the web server.

Logs and debugs

ZTNA HTTPS access proxy with basic authentication example

This example expands on the previous example ([ZTNA HTTPS access proxy example on page 1102](#)), adding LDAP authentication to the ZTNA rule. Users are allowed based on passing the client certificate authentication check, user authentication, and security posture check.

Users that are in the AD security group *ALLOWED-VPN* are allowed access to the access proxy. Users that are not part of this security group are not allowed access.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

LDAP/Active Directory Users and Groups:

- Domain: fortiad.info
- Users (Groups):
 - tsmith (Domain Users, Remote-Allowed)
 - lhansen (Domain Users)

To configure a secure connection to the LDAP server in the GUI:

1. Go to *User & Authentication > LDAP Servers* and click *Create New*.
2. Configure the following settings:

Name	LDAP-fortiad
Server IP/Name	10.88.0.1
Server Port	636
Common Name Identifier	sAMAccountName

Distinguished Name	dc=fortiad,dc=info
Exchange server	Disabled
Bind Type	Regular Enter the <i>Username</i> and <i>Password</i> for LDAP binding and lookup.
Secure Connection	Enabled <ul style="list-style-type: none"> Set <i>Protocol</i> to <i>LDAPS</i> Enable <i>Certificate</i> and select the CA certificate to validate the server certificate.
Server identity check	Optionally, enable to verify the domain name or IP address against the server certificate.

3. Click *Test Connectivity* to verify the connection to the server.
4. Click *OK*.

To configure a secure connection to the LDAP server in the CLI:

```
config user ldap
  edit "LDAP-fortiad"
    set server "10.88.0.1"
    set cnid "sAMAccountName"
    set dn "dc=fortiad,dc=info"
    set type regular
    set username "fortiad\\Administrator"
    set password <password>
    set secure ldaps
    set ca-cert "CA_Cert_1"
    set port 636
  next
end
```

To configure a remote user group from the LDAP server in the GUI:

1. Go to *User & Authentication > User Groups* and click *Create New*.
2. Set the name to *LDAP-Remote-Allowed-Group*.
3. Set *Type* to *Firewall*.
4. In the *Remote Groups* table click *Add*:
 - a. Set *Remote Server* to *LDAP-fortiad*.
 - b. Locate the *Remote-Allowed* group, right-click on it, and click *Add Selected*.
 - c. Click *OK*.

The screenshot shows the 'Edit User Group' configuration window in the FortiGate GUI. The 'Name' field is set to 'LDAP-Remote-Allowed-Group' and the 'Type' is 'Firewall'. Below these fields is a 'Members' section with a plus icon. The 'Remote Groups' section contains a table with two columns: 'Remote Server' and 'Group Name'. One entry is visible: 'LDAP-fortiad' with the group name 'CN=Remote-Allowed,CN=Users,DC=fortiad,DC=info'. To the right of the table are buttons for '+ Add', 'Edit', and 'Delete'. On the far right, there's a sidebar with 'FortiGate' information, a 'Send SSL-VPN Configuration' button, and a section for 'Additional Information' with links to 'API Preview', 'References', 'Edit in CLI', 'Online Guides', 'Relevant Documentation', 'Video Tutorials', 'Hot Questions at FortiAnswers', and 'Join the Discussion'. At the bottom of the window are 'OK' and 'Cancel' buttons.

5. Click *OK*.

To configure a remote user group from the LDAP server in the CLI:

```
config user group
  edit "LDAP-Remote-Allowed-Group"
    set member "LDAP-fortiad"
    config match
      edit 1
        set server-name "LDAP-fortiad"
        set group-name "CN=Remote-Allowed,CN=Users,DC=fortiad,DC=info"
      next
    end
  next
end
```

Authentication scheme and rules

After the LDAP server and user group have been configured, an authentication scheme and rule must be configured.

To configure authentication schemes and rules in the GUI, go to *System > Feature Visibility* and enable *Explicit Proxy*.

Authentication scheme

The authentication scheme defines the method of authentication that is applied. In this example, basic HTTP authentication is used so that users are prompted for a username and password the first time that they connect to a website through the HTTPS access proxy.

To configure an authentication scheme in the GUI:

1. Go to *Policy & Objects > Authentication Rules* and click *Create New > Authentication Scheme*.
2. Set the name to *ZTNA-Auth-scheme*.
3. Set *Method* to *Basic*.
4. Set *User database* to *Other* and select *LDAP-fortiad* as the LDAP server.

5. Click **OK**.

To configure an authentication scheme in the CLI:

```
config authentication scheme
  edit "ZTNA-Auth-scheme"
    set method basic
    set user-database "LDAP-fortiad"
  next
end
```

Authentication rule

The authentication rule defines the proxy sources and destination that require authentication, and what authentication scheme is applied. In this example, active authentication through the basic HTTP prompt is used and applied to all sources.

To configure an authentication rule in the GUI:

1. Go to *Policy & Objects > Authentication Rules* and click *Create New > Authentication Rule*.
2. Set the name to *ZTNA-Auth-rule*.
3. Set *Source Address* to *all*.
4. Set *Protocol* to *HTTP*.
5. Enable *Authentication Scheme* and select *ZTNA-Auth-scheme*.
6. Click **OK**.

To configure an authentication rule in the CLI:

```
config authentication rule
    edit "ZTNA-Auth-rule"
        set srcaddr "all"
        set active-auth-method "ZTNA-Auth-scheme"
    next
end
```

Applying the user group to a ZTNA policy

A user or user group must be applied to the ZTNA policy that you need to control user access to. The authenticated user from the authentication scheme and rule must match the user or user group in the ZTNA policy.

In this example, the user group is applied to the two simple ZTNA policies that were configured in [ZTNA HTTPS access proxy example on page 1102](#).

To apply a user group to the simple ZTNA policies in the GUI:

1. Go to *Policy & Objects > Firewall Policy*.
2. Edit the *ZTNA-Deny-malicious* rule.
3. Click in the *Source* field, select the *User* tab, select the *LDAP-Remote-Allowed-Group* group, then click *Close*.
4. Click *OK*.
5. Edit the *ZTNA-Allow-Simple* rule.
6. Click in the *Source* field, select the *User* tab, select the *LDAP-Remote-Allowed-Group* group, then click *Close*.
7. Click *OK*.

To apply a user group to the simple ZTNA policies in the CLI:

```
config firewall policy
    edit 9
        set name "ZTNA-Deny-Malicious"
        set srcintf "port3"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "ZTNA-webserver"
        set ztna-ems-tag "EMS1_ZTNA_Malicious-File-Detected"
        set schedule "always"
        set logtraffic all
        set groups "LDAP-Remote-Allowed-Group"
    next
    edit 10
        set name "ZTNA-Allow-Simple"
        set srcintf "port3"
        set dstintf "any"
        set action accept
        set srcaddr "all"
        set dstaddr "ZTNA-webserver"
        set ztna-ems-tag "EMS1_CLASS_Low"
        set schedule "always"
        set logtraffic all
        set nat enable
```

```

        set groups "LDAP-Remote-Allowed-Group"
    next
end

```

For configuration examples using full ZTNA policy, see [Configure a ZTNA policy on page 1065](#).

Testing remote access to the HTTPS access proxy with user authentication

Scenario 1: access allowed - user tsmith

1. On a remote Windows PC, open the FortiClient app, select the *Zero Trust Telemetry* tab, and confirm that you are connected to the EMS server.

It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.

2. In a browser, enter the address of the server and the access port.
If entering an FQDN, make sure that DNS can resolve the address to the IP address of the FortiGate. In this example, *webserver.ztnademo.com* resolves to 10.0.3.10.
3. When the browser asks for the client certificate to use, select the EMS signed certificate, then click *OK*.
The client certificate is verified by the FortiGate to authenticate your identity.
4. When prompted, enter the username *tsmith* and the password, and click *Sign in*.
As *tsmith* is a member of the *Remote-Allowed-Group* group in Active Directory, it will match the *LDAP-Remote-Allowed-Group* user group. After the user authentication passes, the FortiGate performs a posture check on the ZTNA group. When that passes, you are allowed access to the website.

Verifying the results

```

# diagnose firewall auth list

10.0.3.2, tsmith
  type: fw, id: 0, duration: 12, idled: 12
  expire: 288, allow-idle: 300
  packets: in 0 out 0, bytes: in 0 out 0
  group_id: 3
  group_name: LDAP-Remote-Allowed-Group

# diagnose test app fcnacd 7

```

Scenario 2: access denied – user lhansen

- If scenario 1 has just been tested, log in to the FortiGate and deauthenticate the user:
 - Go to *Dashboard > Assets & Identities* and expand the *Firewall Users* widget.
 - Right-click on the user *tsmith* and select deauthenticate.
- On a remote Windows PC, open the FortiClient app, select the *Zero Trust Telemetry* tab, and confirm that you are connected to the EMS server.
- In a browser, enter the address *webserver.ztnademo.com*.
- When the browser asks for the client certificate to use, select the EMS signed certificate, then click *OK*. This option might not appear if you have already selected the certificate when testing scenario 1.
The client certificate is verified by the FortiGate to authenticate your identity.
- When prompted, enter the username *lhansen* and the password, and click *Sign in*.
As *lhansen* is not a member of the *Remote-Allowed* group in Active Directory, it will not match the *LDAP-Remote-Allowed-Group* user group. Because no other policies are matched, this user is implicitly denied

Verifying the results

Go to *Dashboard > Assets & Identities*, expand the *Firewall Users* widget, and confirm that user *lhansen* is listed, but no applicable user group is returned.

```
# execute log display
```

```

ZTNA TCP forwarding access proxy example

In this example, a TCP forwarding access proxy (TFAP) is configured to demonstrate an HTTPS reverse proxy that forwards TCP traffic to the designated resource. The access proxy tunnels TCP traffic between the client and the FortiGate over HTTPS, and forwards the TCP traffic to the protected resource. It verifies user identity, device identity, and trust context, before granting access to the protected source.

TCP forwarding access proxy supports communication between the client and the access proxy without SSL/TLS encryption. The connection still begins with a TLS handshake. The client uses the HTTP 101 response to switch protocols and remove the HTTPS stack. Further end to end communication between the client and server are encapsulated in the specified TCP port, but not encrypted by the access proxy. This improves performance by reducing the overhead of encrypting an already secured underlying protocol, such as RDP, SSH, or FTPS. Users should still enable the encryption option for end to end protocols that are insecure.

In this example, RDP (Remote Desktop Protocol) and SMB (Server Message Block) protocol access are configured to one server, and SSH access to the other server. Encryption is disabled for RDP and SSH, and enabled for SMB.

FortiClient (Windows) must be running 7.0.3 or later to detect SMB.

You cannot use ZTNA connection rules and TCP forwarding on a Windows 7 endpoint.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

To configure the ZTNA server for TCP access proxy in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Set *Name* to *ZTNA-tcp-server*.
4. Configure the network settings:
 - a. Set *External interface* to *port3*.
 - b. Set *External IP* to *10.0.3.11*.
 - c. Set *External port* to *8443*.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.
6. Add server mapping:
 - a. In the *Service/server mapping* table, click *Create New*.
 - b. Set *Service* to *TCP Forwarding*.
 - c. Add a server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Create a new address for the FortiAnalyzer server at 10.88.0.2 and use it as the address.
 - iii. Set *Port* to 22.
 - iv. Click *OK*.
 - d. Add another server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Create a new address for the winserver at 10.88.0.1 and use it as the address.
 - iii. Set *Port* to 445, 3389 to correspond to SMB and RDP.
 - iv. Click *OK*.
 - e. Click *OK*.
7. Click *OK*.

To configure a simple ZTNA policy to allow traffic to the TCP access proxy in the GUI:

1. Go to *Policy & Objects > Firewall Policy*, and click *Create New*.
2. Set *Name* to *ZTNA_remote*.
3. Set *Type* to *ZTNA*.
4. Set *Incoming Interface* to *port3*.
5. Set *Source* to *all*.
6. Select the ZTNA server *ZTNA-tcp-server*.
7. Configure the remaining options as needed.
8. Click *OK*.

To configure the access proxy VIP in the CLI:

```
config firewall vip
  edit "ZTNA-tcp-server"
    set type access-proxy
```

```
        set extip 10.0.3.11
        set extintf "port3"
        set server-type https
        set extport 8443
        set ssl-certificate "Fortinet_SSL"
    next
end
```

To configure the server addresses in the CLI:

```
config firewall address
    edit "FAZ"
        set subnet 10.88.0.2 255.255.255.255
    next
    edit "winserver"
        set subnet 10.88.0.1 255.255.255.255
    next
end
```

To configure access proxy server mappings in the CLI:

```
config firewall access-proxy
    edit "ZTNA-tcp-server"
        set vip "ZTNA-tcp-server"
        config api-gateway
            edit 1
                set url-map "/tcp"
                set service tcp-forwarding
                config realservers
                    edit 1
                        set address "FAZ"
                        set mappedport 22
                    next
                    edit 2
                        set address "winserver"
                        set mappedport 445 3389
                    next
                end
            next
        end
    next
end
next
end
```

The mapped port (`mappedport`) restricts the mapping to the specified port or port range. If `mappedport` is not specified, then any port will be matched.

To configure a ZTNA rule (proxy policy) in the CLI:

```
config firewall policy
    edit 11
        set name "ZTNA_remote"
        set srcintf "port3"
        set dstintf "any"
        set action accept
        set srcaddr "all"
        set dstaddr "ZTNA-tcp-server"
```

```

set schedule "always"
set logtraffic all
set nat enable
next
end

```

For configuration examples using full ZTNA policy, see [Configure a ZTNA policy on page 1065](#).

Test the connection to the access proxy

Before connecting, users must have a ZTNA connection rule in FortiClient.

ZTNA TCP forwarding rules can be provisioned from the EMS server. See [Provisioning ZTNA TCP forwarding rules via EMS](#) for details.

To create a ZTNA Destination in FortiClient:

1. On the *ZTNA Destination* tab, click *Add Destination*.
2. Set *Destination Name* to *SSH-FAZ*.
3. Set *Destination Host* to *10.88.0.2:22*. This is the real IP address and port of the server.
4. Set *Proxy Gateway* to *10.0.3.11:8443*. This is the access proxy address and port that are configured on the FortiGate.
5. Leave *Encryption* disabled. This option determines whether or not the Client to FortiGate access proxy connection is encrypted in HTTPS.

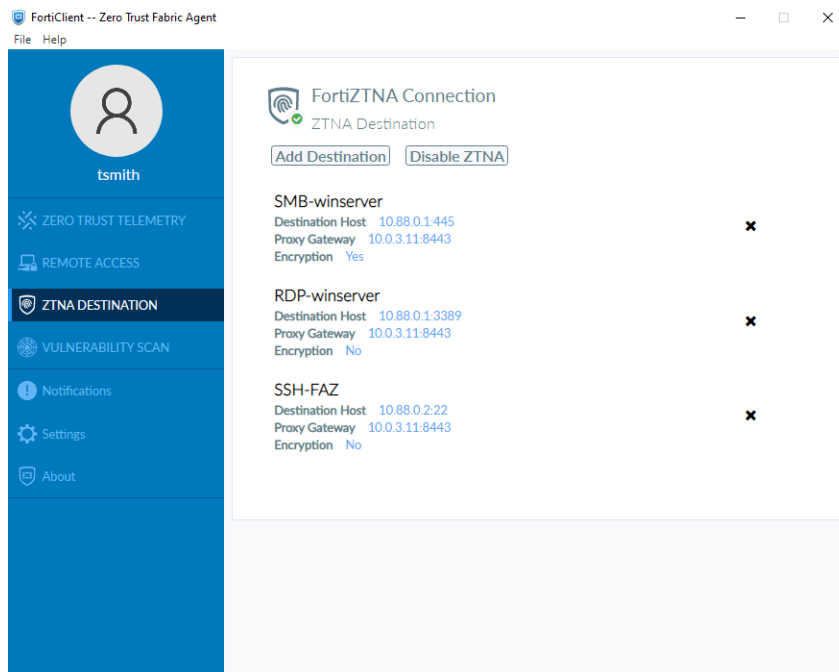

6. Click *Create*.
7. Create a second rule with the following settings:

- *Rule Name:* RDP-winservice
- *Destination Host:* 10.88.0.1:3389
- *Proxy Gateway:* 10.0.3.11:8443
- *Encryption:* Disabled

8. Create a third rule with the following settings:

- *Rule Name:* SMB-winservice
- *Destination Host:* 10.88.0.1:445
- *Proxy Gateway:* 10.0.3.11:8443
- *Encryption:* Enabled

After creating the ZTNA connection rules, you can SSH, RDP, and SMB directly to the server IP address and port.

ZTNA SSH access proxy example

ZTNA can be configured with SSH access proxy to provide a seamless SSH connection to the server.

Advantages of using an SSH access proxy instead of a TCP forwarding access proxy include:

- Establishing device trust context with user identity and device identity checks.
- Applying SSH deep inspection to the traffic through the SSH related profile.
- Performing optional SSH host-key validation of the server.
- Using one-time user authentication to authenticate the ZTNA SSH access proxy connection and the SSH server connection.

Perform SSH host-key validation of the server

To act as a reverse proxy for the SSH server, the FortiGate must perform SSH host-key validation to verify the identity of the SSH server. The FortiGate does this by storing the public key of the SSH server in its SSH host-key configurations. When a connection is made to the SSH server, if the public key matches one that is used by the server, then the connection is established. If there is no match, then the connection fails.

One-time user authentication

SSH access proxy allows user authentication to occur between the client and the access proxy, while using the same user credentials to authenticate with the SSH server. The following illustrates how this works:

1. The remote endpoint registers to FortiClient EMS and receives the client certificate.
2. The remote endpoint tries to connect to the SSH access proxy. It must use the same username that is later used for access proxy authentication.
3. The FortiGate challenges the endpoint with device identity validation.
4. The remote endpoint provides the EMS issued certificate for device identification.
5. The FortiGate challenges the endpoint with user authentication. For example, this could be done with basic or SAML authentication.
6. The user enters their credentials on the remote endpoint.
7. The FortiGate authenticates the user and collects the username.
8. Using the FortiGate's CA or the customer's CA certificate, the FortiGate signs an SSH certificate and embeds the username in its principal.
9. The FortiGate attempts to connect to the SSH server using the certificate authentication.
10. The SSH server verifies the authenticity of the certificate, and matches the username principal against its `authorized_keys` file.
11. If the username matches a record in the file, then the SSH connection is established. If no match is found, then the SSH connection fails.

Example

In this example, an SSH connection is established using SSH access proxy with host-key validation and one-time authentication.

- The SSH server is a Linux based server that uses `sshd` to provide remote access
- For SSH host-key validation, the public key of the SSH server has been imported into the FortiGate.
- For one-time authentication using certificate authentication:
 - The SSH server must allow certificate authentication.
 - The SSH server must have the proper entry in its `authorized_keys` file that contains the user principal and the FortiGate CA's public key.
 - The entry is present in the user directory corresponding to the user that is trying to log in.

To pre-configure the Linux SSH server:**1. Retrieve the public key used for host-key validation:****a. Locate the public key files in the SSH server:**

```
$ ls -la /etc/ssh/*.pub
-rw-r--r-- 1 root root 186 Mar 29 2020 /etc/ssh/ssh_host_ecdsa_key.pub
-rw-r--r-- 1 root root 106 Mar 29 2020 /etc/ssh/ssh_host_ed25519_key.pub
-rw-r--r-- 1 root root 406 Mar 29 2020 /etc/ssh/ssh_host_rsa_key.pub2
```

b. Choose the public key file based on the hash type (in this case, ECDSA), and show its content:

```
$ cat /etc/ssh/ssh_host_ecdsa_key.pub
ecdsa-sha2-nistp256 AAAAE2*****IpEik=
```

This key will be used when configuring the FortiGate.

2. Retrieve the FortiGate CA's public key from the FortiGate:

```
# show full firewall ssh local-ca Fortinet_SSH_CA
config firewall ssh local-ca
  edit "Fortinet_SSH_CA"
    set password ENC <hidden password>
    set private-key "-----BEGIN OPENSSH PRIVATE KEY-----
<hidden private key>
-----END OPENSSH PRIVATE KEY-----"
    set public-key "ssh-rsa AAAAB3*****JLX1xj3"
    set source built-in
  next
end
```

3. On the Linux server, enable the SSH service to use the authorized_keys file:**a. Locate and edit the /etc/ssh/sshd_config file.****b. Ensure that the AuthorizedKeysFile line is uncommented, for example:**

```
AuthorizedKeysFile      .ssh/authorized_keys .ssh/authorized_keys2
```

4. Allow remote SSH log in with certificate authentication and principal name:**a. Log in to the SSH server using the account that will be granted remote SSH access (in this example: radCurtis):****b. Locate the account's authorized_keys file in the ~/.ssh directory:**

```
$ ls -la ~/.ssh
total 12
drwxrwxr-x 2 radCurtis radCurtis 4096 Aug 10 19:14 .
drwxr-xr-x 5 radCurtis radCurtis 4096 Aug 10 19:13 ..
-rw-rw-r-- 1 radCurtis radCurtis  419 Aug 10 19:14 authorized_keys
```

c. If the directory and file do not exist, create the directory:

```
$ mkdir ~/.ssh
```

d. Create an entry containing the following keywords and add them to the authorized_keys file:

```
echo 'cert-authority,principals="radCurtis" ssh-rsa AAAAB3*****JLX1xj3' >>
authorized_keys
```

Where:

- **cert-authority** - indicates that this entry is used in certificate authentication by validating the certificate using the public key provided in this entry.

- `principals="radCurtis"` - indicates the user that must match with the username embedded in the SSH certificate.
- `ssh-rsa AAAAB3*****JLXlxj3` - indicates the FortiGate CA's public key that is used to validate the SSH certificate.

5. Restart the sshd service:

```
$ sudo systemctl stop sshd
$ sudo systemctl start sshd
```

The SSH server can now accept SSH connection from `radCurtis@<server IP>`, where the SSH certificate used by the FortiGate to log in contains `radCurtis` embedded as a principal.

When a user connects from a SSH client using `<username>@<server IP>`, `sshd` will locate the `authorized_keys` file in the directory `/home/<username>/.ssh/authorized_keys`. If the `authorized_keys` is not in that directory, authentication will fail on the SSH server side.

If you suspect that authentication is failing on the SSH server, use the following commands to manually start `sshd` in debug mode to troubleshoot:

```
$ sudo systemctl stop sshd
$ /usr/sbin/sshd -ddd -p 22
```

To configure the FortiGate :

1. Configure a new VIP to allow access to the SSH access proxy over 192.168.2.87:443:

```
config firewall vip
  edit "ZTNA_SSH"
    set type access-proxy
    set extip 192.168.2.87
    set extintf "any"
    set server-type https
    set extport 443
    set ssl-certificate "Fortinet_SSL"
  next
end
```

2. Configure the address object for the SSH server:

```
config firewall address
  edit "SSH_server"
    set subnet 192.168.20.1 255.255.255.255
  next
end
```

3. Configure the host-key that will be used to authenticate the SSH server. The public-key was retrieved when pre-configure the Linux SSH server (step 1b).

```
config firewall ssh host-key
  edit "ed25519"
    set type ECDSA
    set usage access-proxy
    set public-key "AAAAB3*****IpEik="
  next
end
```

4. Configure the access proxy SSH client certificate:

A CA certificate is assigned to sign the SSH certificate that will be used in the SSH authentication. The SSH certificate will have the username embedded in the certificate principal.

```
config firewall access-proxy-ssh-client-cert
    edit "ssh-access-proxy"
        set source-address enable
        set auth-ca "Fortinet_SSH_CA"
    next
end
```

5. Configure the access-proxy server setting:

```
config firewall access-proxy
    edit "ZTNA_SSH"
        set vip "ZTNA_SSH"
        set client-cert enable
        config api-gateway
            edit 1
                set url-map "tcp"
                set service tcp-forwarding
                config realservers
                    edit 1
                        set address "SSH_server"
                        set type ssh
                        set ssh-client-cert "ssh-access-proxy"
                        set ssh-host-key-validation enable
                        set ssh-host-key "ed25519"
                    next
                end
            next
        end
    next
end
```

6. Configure the RADIUS setting, user setting, and user group to apply user authentication to the access proxy connection using RADIUS:

```
config user radius
    edit "Win2k16-Radius"
        set server "192.168.20.6"
        set secret ENC <secret>
    next
end
config user local
    edit "radCurtis"
        set type radius
        set radius-server "Win2k16-Radius"
    next
end
config user group
    edit "radius_group"
        set member "radCurtis" "Win2k16-Radius"
    next
end
```

7. Create the authentication scheme and rule to perform the authentication:

```

config authentication scheme
    edit "basic_auth"
        set method basic
        set user-database "Win2k16-Radius"
    next
end
config authentication rule
    edit "ztna-basic"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "basic_auth"
        set web-auth-cookie enable
    next
end

```

8. Configure the full ZTNA policy to allow traffic to the SSH server, and apply user authentication, posture check, and a security profile where necessary:

```

config firewall proxy-policy
    edit 5
        set name "SSH-proxy"
        set proxy access-proxy
        set access-proxy "ZTNA_SSH"
        set srcintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set ztna-ems-tag "FCTEMS8821001056_ems138_av_tag"
        set action accept
        set schedule "always"
        set groups "radius_group"
        set utm-status enable
        set ssl-ssh-profile "custom-deep-inspection"
    next
end

```

To check the results:

1. On the remote client, open FortiClient, go to the *Zero Trust Telemetry* tab, and make sure that it is connected to the EMS server.
2. Go to the *ZTNA Destination* tab and click *Add Destination*.
3. Configure the Destination, then click *Create*:

Rule Name	SSH-Linux
Destination Host	192.168.20.1:22
Proxy Gateway	192.168.2.87:443
Mode	Transparent
Encryption	Disabled (recommended)

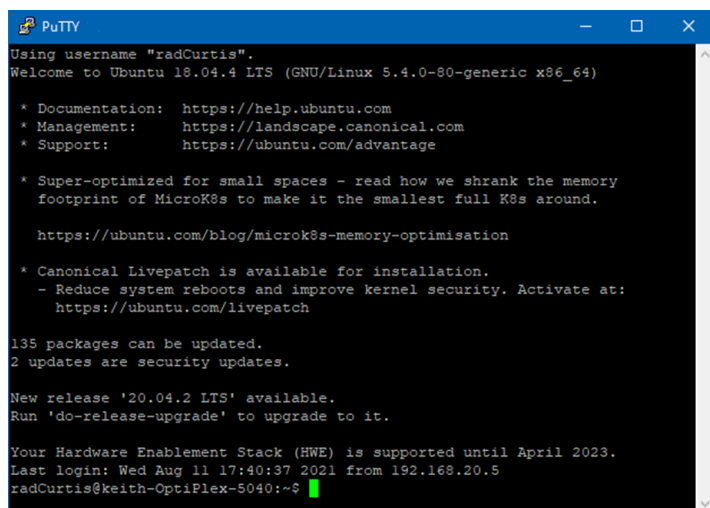

When Encryption is disabled, the connection between the client and FortiGate access proxy is not encapsulated in HTTPS after the client and FortiGate connection is established. This allows for less overhead, because SSH is already a secure connection.

4. Open an SSH client, such as PuTTY, and make an SSH connection to *radCurtis@192.168.20.1* on port 22.

5. After device authentication is performed and passes in the background, FortiClient prompts the user to sign in. Enter the username, *radCurtis*, and password, then click *Sign in*.

After successful user authentication, the SSH connection is established without an additional log in.

6. On the FortiGate, check the logged in user:
 - a. Go to *Dashboard > Assets & Identities* and expand the *Firewall Users* widget.
 - b. Check the WAD proxy user list:

```
# diagnose wad user list
ID: 2, VDOM: root, IPv4: 10.10.10.25
  user name   : radCurtis
  worker      : 0
  duration    : 614
  auth_type   : Session
  auth_method : Basic
  pol_id      : 5
  g_id        : 12
  user_based  : 0
  expire      : 53
LAN:
  bytes_in=3403 bytes_out=5699
WAN:
  bytes_in=3681 bytes_out=3132
```

7. The successful connection is logged in the forward traffic logs after the SSH connection has disconnected:

```
# execute log display
25 logs found.
10 logs returned.

1: date=2021-08-11 time=17:59:56 eventtime=1628729996110159120 tz="-0700"
logid="0000000024" type="traffic" subtype="forward" level="notice" vd="root"
```

```
srcip=10.10.10.25 srcport=50627 srcintf="port1" srcintfrole="wan" dstcountry="Reserved"

```

ZTNA application gateway with SAML authentication example

In this example, an HTTPS access proxy is configured, and SAML authentication is applied to authenticate the client. The FortiGate acts as the SAML SP and a SAML authenticator serves as the IdP. In addition to verifying the user and device identity with the client certificate, the user is also authorized based on user credentials to establish a trust context before granting access to the protected resource.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

To configure the access proxy VIP:

```
config firewall vip
    edit "ZTNA_server01"
        set type access-proxy
        set extip 172.18.62.32
        set extintf "any"
        set server-type https
        set extport 7831
        set ssl-certificate "Fortinet_CA_SSL"
    next
end
```

To configure access proxy server mappings:

```
config firewall access-proxy
    edit "ZTNA_server01"
        set vip "ZTNA_server01"
        set client-cert enable
        config api-gateway
            edit 1
                set service https
                config realservers
                    edit 1
                        set ip 172.18.62.25
                        set port 443

```

```
        next
    end
    next
end
next
end
```

To configure a SAML server:

```
config user saml
    edit "saml_ztna"
        set cert "Fortinet_CA_SSL"
        set entity-id "https://fgt9.myqalab.local:7831/samlap"
        set single-sign-on-url "https://fgt9.myqalab.local:7831/XX/YY/ZZ/saml/login/"
        set single-logout-url "https://fgt9.myqalab.local:7831/XX/YY/ZZ/saml/logout/"
        set idp-entity-id "http://MYQALAB.LOCAL/adfs/services/trust"
        set idp-single-sign-on-url "https://myqalab.local/adfs/ls"
        set idp-single-logout-url "https://myqalab.local/adfs/ls"
        set idp-cert "REMOTE_Cert_4"
        set digest-method sha256
        set adfs-claim enable
        set user-claim-type upn
        set group-claim-type group-sid
    next
end
```

To map the SAML server into an access proxy configuration:

```
config firewall access-proxy
    edit "ZTNA_server01"
        config api-gateway
            edit 3
                set service samlsp
                set saml-server "saml_ztna"
            next
        end
    next
end
```

To configure an LDAP server and an LDAP server group to verify user groups:

```
config user ldap
    edit "ldap-10.1.100.198"
        set server "10.1.100.198"
        set cnid "cn"
        set dn "dc=myqalab,dc=local"
        set type regular
        set username "cn=fosqal,cn=users,dc=myqalab,dc=local"
        set password *****
        set group-search-base "dc=myqalab,dc=local"
    next
end

config user group
    edit "ldap-group-saml"
        set member "ldap-10.1.100.198"
```

```
    next
end
```

To configure the authentication rule and scheme to match the new SAML server:

```
config authentication rule
    edit "saml_ztna"
        set srcintf "port10"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "saml_ztna"
        set web-auth-cookie enable
    next
end

config authentication scheme
    edit "saml_ztna"
        set method saml
        set saml-server "saml_ztna"
        set saml-timeout 30
        set user-database "ldap-10.1.100.198"
    next
end
```

To enable user group authentication in an access-proxy type firewall proxy-policy:

```
config firewall proxy-policy
    edit 6
        set name "ZTNA_remote"
        set proxy access-proxy
        set access-proxy "ZTNA_server01"
        set srcintf "any"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set groups "ldap-group-saml"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
    next
end
```

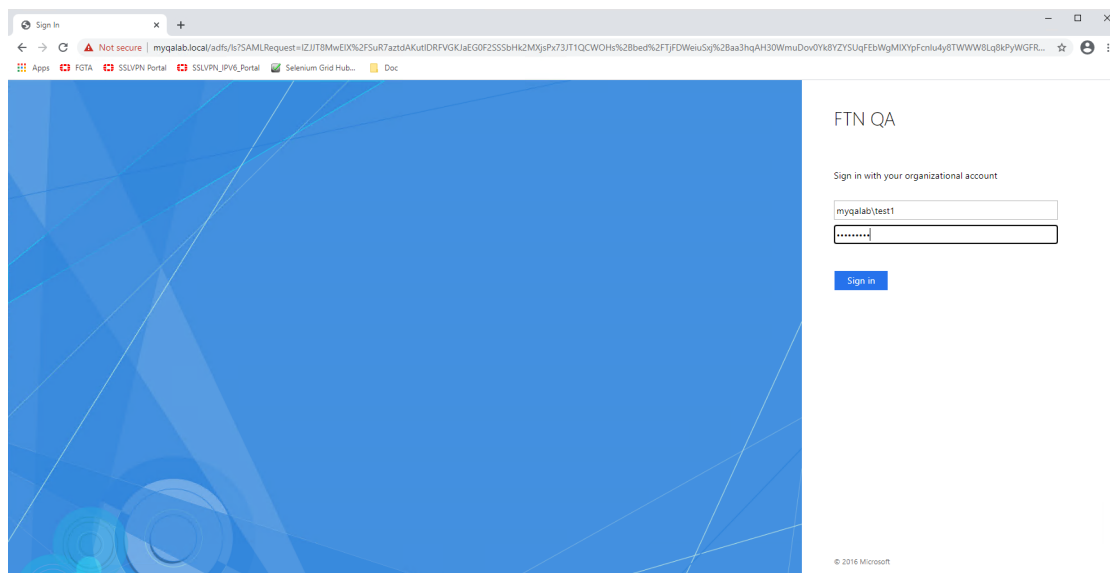

Testing the connection

To test the connection:

It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.

1. On a client PC, try to access the webpage through the HTTPS access proxy. For example, go to `http://172.18.62.32:7831` in a browser.

- The client PC is prompted for a client certificate. After the certificate is validated, you are redirected to a SAML log in portal.

- Enter your user credentials. The SAML server authenticates and sends a SAML assertion response message to the FortiGate.
- The FortiGate queries the LDAP server for the user group, and then verifies the user group against the groups or groups defined in the proxy policy.
- The user is proxied to the webpage on the real web server.

Logs and debugs

Use the following command to check the user information after the user has been authenticated:

```
# diagnose wad user list
ID: 7, VDOM: vdom1, IPv4: 10.1.100.143
  user name   : test1@MYQALAB.local
  worker      : 0
  duration    : 124
  auth_type   : Session
  auth_method : SAML
  pol_id      : 6
  g_id        : 13
  user_based  : 0
  expire      : no
LAN:
  bytes_in=25953 bytes_out=14158
WAN:
  bytes_in=8828 bytes_out=6830
```

Event log:

```
1: date=2021-03-24 time=19:02:21 eventtime=1616637742066893182 tz="-0700" logid="0102043025"

ZTNA application gateway with SAML and MFA using FortiAuthenticator example

ZTNA application gateway supports device verification using device certificates that are issued by EMS. To authenticate users, administrators can use either basic or SAML authentication. An advantage of SAML authentication is that multi-factor authentication (MFA) can be provided by the SAML Identity Provider (IdP).
